On minimal factorizations of words as products of palindromes

May 3, 2014

Abstract

Given a finite word $u$, we define its palindromic length $|u|_{\text{pal}}$ to be the least number $n$ such that $u = v_1v_2\ldots v_n$ with each $v_i$ a palindrome. We address the following open question: Does there exist an infinite non ultimately periodic word $w$ and a positive integer $P$ such that $|u|_{\text{pal}} \leq P$ for each factor $u$ of $w$? In this note we give a partial answer to this question. Let $k$ be a positive integer. We prove that if an infinite word $w$ is $k$-power free, then for each positive integer $P$ there exists a factor $u$ of $w$ whose palindromic length $|u|_{\text{pal}} > P$. We also extend this result to a wider class of words satisfying the so-called $(k, l)$-condition, which includes for example the Sierpinski word.

1 Introduction

Let $A$ be a finite non-empty set, and let $A^+$ denote the set of all finite non-empty words in $A$. A word $u = u_1u_2\ldots u_n \in A^+$ is called a palindrome if $u_i = u_{n-i+1}$ for each $i = 1, \ldots, n - 1$. In particular each $a \in A$ is a palindrome. We also regard the empty word as a palindrome.

Palindrome factors of finite or infinite words have been studied from different points of view. In particular, Droubay, Justin and Pirillo \cite{Droubay} proved that a word of length $n$ can contain at most $n+1$ distinct palindromes, which gave rise to the theory of rich words. The number of palindromes of a given length occurring in an infinite word is called its palindrome complexity and is bounded by a function of its usual subword complexity \cite{Rich}. However, in this paper we study palindromes in an infinite word from the point of view of decompositions.

For each word $u \in A^+$ we define its palindromic length, denoted by $|u|_{\text{pal}}$, to be the least number $P$ such that $u = v_1v_2\ldots v_P$ with each $v_i$ a palindrome. As each letter is a palindrome, we have $|u|_{\text{pal}} \leq |u|$, where $|u|$ denotes the length of $u$. For example, $|01001010010|_{\text{pal}} = 1$ while $|010011|_{\text{pal}} = 3$. Note that 010011 may be expressed as a product of 3 palindromes in two different ways: $(0)(1001)(1)$ and $(010)(0)(11)$. In \cite{Ravsky}, O. Ravsky obtains an intriguing formula for the supremum of the palindromic lengths of all binary words of length $n$.

The question considered in this paper is

**Question 1** Does there exist an infinite non ultimately periodic word $w$ and a positive integer $P$ such that $|u|_{\text{pal}} \leq P$ for each factor $u$ of $w$?

We conjecture that such aperiodic words do not exist, but at the moment we can prove it only partially. Namely, in this paper we prove that if such a word exists, then it is not $k$-power-free for any $k$ and moreover, for all $k > 1$, $l \geq 0$ it does not satisfy the $(k,l)$-condition defined in Section 1. A discussion what exactly the condition means and which class of words should be studied now to give a complete answer to the question is given in Section 5.

A preliminary version of this paper has been reported at Journées Montoises 2012.

2 The case of $k$-power-free words

Let $k$ be a positive integer. A word $v \in A^+$ is called a $k$-power if $v = u^k$ for some word $u \in A^+$. An infinite word $w = w_1w_2 \ldots \in A^\mathbb{N}$ is said to be $k$-power-free if no factor $u$ of $w$ is a $k$-power. For instance, the Thue-Morse word $0110100110010110 \ldots$ fixed by the morphism $0 \mapsto 01, 1 \mapsto 10$ is 3-power free [6].

**Theorem 1** Let $k$ be a positive integer and $w = w_1w_2 \ldots \in A^\mathbb{N}$. If $w$ is $k$-power free, then for each positive integer $P$ there exist a prefix $u$ of $w$ with $|u|_\text{pal} > P$.

Recall that a word $u_1 \cdots u_n$ is called $t$-periodic if $u_i = u_{i+t}$ for all $1 \leq i \leq n-t$.

