INTRODUCTION

The motivation for our work stems from the questions posed by F. Enriques in Chapter VIII of his book "Le superficie algebriche" ([Enr]) about surfaces of general type with $p_g = 4$ and their moduli.

For these, $K^2 \geq 4$, and the cases $K^2 = 4, 5$ were completely classified by Enriques(cf. [Enr]). Enriques also discussed at length the case $K^2 = 6$, which was later completely classified by Horikawa in [Hor3].

The first question posed by Enriques was the following: for which value of $K^2$ does there exist a surface with $p_g = 4$ and birational canonical map? This existence question, posed by Enriques for $K^2 \geq 8$, was later solved by virtue of the contributions of several authors, and we now know that such surfaces exist for $7 \leq K^2 \leq 32$, (cf. e.g. [Cil], [Cat2]).

The answer to the question concerning classification and moduli is much harder, and a complete classification has been achieved up to now only for $K^2 \leq 7$, see for instance the monograph ([Bauer]) for the case $K^2 = 7$.

The challenging open problem for $K^2 = 6, 7$ is to completely understand the structure of the moduli space, i.e., to determine the incidence correspondence of the several locally closed strata which are described in the classification.

The research of the authors was performed in the realm of the DFG SCHWERPUNKT "Globale Methode in der komplexen Geometrie", and of the EAGER EEC Project. The third author was supported by the Schwerpunkt and by P.R.I.N. 2002 "Geometria delle variet algebriche" of M.I.U.R. and is a member of G.N.S.A.G.A. of I.N.d.A.M.
Horikawa showed in [Hor1] that the moduli space for \( K^2 = 5 \) is connected, with two irreducible components of dimension 40 meeting along a divisor.

He showed later (Hor3) that for \( K^2 = 6 \) there are exactly four irreducible components and at most three connected components. He did so by first listing all possibilities for the canonical map, dividing thus the moduli space of surfaces with \( K^2 = 6 \) into 11 nonempty locally closed strata, and then analysing some of their local deformations.

More precisely, Horikawa named the 11 strata \( I_a, I_b, II, III_a, III_b, IV_{a_1}, IV_{a_2}, IV_{b_1}, IV_{b_2}, V_1, V_2 \) (see [Hor3] or (1.3) below for precise definitions of each stratum). According to Horikawa’s notation we define

**Notation.** Let \( A \) and \( B \) be two of the above introduced strata. The notation “\( A \to B \)” means that \( B \) intersects the closure of \( A \), i.e., there is a deformation of a surface of type \( B \) to surfaces of type \( A \) (it suffices to have a flat family over a small disk \( \Delta_\varepsilon \subset \mathbb{C} \) whose central fibre is of type \( B \) and whose general fibre is of type \( A \)).

With this notation Horikawa summarized his results in the following diagram

\[
\begin{array}{c}
III_a \\
\downarrow \\
IV_{a_1} & I_a & V_1 & \downarrow \\
\downarrow & \downarrow & \downarrow & \downarrow \\
IV_{a_2} & IV_{b_1} & V_2 & I_b \\
\downarrow & \downarrow & \downarrow & \\
IV_{b_2} & & \\
\end{array}
\]

Our main result is:

**Theorem 0.1.** Consider the moduli space of surfaces with \( p_g = 4, K^2 = 6 \). Then it has at most two connected components.

In particular, \( II \to III_b \), i.e., there is a deformation of surfaces of type \((III_b)\) to surfaces of type \((II)\).

We would moreover like to pose the following

**Question 0.2.** It the above moduli space (for \( p_g = 4, K^2 = 6 \)) disconnected?

A possible reason for this could be that the surfaces of all irreducible components degenerate to surfaces with a genus two pencil, but in one case the braid monodromy is transitive, in the other case it is not.

The new idea that we exploit is the following: the canonical models \( X \) of surfaces of Type \((II)\) are exactly the hypersurfaces of degree 9 in the weighted projective space \( \mathbb{P}(1, 1, 2, 3) \) (with rational double points as singularities). This remark was used in [Cat1] to give a new
explanation of the result of Horikawa that the moduli space is non-reduced on the open set (II), and it implies that the canonical divisor is 2-divisible as a Weil divisor on \( X \).

Similarly occurs for type (III\(_b\)), so for both types of surfaces we have a semicanonical ring \( B \), and what we do is to find a flat family of deformations of the semicanonical ring.

How to do this? The ring \( B \) is a Gorenstein ring, of codimension 1 in case (II), of codimension 4 in case (III\(_b\)), where \( X \) is embedded in \( \mathbb{P}(1,1,2,3,4,5,6) \).

In order to describe the semicanonical ring and its deformations in case (III\(_b\)), we use, as in [BCP], the format of \( 4 \times 4 \) Pfaffians of extrasymmetric antisymmetric \( 6 \times 6 \) matrices.

This format applies to a codimension 2 subvariety of the stratum of surfaces of type (III\(_b\)): these have a pencil of hyperelliptic curves of genus 3, and one has to lift (cf. [Rei2]) this graded ring of dimension 1 to the semicanonical ring of the surface.

The deformation trick is similar to the one used in [BCP] for the canonical ring: filling entries of homogeneous degree 0 in the matrix with parameters (and respecting then the symmetries). When these parameters are non zero, three of the given Pfaffians allow to eliminate the 3 variables of respective weights 4, 5, 6. We obtain then a semicanonical ring of type (II).

We want now to briefly discuss the cited method of extrasymmetric antisymmetric \( 6 \times 6 \) matrices.

The main point here is the lack of a structure theorem for Gorenstein subvarieties of codimension 4 (for codimension 3 we have the celebrated theorem of Buchsbaum and Eisenbud [B-E]).

Several explicit formats were proposed by Dicks, Reid and Papadakis.