The proof of Theorem 1 will make use of the following lemmas.

**Lemma 2** Let $u$ be a palindrome. Then for every palindromic proper prefix $v$ of $u$, we have that $u$ is $(|u| - |v|)$-periodic.

**Proof.** If $u$ and $v$ are palindromes with $v$ a proper prefix of $u$, then $v$ is also a suffix of $u$ and hence $u$ is $(|u| - |v|)$-periodic. \(\square\)

In what follows, the notation $w[i..j]$ can mean the factor $w_i w_{i+1} \cdots w_j$ of a word $w = w_1 \cdots w_n \cdots$ as well as its precise occurrence starting with the position numbered $i$; we always specify it when necessary.

**Lemma 3** Suppose the infinite word $w$ is $k$-power-free. If $w[i_1..i_2]$ and $w[i_1..i_3]$ are palindromes with $i_3 > i_2$, then

\[
\frac{|w[i_1..i_3]|}{|w[i_1..i_2]|} > 1 + \frac{1}{k - 1}. \square
\]

**Proof.** By Lemma 2 the word $w[i_1..i_3]$ is $(i_3 - i_2)$-periodic; at the same time, it cannot contain a $k$-power, so, $|w[i_1..i_3]| < k(i_3 - i_2)$. Thus,

\[
\frac{|w[i_1..i_3]|}{|w[i_1..i_2]|} = \frac{|w[i_1..i_3]|}{|w[i_1..i_3]| - (i_3 - i_2)} > \frac{|w[i_1..i_3]|}{(1 - \frac{1}{k})(|w[i_1..i_3]|)} = 1 + \frac{1}{k - 1}. \square
\]

**Lemma 4** Let $N$ be a positive integer. Then for each $i \geq 0$, the number of palindromes of the form $w[i..j]$ of length less or equal to $N$ is at most $2 + \log_{k/(k-1)} N$.

**Proof.** For each $i \geq 0$, the length of the shortest non-empty palindrome beginning in position $i$ is equal to 1. By the previous lemma, the next palindrome beginning in position $i$ is of length more than $\frac{k}{k-1}$, and the one after that is of length more than $(\frac{k}{k-1})^2$, and so on. The longest one is of length at most $N$ but more than $(\frac{k}{k-1})^P$, so that $P \leq \log_{k/(k-1)} N$, and the total number $n + 1$ of such words is at most $1 + \log_{k/(k-1)} N$. Adding the empty word which is a palindrome gives the desired result. \(\square\)
PROOF OF THEOREM 4. Fix a positive integer \( P \) and let \( N \) be a positive integer satisfying
\[
(2 + \log_{k/(k-1)} N)^P < N.
\]
By the previous lemma, the number of prefixes of \( w \) of the form \( v_1 v_2 \ldots v_P \), where each \( v_i \) is a palindrome, of length less or equal to \( N \) is at most \( (2 + \log_{k/(k-1)} N)^P \), and hence at most \( N \). But \( w \) has \( N \)-many non-empty prefixes of length less or equal to \( N \). This means that there exists a prefix \( u \) of \( w \) of length less or equal to \( N \) such that \( |u|_{\text{pal}} > P \). \( \square \)

3 Privileged words and other regularities

In fact, the proof above does not use directly any properties of palindromes except for Lemma 3. So, analogous statements on the properties of \( k \)-power-free words can be proved for any other type of word regularities for which lemmas analogous to Lemma 3 hold. In particular, we can almost immediately extend Theorem 1 to privileged words.

Privileged words have been introduced by J. Kellendonk, D. Lenz and J. Savinien [5]; they are studied also in [8]. Privileged words are defined recursively as follows: first, the empty word and each element \( a \in A \) is privileged. Next, a word \( u \in A^+ \) with \( |u| \geq 2 \) is privileged if and only if it is a complete first return to a shorter non-empty privileged word, i.e., if there exists a non-empty privileged word \( v \) which is both a proper prefix and a proper suffix of \( u \) and which occurs in \( u \) exactly twice. For example, 00 is privileged as it is a complete first return to the privileged word 0. Similarly, 00101100 is privileged as it is a complete first return to the privileged word 00. This latter example shows that a privileged word need not be a palindrome. Conversely, the palindromes 123121 and 00101100110100 are not privileged as neither word is a complete first return. However, if a word \( w \) is rich meaning that it contains \( |w| + 1 \) factors which are palindromes, then each non-empty factor of \( w \) is a palindrone if and only if it is privileged (see Proposition 2.3 in [5]). Thus analogously we define the privileged length of a word \( u \in A^+ \), denoted \( |u|_{\text{priv}} \), to be the least number \( n \) such that \( u = v_1 v_2 \cdots v_n \) with each \( v_i \) a privileged word. Again we have the inequality \( |u|_{\text{priv}} \leq |u| \). For instance, \( |00101100|_{\text{priv}} = 1 \), while \( |00101100110100|_{\text{priv}} = 3 \). We note that 00101100110100 may be written as a product of 3 privileged words in more than one way: \( (0)(010110011010)(0) \) or \( (00)(101100110100)(0) \).

The following lemma is analogous to Lemma 2.

Lemma 5 Let \( u \) be a privileged word. Then for every privileged proper prefix \( v \) of \( u \), we have that \( u \) is \((|u| - |v|)\)-periodic.

PROOF. Suppose \( u \) and \( v \) are privileged words with \( v \) a proper prefix of \( u \). We will prove that \( v \) is also a suffix of \( u \). We proceed by induction on \(|u| \). The result is vacuously true for \(|u| = 1 \). Next suppose \(|u| > 1 \). Then \( u \) is a complete first return to a privileged word \( u' \) with \(|u'| < |u| \).

We claim that \(|v| \leq |u'| \). In fact, suppose to the contrary that \(|v| > |u'| \). Then \( u' \) would be a proper prefix of \( v \) and hence by induction hypothesis \( u' \) is also a suffix of \( v \). This means that \( u' \) occurs at least three times within \( u \) (as a prefix of \( v \), as a suffix of \( v \) and as a suffix of \( u \)). This contradicts that \( u \) is a complete first return to \( u' \). Having established that \(|v| \leq |u'| \), it follows that \( v \) is a suffix of \( u' \). In fact, if \(|v| = |u'| \), then \( v = u' \) while if \(|v| < |u'| \), then by induction hypothesis \( v \) is a suffix of \( u' \). As \( u' \) is a suffix of \( u \) we obtain that \( v \) is a suffix of \( u \) as required. Whence, \( u \) is \((|u| - |v|)\)-periodic. \( \square \)

Now using Lemma 5 we can prove the following lemma.

Lemma 6 Suppose the infinite word \( w \) is \( k \)-power-free. If \( w[i_1..i_2] \) and \( w[i_1..i_3] \) are privileged words with \( i_3 > i_2 \), then
\[
\frac{|w[i_1..i_3]|}{|w[i_1..i_2]|} \geq 1 + \frac{1}{k-1}.
\]
Proof. By Lemma 5, the word \( w[i_1..i_3] \) is \( (i_3 - i_2) \)-periodic; the rest of the proof is completely analogous to that of Lemma 3. □

Now, using this lemma, we analogously to Theorem 1 prove the following

**Theorem 7** Let \( k \) be a positive integer and \( w = w_1w_2 \ldots \in A^\mathbb{N} \). If \( w \) is \( k \)-power free, then for each positive integer \( P \) there exist a prefix \( u \) of \( w \) with \( |w|_{\text{priv}} > P \).

Instead of privileged words, we could use words of any other type for which a statement analogous to Lemmas 3 and 6 would hold. However, the proof of the next more general statement uses substantially the properties of palindromes and not any other family of words.