The geometric roots (cf. [Rei3]) for the format we use here lie in the fact that the Segre product \( \mathbb{P}^2 \times \mathbb{P}^2 \) is embedded in \( \mathbb{P}^8 \) as the variety of \( 3 \times 3 \) matrices \( A \) of rank 1, hence defined there by 9 quadratic equations, admitting 16 syzygies.

If however one writes \( A = B + C \), with \( C \) symmetric, \( B \) antisymmetric, then one can form the antisymmetric \( 6 \times 6 \)-matrix:

\[
D = \begin{pmatrix} B & C \\ -C & B \end{pmatrix}.
\]

The matrix \( D \) has an extrasymmetry from which follows indeed that the 15 \( (4 \times 4) \) Pfaffians of \( D \) are not independent, but exactly reduce to the above 9 quadratic equations.

Using a flat family of deformations of the above subvariety, and interpreting the entries of the matrix as indeterminates to be specialized, one obtains an easy construction of Gorenstein subvarieties of codimension 4.
We refer to [Rei3] for a thorough discussion of the problem of understanding Gorenstein rings in codimension 4. Our result shows that the "moduli space" of such rings could be rather complicated, since this format does not apply for a general surface of type $(III_b)$, and moreover since we obtain a deformation from codimension 4 to codimension 1, but we observe that one cannot pass through all the lower codimensions.

In the next section we shall determine which of the eleven Horikawa classes yield canonical models $X$ where the canonical divisor is 2-divisible as a Weil divisor (we use here the classical notation $\equiv$ for linear equivalence).

1. Surfaces with 2-divisible canonical divisor

Let $S$ be the minimal model of a surface with $K_S^2 = 6, p_g = 4$, and let $X$ be its canonical model (obtained by contracting the curves $C$ with $K_S \cdot C = 0$).

In this section we shall classify the closed set of the moduli space given by the surfaces for which

(***) there exists a Weil divisor $L$ on $X$ such that $2L \equiv K_X$ and $h^0(X,L) \geq 2$.

Observe that the above hypothesis immediately implies that the image of the canonical map $\phi_{K_X}$ is a quadric cone and that $h^0(X,L) = 2$.

Recall now that, if $|K_S|$ has a nonempty fixed part $\Phi$ and we write $|K_S| = |M| + \Phi$, then, since $K_S$ is nef, $6 = K_S^2 = K_S \cdot \Phi + M \cdot \Phi + M^2 \geq M \cdot \Phi + M^2 \geq 2 + 4$, the last inequality following from the 2-connectedness of canonical divisors, and by the fact that the canonical system is not a pencil (as shown in [Hor3]).

Whence, if the fixed part $\Phi \neq \emptyset$ we have

$$M^2 = 4, M \cdot \Phi = 2, K_S \cdot \Phi = 0.$$  

Therefore we conclude that $K_X$ has no fixed part on the canonical model $X$, and only the following cases a priori occur:

- (0) $|K_X|$ is base point free
- (2) $|K_X|$ has 2 smooth base points
- $|K_X|$ has a smooth base point plus possibly an infinitely near one (these two cases are however shown by Horikawa not to occur)
- (1) $|K_X|$ has a singular base point $p$ on $X$.

The last case is the only one where there is a fixed part $\Phi$ on the minimal model. Since to the point $p \in \text{Sing}(X)$ corresponds the fundamental cycle $Z$ (pull back of the maximal ideal $\mathcal{M}_p \subset \mathcal{O}_{X,p}$), we have $\Phi \geq Z$. $Z$ has the property that for each divisor $\Psi$ which lies in the inverse image of $p$ one has $Z \cdot \Psi \leq 0$.

Write $\Phi = Z + \Psi$, and assume $\Psi > 0$. Observe then that $M \cdot \Phi = 2, K_S \cdot \Phi = 0$ implies $\Phi^2 = -2$. Then $-2 = \Phi^2 = Z^2 + 2Z \cdot \Psi + \Psi^2 \leq$
\(-2 + 0 - 2 = -4\) is a contradiction, whence \(\Phi\) equals the fundamental cycle.

Denote by \(Q\) the image of the canonical map and assume that it is a quadric cone.

Blowing up the base points of \(\phi_{K_X}\) we obtain a morphism \(f^0 : X^0 \to Q\), and let us observe that the irreducible exceptional curves of \(X^0 \to X\) are at most 2.

In any case the blow-up formula yields

1. \(K_{X^0} = \pi^*(K_X)\) in cases (0) and (1)
2. in case (2) there are two (-1)-curves \(E_1, E_2\) such that \(K_{X^0} - E_1 - E_2 = \pi^*(K_X)\).

Remark 1.1. In case (0) the canonical map \(\Phi_X\) is a finite morphism, whence (***) holds if and only if \(\text{Im}(\Phi_X)\) is a quadric cone, i.e., if and only if \(\Phi_X\) has degree 3 (as it is easy to see, cf. Lemma 4.1 of \cite{Hor3}).

In the other two cases we have \(\deg(\Phi_X) = 2\).

Remark 1.2. Assume that we are in cases (2), (1) and that the canonical image is a quadric cone \(Q\).

Let \(L', L^0, L''\) be the respective proper transforms on \(X\), resp. \(X^0\), resp. \(S\) of a general line \(l \subset Q\).

Observe that the canonical divisor \(K_X\) is the pull back of a hyperplane divisor on \(Q\), and its pull back to \(X^0\) has as movable part the pull back \(H\) of a hyperplane divisor on \(Q\).

Whence \(H \equiv 2L^0 + W\), where \(W\) is the effective divisor on \(X^0\) corresponding to the inverse image of the vertex \(v \in Q\).

More precisely, \(W\) is the fixed part of \(|H - 2L^0|\).