### 4 The case of the \((k, l)\)-condition

Recall that a fractional power \( w^{p/q} \) of a word \( w \) whose length \( |w| \) is divisible by \( q \) is defined as the word \( w^{[p/q]}w' \), where \( w' \) is the prefix of \( w \) of length \( \{p/q\}|w| \). To state the next, more general case for which we can prove the unboundedness of the palindromic length, let us fix some integer \( k > 0 \) and define a \( k \)-run in a word \( w \) as follows: a \( k \)-run is an occurrence \( w[i..j] \) such that the word \( w[i..j] \) is a \( k' \)-power for some (possibly fractional) \( k' \geq k \), but neither \( w[i-1..j] \) nor \( w[i..j+1] \) are \( k'' \)-powers for any \( k'' \geq k \).

Several problems on the maximal number and the sum of exponents of runs in a finite word have been studied, e. g., in [2, 3].

**Example 1** The word \( v = 1(100)^5101(001)^711 \) has two 5-runs, namely, \( v[2..18] = (100)^{17/3} \) and \( v[18..40] = (010)^{23/3} \). They are also 2-runs, 3-runs and 4-runs; the latter is also a 6-run and a 7-run. There are no 8-runs in \( v \).

Note that \( k \)-runs are defined as occurrences of words, or, in fact, as pairs of positions corresponding to their beginnings and ends. So, we can say that a \( k \)-run \( w[i..j] \) covers a position \( x \) of the word \( w \) if \( i + 1 \leq x \leq j - 1 \). Clearly, a position can be covered by an arbitrary number of \( k \)-runs, and even by an infinite number of them.

**Example 2** The third letter in the word \( v = 0001001001010100101001001 \) is covered by three 3-runs: \( v[1..3] = 0^2 \), \( v[2..11] = (001)^{10/3} \) and \( v[3..26] = (01001001)^3 \).

The position 1 in the infinite word defined as the limit of the sequence \( \{s_i\}_{i=1}^\infty \), where \( s_1 = 0001 \), \( s_{i+1} = s_i^2 \), is covered by an infinite number of 3-runs.

Let us denote the number of \( k \)-runs covering position \( n \) in a word \( w \) by \( r_{w,k}(n) \) or simply by \( r_k(n) \) if \( w \) is fixed in advance. The maximal value of \( r_k(n) \) for \( i \leq n \leq j \) is denoted by \( r_k[i..j] \).

We say that an infinite word \( w \) satisfies the \((k, l)\)-condition for some \( k \geq 2 \) and \( l \geq 0 \) if it is not ultimately periodic and \( r_{w,k}(n) \leq l \) for all \( n \), that is, if each position \( n \) in \( w \) is covered by at most \( l \) many \( k \)-runs.

**Example 3** The Sierpinski word \( w_s = 0101110101^8010111010127 \ldots \), defined as the fixed point starting with 0 of the morphism \( \varphi : 0 \mapsto 010, 1 \mapsto 111 \), satisfies the \((3, 1)\)-condition. Indeed, the only primitive factor \( u \) whose powers at least 3 occur in \( w_s \) is 1, and thus there is at most one 3-run covering each position in it.
Remark 1 We have not managed to find a proof of this statement in the literature, but it seems very believable that for any morphic word \( w \) there exists some \( k \) such that there exists only a finite number of primitive words whose powers greater than \( k \) occur in \( w \). If it is true, it means almost immediately that all the morphic words satisfy a \((k, 1)\)-condition for some \( k \), and thus that all aperiodic morphic words have unbounded palindromic length of factors.

The following theorem is a generalization of Theorem 1 which corresponds to the particular case of \( l = 0 \). Note that it is stated for a factor of the word \( w \), not for its prefix.

Theorem 8 If an infinite word \( w \) satisfies the \((k, l)\)-condition for some \( k \geq 2 \) and \( l \geq 0 \), then for each given \( P > 0 \) it contains a factor \( u \) with \(|u|_{\text{pal}} > P \).

The remaining part of the section is devoted to the proof of this theorem. The scheme of the proof is the following. In the first part of the proof we are going to introduce a new measure of words, so that the ratio of measures of two palindromes starting from a point is at least \( 1 + \frac{C}{k} \) for some constant \( C \) (Lemma 19). In the second part of the proof we choose a factor of big enough measure and deduce that the factorizations of prefixes of this factor into \( P \) cannot cover all the prefixes. Hence we derive the existence of a factor with palindromic length greater than \( P \).

First of all, note that if there exist arbitrarily long parts \( w[i..j] \) of \( w \) with \( r_k[i..j] = 0 \), then we can proceed as in the proof of Theorem 1 and find a prefix of palindromic length greater than \( P \) in any factor \( w[i..i+N] \) of \( w \) such that \( r_k[i..i+N] = 0 \) and \( (2 + \log_{k/(k−1)} N)^P < N \). So, in the main case of the theorem the length of factors of \( w \) not intersecting with any \( k \)-runs is bounded, and in particular \( w \) contains an infinite number of \( k \)-runs. So, from now on we assume that \( w \) satisfies this condition.

Let us say that a \( k \)-run \( w[i..j] \) is an upper \( k \)-run in \( w \) if it is not covered by another \( k \)-run, that is, if there is no \( k \)-run \( w[i'..j'] \) not equal to \( w[i..j] \) such that \( i' < i < j < j' \). For each position \( n \) in \( w \), we define by \( m_k(n) = m(n) \) the number of upper \( k \)-runs of the form \( w[n..i] \) or \( w[i..n] \).

Example 4 Consider the word \( v = 11(1000)^30 \). In it, \( v[1..3] = 111, v[3..14] = (1000)^3 \) and \( v[12..15] = 0000 \) are upper 3-runs, whereas the 3-runs \( v[4..6] = 000 \) and \( v[8..10] = 000 \) are not upper since they are covered by \( v[3..14] = (1000)^3 \). Also, we have \( m(3) = 2, m(1) = m(12) = m(14) = m(15) = 1 \) and \( m(n) = 0 \) for any other \( n \); here \( m(n) \) is exactly the number of occurrences of the position \( n \) in the notation of the upper 3-runs, which are \( v[1..3], v[3..14] \) and \( v[12..15] \).

Lemma 9 For each \( n \) we have \( 0 \leq m(n) \leq 2 \).

Proof. At each position \( n \) of \( w \) there is at most one upper \( k \)-run beginning in position \( n \) and at most one upper \( k \)-run ending in position \( n \), so \( 0 \leq m(n) \leq 2 \).

Now let us define the measure \( m[i..j] \) of an occurrence \( w[i..j] \) as the sum

\[
m[i..j] = \sum_{n=i}^{j} m(n).
\]

Clearly, it is indeed a measure, that is, the function \( m[i..j] \) is non-negative, equal to 0 for the empty word \( w[i..i-1] \) for any \( i \), and the measure of a disjoint union is the sum of measures, which means in particular that
Lemma 10  For all $i_1 \leq i_2 < i_3$ we have
\[ m[i_1..i_3] = m[i_1..i_2] + m[i_2 + 1..i_3]. \]
\[ \square \]

Note also that the function $r_k[i..j]$ is defined as the maximum of $r_k(n)$ for $n \in \{i, \ldots, j\}$, and is uniformly bounded by $l$ due to the $(k, l)$-condition, whereas $m[i..j]$ is defined as the sum of $m(n)$ and is not uniformly bounded since otherwise $w$ would contain a finite number of $k$-runs. Recall that we assume that the length of factors of $w$ not intersecting with any $k$-runs is uniformly bounded, since otherwise we simply apply the proof of Theorem \[1\]. This gives us

Lemma 11  There exists a unique $l'$, $1 \leq l' \leq l$, such that

- there exists some $M > 0$ such that $m[i..j] \geq M$ implies $r_k[i..j] \geq l'$;
- for all $L$ there exist $i, j$ such that $m[i..j] \geq L$ and $r_k[i..j] \leq l'$.
\[ \square \]

In the remaining part of the proof we shall always consider (occurrences of) factors of $w$ with $r_k[i..j] \leq l'$: due to the lemma above, their measure can be arbitrarily large. Due to the same lemma, each part of such a word whose measure is at least $M$ must contain a position covered by exactly $l'$ of $k$-runs.