Assume that there is a Weil divisor \(L\) satisfying (***): then one immediately sees that \(h^0(X, L) = 2\) and there is an effective divisor \(E'\) on \(X\) with \(L \equiv L' + E'\), and where \(E'\) is the fixed part of the pencil \(|L|\). Then the fixed part of \(K_X - 2L'\) equals \(2E'\), whence \(\pi_*(W) = 2E'\).

It follows that (the linear equivalence class of) \(K_X \equiv 2L' + \pi_*(W)\) is 2-divisible as a Weil divisor if and only if \(\pi_*(W)\) is 2-divisible as an effective divisor.

There are two possibilities for this: \(f^{-1}(v)\) has dimension 0, or, in case where \(f^{-1}(v)\) has dimension 1, we have \(\pi_*f^{-1}(v) = 2E'\). In this last case, we have that \(f^0\) factors through the Segre-Hirzebruch surface \(\mathbb{F}_2\).

We recall now the case subdivision given by Horikawa (\cite{Hor3})

Definition 1.3. Assume we are in case (0) (\(K_X\) has no base points): then we have type (Ia) if \(\phi_{K_X}\) has degree 1, type (Ib) if \(\phi_{K_X}\) has degree 2, type (II) if \(\phi_{K_X}\) has degree 3.

Case (III) is the case where \(\phi_{K_X}\) has degree 2, but there is no genus 2 pencil on \(X\). There are two subcases: (IIIa), where the canonical image is a smooth quadric and we have two smooth base points, and...
(III_b), where the canonical image is a quadric cone and we have one singular base point.

The two cases of type (IVa-1), (IVa-2) have a smooth quadric as canonical image, the two cases of type (IVb-1), (IVb-2) have a quadric cone as canonical image, \( X^0 \) is a double cover of \( \mathbb{P}_2 \), but the section at infinity is not part of the branch locus.

Surfaces of type (IV) and (V) have all a genus 2 pencil. Surfaces of type (V-1) (V-2) have a quadric cone as canonical image, \( X^0 \) is a double cover of \( \mathbb{P}_2 \), and the section at infinity is part of the branch locus. For type (V-1) we are in case (2), for type (V-2) we are in case (1).

**Proposition 1.4.** The canonical model \( X \) of a surface with \( K^2 = 6, p_g = 4 \) satisfies condition (***)(there exists a Weil divisor \( L \) on \( X \) such that \( 2L \equiv K_X \) and \( h^0(X,L) \geq 2 \)) if and only if it is of one of the following types: (II), (III_b), (V-1) or (V-2).

**Proof.** Since the canonical image must be a quadric cone \( Q \), cases (Ia), (Ib), (III_a), (IVa-1), (IVa-2) are immediately excluded.

Assume that (*** holds for some surface of type (IVb-1) or (IVb-2). We know that the section at infinity \( \Delta_\infty \) is isolated in the branch locus, whence its set theoretic inverse image is a smooth \(-1\)-curve \( W_\infty \), thus \( f_0^{-1}(v) \) has dimension 0.

In cases (V-1), (V-2) again one shows that \( f_0^{-1}(v) \) has dimension 0, using Theorems 6.1, resp. 6.2, ibidem.

\( \square \)

2. SURFACES OF TYPE II AND III_b.

In this section we want to concentrate on the above classes of surfaces, the ones for which (*** holds, but there is no genus 2 pencil on \( S \).

The following lemma shows that the classes (II) and (III_b) are exactly those for which the pencil \( |L| \) has no fixed part.

**Lemma 2.1.** Assume that (*** holds and write \( K_S \equiv 2\Lambda + Z \) where \( K_S \cdot Z = 0 \). Then the pencil \( |L| \) is without fixed part (i.e., \( L' \equiv L \),
equivalently \( \Lambda \equiv L'' \) if and only if there is no genus 2 pencil on \( X \). In this case, the general element in \(|L''|\) is smooth irreducible of genus \( g(L'') = 3 \) and we have: \((L'')^2 = 1, L'' \cdot Z = 1\). It follows also that \( Z^2 = -2 \) and thus \( Z \) is the fundamental cycle of a singular point \( P_1 \) of \( X \).

**Proof.** Write \(|\Lambda| = |L''| + E''\) with \( E'' > 0 \). Since \( K_S \equiv 2L'' + 2E'' + Z \), we have \( L'' \cdot K_S + E'' \cdot K_S = 3 \), and moreover \( L'' \cdot K_S > 0, E'' \cdot K_S > 0 \).

It is impossible that \( L'' \cdot K_S = 1 \), since then \( L'' \) is odd, and \( L'' \cdot K_S \geq 2 \) (\( L'' \) is nef), a contradiction.

Thus \( L'' \cdot K_S = 2 \) and \( L''^2 = 0 \), thus we have a genus 2 pencil.

Conversely, the curves of a genus 2 pencil map to the lines of the quadric cone \( Q \), but if \(|L|\) is without fixed part then \( E'' = 0 \), and we claim that \( L'' = \Lambda \) is a pencil of genus 3 curves.

In fact, \( L''K_S = 3 = 2(L'')^2 + L'Z \), thus \( L''Z \) is odd. Since \( L''Z \) is non negative and odd, while \( L''K_S = 3 \) implies that \((L'')^2\) is also odd, the only possibility is that \((L'')^2 = 1, L''Z = 1\). Whence, \( p(L'') = 3 \).

In particular, \(|L''|\) has a unique smooth base point \( P_0 \) and the general curve in \(|L''|\) is smooth by Bertini’s theorem.