Let us say that a $k$-run $w[j_1..j_2]$ is an internal run within an occurrence $w[p_1..p_2]$ if it intersects it but does not cover positions $p_1$ or $p_2$, that is, if $p_1 < j_1 < j_2 < p_2$. Similarly, a $k$-run $w[j_1..j_2]$ is called a left $k$-run in a word $w[p_1..p_2]$ if it covers the position $p_1$ but not $p_2$, that is, $j_1 \leq p_1 \leq j_2 < p_2$; symmetrically, it is a right $k$-run if it covers the position $p_2$ but not $p_1$, that is, $p_1 < j_1 \leq p_2 \leq j_2$. At last, it is a covering $k$-run if it covers both ending positions, that is, if $j_1 \leq p_1 < p_2 \leq j_2$.

Lemma 12  Each $k$-run intersecting with an occurrence $w[p_1..p_2]$ is either internal, or left, or right, or covering.

Proof. The four cases are determined by two facts: if the symbols $w[p_1$ and $w[p_2$ are parts of the $k$-run.
\[ \square \]

Lemma 13  If $w[p_1..p_2] = w[q_1..q_2]$ and $w[p_1 + i..p_2 - j]$ for some $i, j > 0$ is an internal $k$-run for $w[p_1..p_2]$, then $w[q_1 + i..q_2 - j]$ is an internal $k$-run in $w[q_1..q_2]$. However, the sets of left, right and covering runs depend on an occurrence of a word, and thus can be completely different for $w[p_1..p_2]$ and for $w[q_1..q_2]$. Moreover, if $w[p_1 + i..p_2 - j]$ is an upper $k$-run, it does not imply that $w[q_1 + i..q_2 - j]$ is an upper $k$-run, and vice versa.

Proof. If $w[p_1..p_2] = w[q_1..q_2] = u = u_1 \cdots u_n$, where $n = p_2 - p_1 + 1 = q_2 - q_1 + 1$, then $w[p_1 + i..p_2 - j] = u_{i+1} \cdots u_{n-j} = v$. By the maximality in the definition of a $k$-run, we see that the symbols $u_i$ and $u_{n-j+1}$ break the periodicity of $v$, so the $k$-run always starts at the symbol number $i+1$ of $u$ and ends at its symbol number $n-j+1$.

To give an example for the second part of the statement, consider the word
\[ aba.bb.aba.a^{k-2}.aba.bb.(aba)^k cu', \]
where the infinite word $w'$ is on the alphabet $\{b, c\}$. We see that in the first occurrence of $aba$ in it, there are no left, right or covering $k$-runs; in the second one, there is a right $k$-run $a^k$, which is also a left run for the third occurrence of $aba$; and the fourth occurrence of $aba$ is a prefix of a $k$-run $(aba)^k$ covering it.

6
At last, one occurrence of a word can be an upper internal $k$-run whereas another occurrence is not an upper one. As an example, consider the word

$$(ba^k b)^k bb ba^k bcw' ,$$

where $w'$ does not contain the symbol $a$. We see that in the first $k$ occurrences of $ba^k b$ the $k$-runs $a^k$ are covered by the $k$-run $(ba^k b)^k b$, and in the last one, the $k$-run $a^k$ is an upper one.  

To state the next lemma, symmetric to the first part of the previous one, we denote by $\tilde{v}$ the mirror image $v_n v_{n-1} \ldots v_1$ of a word $v = v_1 \ldots v_n$. In particular, a palindrome is exactly a word $v$ such that $v = \tilde{v}$.

**Lemma 14** If $w[p_1..p_2] = v$ and $w[q_1..q_2] = \tilde{v}$, and if $w[p_1 + i..p_2 - j]$ for some $i, j > 0$ is an internal $k$-run within $w[p_1..p_2]$, then $w[q_1 + j..q_2 - i]$ is an internal $k$-run in $w[q_1..q_2]$.