Since \( L''Z = 1 \), follows that \( Z^2 = -2 \), and since \( Z \) is the only divisor in \( 2L'' + Z \equiv K_S \) exceptional for \( S \rightarrow X \), follows that \( Z \) is a fundamental cycle.

\[ \square \]

**Definition 2.2.** Assume that (*** holds. Then the semicanonical ring of \( X \) is the graded ring

\[ B := \oplus_{m=0}^{\infty} B_m := \oplus_{m=0}^{\infty} H^0(X, mL). \]

**Remark 2.3.** Obviously,

\[ B_{2m} \cong H^0(X, mK_X) \cong H^0(S, mK_S), B_{2m+1} \cong H^0(S, mK_S + L''). \]

**Lemma 2.4.** Assume that \(|L|\) is without fixed part on \( X \). Then the sequence

\[ 0 \rightarrow H^0(S, \mathcal{O}(mK_S)) \rightarrow H^0(S, \mathcal{O}(mK_S + L'')) \rightarrow H^0(\omega_{L''}((m-1)K_S)) \rightarrow 0 \]

is exact. Moreover, \( \dim B_{2m} = 5 + 3m(m-1) \) for \( m \geq 2 \), \( \dim B_{2m+1} = 7 + 3(m + 1)(m - 1) \) for \( m \geq 1 \).

**Proof.** We have an exact sequence of sheaves given by the adjunction formula and moreover \( h^1(\mathcal{O}(mK_S)) = 0 \) for each \( m \) since \( g(S) = 0 \). The rest follows from the previous remark and from the fact that \( K_S \cdot L'' = 3 \) and a general \( L'' \) is smooth of genus 3.

\[ \square \]

**Lemma 2.5.** Consider a basis \( \{x_0, x_1\} \) of \( H^0(X, L) \) and pick \( y_2 \in H^0(X, 2L) \) in order to complete \( \{x_0^2, x_0x_1, x_1^2\} \) to a basis of \( H^0(X, 2L) \). Then \( \{x_0^3, x_0^2x_1, x_0x_1^2, x_1^3, x_0y_2, x_1y_2\} \) are linearly independent and there
exists an element $z_3 \in H^0(X, 3L)$ completing the previous set to a basis of $H^0(X, 3L)$.

**Proof.**

Otherwise, w.l.o.g. we may assume that we have a relation of the form

$$x_0 y_2 = G_3(x_0, x_1)$$

where $G$ is homogeneous of degree 3 and divisible by $x_1$.

But then, setting $y_{00} := x_0^2, y_{11} := x_1^2, y_{01} := x_0 x_1$, we have $G_3(x_0, x_1) = x_1 L(y_{00}, y_{11}, y_{01}, y_2)$ where $L$ is a linear form. Whence, the canonical image of $X$ satisfies 3 quadratic equations

$$y_{00} y_{11} = y_{01}^2, y_{00} y_2 = y_{01} L(y), y_{01} y_2 = y_{11} L(y).$$

But it is shown by Horikawa (Hor3) that $|K_S|$ is not a pencil.

There remains only to observe that $h^0(X, 3L) = 7$, by the previous lemma.

□

**Lemma 2.6.** Assume that $|L|$ is without fixed part on $X$. The following three conditions are equivalent:

- $X$ is of type (II), i.e., the canonical map has degree 3
- the general curve in $|L''|$ is non hyperelliptic
- the sections $x_0, x_1, y_2, z_3$ provide a morphism $\psi$ to the 3-dimensional weighted projective space $\mathbb{P}(1, 1, 2, 3)$ which is birational onto a hypersurface $\Sigma$ of degree 9.

In case (IIIb) we have:

- every curve in $|L''|$ is hyperelliptic,
- the base point $P_0$ of $|L''|$ is a Weierstraß point of every curve $L''$
- $Z$ is the fixed part of $K_S$
- the canonical map is a double covering of a quadric cone.

**Proof.** Since $|L''|$ has a simple base point $P_0$ the general curve in the pencil is smooth of genus 3 and its canonical system has no base points. Whence $|3L'' + Z| = |K_S + L''|$ has no base points on the general curve $L''$, and in particular $P_0$ is not a base point; thus the base points are contained in $Z$. Whence on $X$ the only possible base point (where $x_0 = x_1 = z_3 = 0$) is $P_1$.

We observe that there is a base point of $\psi$ if and only if $y_2$ vanishes on $P_1$, and this case will be denoted by (*).

In case (*) $P_1$ is a point where $x_0 = x_1 = y_2 = 0$, whence $Z$ is in the fixed part of the canonical system, but $|K_S - Z| = |2L''|$ has no base point since $(K_S - Z)^2 = 4$ and its base locus is $\subset \{P_0\}$. Hence, $|K_S - Z|$ yields a morphism $f : X \to \mathbb{P}^3$ which is a double cover of the quadric cone, and $P_1$ is the unique point where $x_0 = x_1 = y_2 = 0$, and $Z$ is exactly the fixed part of the canonical system.
In general, by lemma 2.3 follows that \( \psi \) is birational if and only if the general curve in \( |L'| \) is non-hyperelliptic, and in any case the degree of \( \psi \) is at most 2.

If we are not in case (*), we simply observe that \( \psi \) is then a morphism and that \( \deg(\psi)\deg(\Sigma) = 9 = 6(3/2) \), but we have already seen that if the map is not birational, its degree is 2.

Whence, it follows that \( \psi \) is a birational morphism (and obviously then \( \deg(\Sigma) = 9 \)).

In case (*) every curve in \( |L'| \) is a double cover of a line, whence all the curves in \( |L'| \) are hyperelliptic. Since the point \( P_0 \) is invariant by the involution of \( S \) yielding the hyperelliptic involution on every curve in \( |L'| \), it follows that \( P_0 \) is a Weierstraß point.

More precisely, the exact sequence

\[
0 \to O_S(L'' + Z) \to O_S(K_S) \to O_{L''}(K_S) \to 0
\]

and the remark that \( O_{L''}(K_S) = \omega_{L''}(-P_0) \) shows that \( |K_S| \) has \( P_0 \) as a base point on \( L'' \) if and only if \( L'' \) is hyperelliptic and \( P_0 \) is a Weierstraß point.

\[\square\]

Horikawa gave a very concrete description of surfaces of type (IIIb).

**Theorem 2.7 (5.2 in \[Hor3\]).** Let \( S \) be a surface of type IIIb. Then \( S \) is birationally equivalent to a double covering of \( \mathbb{P}^2 \) whose branch locus \( B \) consists of the negative section \( \Delta_\infty \) and of \( B_0 \in |7\Delta_\infty + 14\Gamma| \) which has a quadruple point \( x \) and a \((3,3)\)-point at \( y \) such that \( x \) and \( y \) belong to the same fibre \( \Gamma_0 \in |\Gamma| \). Moreover, \( y \) may be infinitely near to \( x \).

3. **On rings associated to curves of genus 3**

To compute the semi-canonical ring we use ideas related to the hyperplane section principle introduced by Miles Reid (cf. page 218 of \[Rei2\]).

**The hyperplane section principle:** Let \( B \) be a graded ring, and \( x_0 \in B \) a homogeneous non-zero divisor of degree \( \deg x_0 > 0 \); set \( \overline{B} = B/(x_0) \). The hyperplane section principle says that quite generally, the generators, relations and syzygies of \( B \) reduce mod \( x_0 \) to those of \( \overline{B} \).

**Proposition 3.1.** Let \( B \) be the semicanonical ring of \( X \) and fix an element \( x_0 \) of degree 1 in \( B \) whose divisor yields a smooth curve \( C \in |L'| \). Then the quotient ring \( \overline{B} = B/(x_0) \) satisfies

\[
\overline{B}_{2m+1} = H^0(\omega_{L''}((m-1)K_S)), \quad \overline{B}_{2m} = H^0(O_{L''}(mK_S)).
\]

**Proof.** The first assertion follows immediately from lemma 2.4. The second assertion is immediately verified for \( m = 1 \), while, for \( m \geq 2 \), it
follows from the exact sequence
\[ 0 \to H^0(S, \mathcal{O}(mK_S - L'')) \to H^0(S, \mathcal{O}(mK_S)) \to H^0(\mathcal{O}_{L''}(mK_S)) \to \]
\[ \to H^1(S, \mathcal{O}(mK_S - L'')) \to 0 \]
and the vanishing of
\[ h^1(S, \mathcal{O}(mK_S - L'')) = h^1(S, \mathcal{O}(-(m - 2)K_S + L'' + Z)) \]

Here we use Serre duality plus the fact that, on a regular surface \((q = 0)\)
\[ H^1(S, \mathcal{O}(-D)) = 0 \text{ if the divisor } D \text{ is effective and numerically connected} \]
(cf. [Bom]). That \((m - 2)K_S + L'' + Z\) is numerically connected can be proved directly, but follows more easily for case (IIIb) when we observe that by Theorem 5.2 of [Hor3], \(Z\) is an irreducible \(2\)-curve.

\[\square\]

Let us compute the ring \(\mathcal{B}\) for surfaces of type IIIb.

We see immediately from the previous proposition, and from lemma 2.6 that the quotient ring \(\mathcal{B}\) is isomorphic to a ring of the type described in the following

**Definition 3.2.** Let \(C\) be a smooth hyperelliptic curve of genus 3, \(p \in C\) be a Weierstraß point, and \(X\) a section of \(H^0(\mathcal{O}_C(p))\) with \(\text{div}(X) = p\).

Consider the Itaka ring \(R(C, p) := \bigoplus_{d \geq 0} H^0(\mathcal{O}_C(p)^{\otimes d})\) and define \(R(C, \frac{3}{2}p)\) as the graded subring with
\[
\begin{cases}
R(C, \frac{3}{2}p)_{2d} := R(C, p)_{3d} \\
R(C, \frac{3}{2}p)_{2d+1} := R(C, p)_{3d+1}
\end{cases}
\]
and with product defined, for homogeneous elements, as \(ab = a \otimes b\), resp. \(a \otimes b \otimes X\) according to the parity of the product of the degrees of \(a\) and \(b\) (even, resp. odd).

So, the ring \(\mathcal{B}\) for surfaces of type IIIb being a subring of \(R(C, p)\), we need first to describe the latter.

The ring of a Weierstraß point of a smooth hyperelliptic curve is well known in every genus: for the convenience of the reader we state and prove here the result in the case of genus 3.

**Lemma 3.3.** Let \(C\) be a hyperelliptic curve of genus 3, \(p \in C\) a Weierstraß point: then \(R(C, p) \cong \mathbb{C}[X, Y, T]/(T^2 - P_{14}(X, Y))\) where \(\deg(X, Y, T) = (1, 2, 7)\) and \(P_{14}\) is homogeneous of degree 14.

**Proof.** Let \(X\) be a section of \(H^0(\mathcal{O}_C(p))\) with \(\text{div}(X) = p\): the section \(X\) is antiinvariant and the divisor \(p\) is invariant under the hyperelliptic involution \(\sigma\), such that \(\phi : C \to C/\sigma \cong \mathbb{P}^1\) is branched on a divisor \(B\) of degree 8.

The morphism \(\phi\) is given by a basis of \(H^0(\mathcal{O}_C(2p))\), for instance let us take \(X^2\) and a new element \(Y\).
We have $\phi_*\mathcal{O}_C = \mathcal{O}_{\mathbb{P}^1} \oplus Z\mathcal{O}_{\mathbb{P}^1}(-4)$, where $Z$ is an equation for the ramification divisor of $\phi$.

The even part of our ring is thus $\oplus_{m=0}^{\infty} H^0(\phi_*\mathcal{O}_C(m)) = \mathbb{C}[X^2, Y] \oplus Z\mathbb{C}[X^2, Y]$.

Since $Z \in H^0(\mathcal{O}_C(8p))$, and $X$ divides $Z$, we may write $Z = XT, T \in H^0(\mathcal{O}_C(7p))$.

Observe that $X, Z$ being antiinvariant, then $T$ is invariant.

Consider now $H^0(\mathcal{O}_C((2m+1)p))$: this space splits as the direct sum of the $(+1)$, respectively $(-1)$-eigenspace. By looking at the behaviour at the ramification points, we see immediately that the sections of $H^0(\mathcal{O}_C((2m+1)p))$ are divisible by $T$, the ones of $H^0(\mathcal{O}_C((2m+1)p))$ are divisible by $X$, thus the odd part of our ring is $T\mathbb{C}[X^2, Y] \oplus X\mathbb{C}[X^2, Y]$. It follows that our ring is $\mathbb{C}[X, Y] \oplus T\mathbb{C}[X, Y]$.

Its ring structure is easily obtained when we observe that $T^2$ is the pull back of the equation of the seven remaining branch points: thus we have a relation of the form $T^2 = P_{14}(X, Y)$ and our claim is proven.

\[\square\]

**Proposition 3.4.** Let $C$ be a hyperelliptic curve of genus 3, $p \in C$ be a Weierstraß point. Then $R(C, 3^2p) \cong \mathbb{C}[x, y, z, w, v, u]/I$, where $\deg(x, y, z, w, v, u) = (1, 2, 3, 4, 5, 6)$ and the ideal $I$ is generated by the 4 $\times$ 4 pfaffians of the skew-symmetric 'extra-symmetric' matrix

\[M = \begin{pmatrix}
0 & 0 & z & v & y & x \\
0 & w & u & z & y & 0 \\
0 & \tilde{P}_9 & u & v & 0 & w^2 \cdot zw \\
-sym & 0 & 0 & 0 & 0 & 0
\end{pmatrix},\]

where $\tilde{P}_9$ is a homogeneous polynomial of degree 9 in the variables $x, y, z, w$.

**Proof.**

It is easy to verify that the following 6 elements

\[
x = X \quad y = XY \quad z = Y^2 \quad w = Y^3 \quad v = T \quad u = YT;
\]

generate $R(C, 3^2p)$; note that by definition the 2 $\times$ 2 minors of the matrix

\[\begin{pmatrix}
x & y & z & v \\
y & z & w & u
\end{pmatrix}
\]

belong to the ideal $I$ of relations.

The other relations for these generators come from the equation $T^2 - P_{14}$; we note that the coefficient of $Y^7$ in the polynomial $P_{14}$ of lemma
cannot vanish (or the 8 branch points of the hyperelliptic map \( \phi \) would not be distinct), and therefore we can assume w.l.o.g. that this coefficient be 1. We write then the relation as \( T^2 - Y^7 - X P_{13} \). Let \( \tilde{P}_9 \) be a homogeneous polynomial of degree 9 in the variables \((x, y, z, w)\) such that \( \tilde{P}_9(X, XY, Y^2, Y^3) = P_{13}(X, Y) \) (the reader can easily check that it exists and is uniquely determined modulo the \( 2 \times 2 \) minors of the matrix \( \Pi \)).

The relation \( T^2 - P_{14} \) is a relation in degree 14 in \( R(C, p) \), and \( R(C, p)_{14} \) is not contained in the subring \( R(C, \frac{3}{2}p) \): but multiplying it by suitable monomials we obtain the following relations

\[
\begin{align*}
XT^2 & - XY^7 - X^2 P_{13}(X, Y) \quad \text{in degree 15} \\
YT^2 & - Y^8 - YX P_{13}(X, Y) \quad \text{in degree 16} \\
Y^2 T^2 & - Y^9 - XY^2 P_{13}(X, Y) \quad \text{in degree 18},
\end{align*}
\]

which can be rewritten as polynomials in the variables \( x, y, z, w, v, u \) (uniquely determined modulo the \( 2 \times 2 \) minors of \( \Pi \)) as

\[
\begin{align*}
v^2 & - z^2 w - x \tilde{P}_9 \quad \text{in degree 10} \\
v u & - zw^2 - y \tilde{P}_9 \quad \text{in degree 11} \\
v^2 & - w^3 - z \tilde{P}_9 \quad \text{in degree 12}.
\end{align*}
\]

The reader can immediately check that the ideal \( I \) generated by these three last equations and the \( 2 \times 2 \) minors of \( \Pi \) coincides with the ideal of the \( 4 \times 4 \) pfaffians of the matrix in the statement.

There are no other relations since one can easily check that the Hilbert function of \( R(C, \frac{3}{2}p) \) coincides with the one of \( \mathbb{C}[x, y, z, w, v, u]/I \). \( \square \)

4. The family of deformations

The hyperplane section principle gives a strategy in order to reconstruct the ring \( B \) for every surface of type \( III_b \): taken \( C \) a smooth element of the pencil \( |L''| \) and \( x_0 \) a corresponding section the 'hyperplane section' quotient \( B = B/(x_0) \) equals the ring \( R(C, \frac{3}{2}p) \) in proposition 3.4.

\( B \) is obtained from \( R(C, \frac{3}{2}p) \) by adding the generator \( x_0 \) and deforming the 9 equations adding suitable multiples of \( x_0 \) in such a way that all the syzygies also deform.

To compute all possible 'extensions' as above is in general very difficult. For these problems it is in general useful to use a 'flexible format' (i.e., with free parameters) as the one we are going to recall.

The extra-symmetric format. Let \( A \) be a polynomial ring.
A skew-symmetric matrix $M$ is said to be extra-symmetric if it has the form
\[
\begin{pmatrix}
0 & a & b & c & d & e \\
0 & f & g & h & d \\
0 & i & pg & pc \\
0 & qf & qb \\
-sym & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]
for suitable elements $a, b, c, d, e, f, g, h, i, p, q \in A$. Then the ideal of the fifteen $4 \times 4$ pfaffians is generated by 9 of them; moreover, if the entries are general enough, this pfaffian ideal has exactly 16 independent syzygies, which can all be explicitly written as functions of the entries of the matrix (the computation is done in [Rei2] in a slightly more special case, and it extends to this more general case).

This implies that, if we have a ring that can be written in this form, and the ring has no further syzygies (except the 16 we know), deforming the entries of the matrix (preserving the symmetries) we get at the same time a deformation of the ideal and a deformation of the syzygies (i.e. a flat deformation).

The first example of a ring presented through the $4 \times 4$ pfaffians of a skew-symmetric extra-symmetric matrix was produced by D. Dicks and M. Reid ([Rei1]). This more general form appeared in [Rei3]; see also [BCP] for another application of it.

In lemma 3.4 we wrote the ring $R(C, \frac{3}{2}p) = \overline{B}$ in extra-symmetric format; therefore, if we add a variable $x_0$ in degree 1 and lift $M$ to a matrix $N$ that is still skew-symmetric and extra-symmetric, its pfaffians should define a surface of type $III_b$.

Note that, since the format is not complete, the family which we write can be (and in fact is) smaller than the whole family of surfaces of type $III_b$.

We add then the variable $x_0$ and rename the old variable $x$ by $x_1$.

**Theorem 4.1.** Consider the ring $\mathbb{C}[x_0, x_1, y, z, w, v, u]$ with variables of respective degrees $(1, 1, 2, 3, 4, 5, 6)$.

Consider a skew-symmetric extra-symmetric matrix
\[
M' = \begin{pmatrix}
0 & 0 & z & v & y & x_1 \\
0 & w & u & P_3 & y \\
0 & P_9 & u & v \\
0 & wP_4 & zP_4 \\
-sym & 0 & 0 \\
0 & 0
\end{pmatrix}
\]
where the $P_i$’s are homogeneous polynomials of degree $i$ in the first 5 variables of the ring, and let $J$ be the ideal generated by the $4 \times 4$ pfaffians of $M$. 

Then, for general choice of the polynomials $P_i, \mathbb{C}[x_0, x_1, y, z, w, v, u]/J$ is the semi-canonical ring of a surface of type III$_b$: we obtain in this way a family of codimension 2 (and therefore of dimension 36) in the stratum of the moduli space of surfaces with $p_g = 4, K^2 = 6$ corresponding to surfaces of type III$_b$.

**Proof.** $J$ defines a subvariety $X$ in $\mathbb{P}(1, 2, 3, 4, 5, 6)$.

We first show that, for general choice of the entries of $M'$, $X$ has only rational double points as singularities.

We denote by $V$ the 3-fold (containing $X$) defined by the $2 \times 2$ minors of the submatrix of $M' B = (z v y x_1, w u P_3, y)$.

Since the condition of having rational double points is well known to be open, we may assume w.l.o.g. $P_3 = z$. Note that, by row and column operations on $B$ and analogously on $M'$, one can replace $P_3$ by a linear combination of $z$ and $x_0^3$ (we are thus working on a subfamily of codimension at most 1).

$V$ is a cone over a quasi smooth scroll in $\mathbb{P}(1, 2, 3, 4, 5, 6)$: it is therefore quasi smooth outside the vertex $p_0 := (1, 0, 0, 0, 0, 0, 0)$.

$X$ is defined in $V$ by the remaining 3 equations

$$v^2 = z^2 P_4 + x_1 P_9, \quad vu = zw P_4 + y P_9, \quad u^2 = w^2 P_4 + z P_9.$$  

The three above equations describe (as we vary $P_4$ and $P_9$) an open set of a linear system of divisors on $V$ without base points; by Bertini’s theorem, for general choice of the coefficients of $P_4$ and $P_9$ the surface $X$ is quasi smooth outside the point $p_0$. To take care of possible singularities outside $p_0$ we have to intersect $X$ with the singular locus of $\mathbb{P}(1, 1, 2, 3, 4, 5, 6)$.

A singular point of $\mathbb{P}(1, 1, 2, 3, 4, 5, 6)$ has $x_0 = x_1 = 0$: under these assumptions the equations of $V$ easily force $y = z = 0$, and consequently by the first of the above further three equations we get the vanishing of the coordinate $v$.

We are left with at most two nonzero coordinates, $u$ and $w$, but consider the last equation ($u^2 = \ldots$): for general $P_4$ we have (up to a rescaling) $P_4 = w + \ldots$, thus we get only one point, exactly the point $(0, 0, 0, 0, 1, 0, 1)$.

This point is in fact a singular point of the ambient space, since the $\mathbb{C}^*$ action has in the corresponding point in $\mathbb{C}^7$ a non trivial stabilizer $\cong \mathbb{Z}/2\mathbb{Z}$. Therefore in this point $X$ has an isolated singularity locally isomorphic to the quotient of a smooth surface by a $\mathbb{Z}/2\mathbb{Z}$ action: in other words, a singular point of type $A_1$. 

THE MODULI SPACE OF SURFACES WITH $K^2 = 6$ AND $p_g = 4$.

We are left with the vertex $p_0$ of the cone $V$. This point is smooth for the ambient space $\mathbb{P}(1, 1, 2, 3, 4, 5, 6)$: we set $\{x_0 = 1\}$ and work in affine coordinates.

For general choice of the coefficients $P_9$ is invertible at $p_0$: since all other entries of $M$ do vanish in $p_0$ we get that all equations vanish in $p_0$ and only the pfaffians including $P_9$ are smooth in it.

We get that the Zariski tangent space of $X$ at $p_0$ has dimension 3, and more precisely it is $\{x_1 = y = z = 0\}$. We eliminate then (we have set $\{x_0 = 1\}$) $x_1$, $y$ and $z$. We obtain the equation $wv = P_9^{-1}u(u^2 - w^2 P_4)$: a rational double point of type $A_2$.

We have thus shown that, for general choice of the coefficients, $X$ has only rational double points as singularities.

The projection from $V$ to the quadric cone $\mathbb{P}(1, 1, 2)$ given by the first three variables $x_0, x_1, y$ has $\mathbb{P}^1$ as general fibre: for $x_1 \neq 0$ the equations of $V$ can be explicitly solved, and yield $z = y^2/x_1$, $w = y^3/x_1^2$.

The remaining 3 equations cut clearly two points on the general $\mathbb{P}^1$ fibre of the projection to $\mathbb{P}(1, 1, 2)$: therefore the induced map $X \to \mathbb{P}(1, 1, 2)$ has degree 2.

We have the following recipe to obtain the branch curve:

- start with the polynomial $z^2 P_4 + x_1 P_9$;
- substitute $z \mapsto y^2/x_1$;
- substitute $w \mapsto y^3/x_1^2$;
- multiply the result by $x_1^4$.

What we get is a polynomial (in fact in the last step we get rid of the denominators) of degree 14 in the variables $x_0, x_1, y$ (remember that we have assumed $v, u$ not to appear in $P_9$), therefore the branch curve is a general curve of degree 14 in $\mathbb{P}(1, 1, 2)$ contained in the ideal $(y^7, x_1 y^6, x_1^2 y^4, x_1^3 y^3, x_1^4 y^2, x_1^5)$; these curves form a linear system on $\mathbb{P}(1, 1, 2)$ with base point $(1, 0, 0)$. Its general element has a 5–ple point in $(1, 0, 0)$ and is smooth elsewhere.

We blow up the point $(1, 0, 0)$, take the complete transform and remove 4 times the exceptional divisor. Then we get a triple point with tangent cone three times the direction of the exceptional divisor.

Blowing up again and removing the new exceptional divisor twice from the complete transform of the branch curve, we then obtain a 4-ple point with (in general) three different tangent directions: after a last blow up we remain with at most non essential singularities.

Summarizing, our branch curve of degree 14 has a 5–tuple point in $(1, 0, 0)$ with an infinitely near $(3, 3)$-point; by [Hor3], thm. 5.2., the desingularisation of $X$ is a surface of type $(III_b)$.

In order to count the number of moduli of this subfamily of surfaces of type $(III_b)$, we observe that the two singular points are infinitely near (one condition), the 'infinitely near' triple point is in the direction of the exceptional divisor (one condition).
Moreover, we have the further condition that the coefficient of the monomial $yx^4$ (in the equation of the branch curve) vanishes: in fact a straightforward computation shows that the two first conditions force the equation of the branch curve to be only in the ideal
\[(y^7, x_1 y^6, x_1^2 y^4, x_1^3 y^3, x_1^4 y^2, y x_4^4, x_5^5).\]

Under the assumption that $P_3 = z$, we have a $38 - 3 = 35$ dimensional family of surfaces of type $\text{III}_b$; in general we have to write $P_3 = z + \lambda x_0^3$; the projection on $\mathbb{P}(1, 1, 2)$ has clearly still degree 2 and we have a similar recipe for computing the branch curve. We still have a curve as described in theorem 2.7, still the two base points are infinitely near, but the singular point can have multiplicity 4 (instead of 5), so are not in the subfamily and the dimension of the whole family is one more, i.e., 36.

\[\square\]

Remark 4.2. It is clear from the previous proof that the above family given by the pfaffians of $M'$ (having dimension 36) (cf. 4.1) is a proper subfamily of the 37 - dimensional family of surfaces of type $\text{III}_b$, such that the two essential singularities of the branch curve of the canonical double cover are infinitely near. (cf. [Hor3]). We do not have any geometric characterization for this subfamily.

Theorem 4.3. Let $(x_0, x_1, y, z, w, v, u)$ be variables of respective degrees $(1, 1, 2, 3, 4, 5, 6)$, Let $M$ be the $6 \times 6$ skew-symmetric matrix

\[
M = \begin{pmatrix}
0 & t & z & v & y & x_1 \\
0 & w & u & P_3 & y & \\
0 & P_9 & u & v & \\
0 & w P_4 & z P_4 & \\
-sym & 0 & t P_4 & 0 & \\
\end{pmatrix}.
\]

where the $P_i$'s are homogeneous polynomials of degree $i$ in the above variables and $t$ is the parameter on a small disk $\Delta \subset \mathbb{C}$.

For general choice of $P_3, P_4$ and $P_9$ the $4 \times 4$ pfaffians of $M$ define a variety $X \subset \Delta \times \mathbb{P}(1, 1, 2, 3, 4, 5, 6)$ whose projection on $\Delta$ is flat, with central fibre a surface of type $\text{III}_b$ and with general fibre a surface of type $\text{II}$.

Proof. The flatness of the above family (for general entries) follows directly from the flexibility of the format. For $t = 0$ the above matrix equals the matrix $M'$ in thm. 4.1.

Assume now that $t \neq 0$.

Note that the pfaffians $Pf_{1235}$ and $Pf_{1236}$ are of the form $tu - \cdots$ and $tv - \cdots$, and that for a general choice of $P_4$, the pfaffian $Pf_{1256}$ can be written as $t^2 w - \cdots$. Therefore, for $t \neq 0$, we can eliminate the variables $u, v, w$, and $R \cong \mathbb{C}[x_0, x_1, y, z]/J$ for a suitable ideal $J$; a straightforward calculation shows that $J$ is a principal ideal generated
by the equation obtained from $P_{f_{1345}}$ after eliminating the variables $u, v, w$ using $P_{f_{1235}}, P_{f_{1236}}$ and $P_{f_{1256}}$.

This is a polynomial of degree 9, so the surface is birational to a hypersurface of degree 9 in $\mathbb{P}(1, 1, 2, 3)$, whence we obtain a surface of type $II$.

Our main theorem (0.1) follows right away from the above.