**Proof.** It is sufficient to realize that if $v[i..j]$ is an internal $k$-run within $v = v_1 \ldots v_n$, then $\tilde{v}[n - j + 1..n - i + 1]$ is an internal $k$-run withing $\tilde{v} = v_1 \ldots \tilde{v}_n = v_n \ldots v_1$.

**Lemma 15** The number of left (resp., right) $k$-runs for $w[p_1..p_2]$ is bounded by $r(p_1)$ (resp., $r_k(p_2)$) and thus by $r_k[p_1..p_2]$.

**Proof.** The $k$-runs covering the position $p_1$ are left or covering runs for $w[p_1..p_2]$, and their total number is $r_k(p_1)$. Symmetrically, the $k$-runs covering the position $p_2$ are right or covering runs for $w[p_1..p_2]$, and their total number is $r_k(p_2)$.

**Lemma 16** The set of covering runs for $w[p_1..p_2]$ can be non-empty only if $m[p_1..p_2] \leq 2r_k[p_1..p_2]$.

**Proof.** Suppose that there is a $k$-run covering $w[p_1..p_2]$. Then every $k$-run $w[q_1..q_2]$ contributing to the measure of $w[p_1..p_2]$ satisfy the following condition: one of the values $q_1, q_2$ lies inside the interval $[p_1..p_2]$, the other one outside. In other words, either $p_1 < q_1$, $p_1 \leq q_2 < p_2$, or $p_1 \leq q_1 \leq p_2, p_2 < q_2$. The number of $k$-runs satisfying the first condition is at most $r_k(p_1)$, the number of $k$-runs satisfying the second condition is at most $r_k(p_2)$, and each of them contributes at most 1 to the measure. Therefore, $m[p_1..p_2] \leq r_k(p_1) + r_k(p_2) \leq 2r_k[p_1..p_2]$.

The following two “lemmas of inviolable parts” are crucial for the proof. The first one is stated for an occurrence of $\tilde{v}$ and the second one for an occurrence of $v$, since it is what we need further in the proof, but in fact both of them can be stated both for $v$ and for $\tilde{v}$.

**Lemma 17** If $w[i_1..i_2] = v$, $r_k[i_1..i_2] = l'$, and $m[i_1..i_2] \geq M + 4l'$, where the parameters $l'$ and $M$ are defined in Lemma 11, then $m[j_1..j_2] \geq 2$ for all $j_1, j_2$ such that $w[j_1..j_2] = \tilde{v}$ and $r_k[j_1..j_2] \leq l'$.

**Proof.** Due to Lemma 16 there are no $k$-runs covering $w[i_1..i_2]$. Consider the maximal $q_1 \in \{i_1, \ldots, i_2 - 1\}$ such that $w[x..q_1]$ is a left $k$-run for $w[i_1..i_2]$; this $k$-run is a covering one for $w[i_1..q_1]$, and thus due to Lemma 16 $m[i_1..q_1] \leq 2r_k[i_1..q_1] \leq 2r_k[i_1..i_2] = 2l'$. If there are no left $k$-runs in $w[i_1..i_2]$, we put $q_1 = i_1 - 1$, and thus $m[i_1..q_1] = 0$ since it is an empty word. So, due to Lemma 10 we have $m[q_1 + 1..i_2] = m[i_1..i_2] - m[i_1..q_1] \geq M + 2l'$.

Now symmetrically, due to Lemma 16 there are no $k$-runs covering $w[q_1 + 1..i_2]$. Consider the minimal $q_2 \in \{i_1 + 1, \ldots, i_2\}$ such that $w[q_2..y]$ is a right $k$-run for $w[i_1..i_2]$. In fact we have $q_2 \geq q_1 + 2$ since otherwise $w[q_2..y]$ is a covering $k$-run for $w[q_1 + 1..i_2]$, a contradiction. So, the $k$-run $w[q_2..y]$ is a right $k$-run for $w[q_1 + 1..i_2]$ and a covering one for $w[q_2..i_2]$, and thus due to Lemma 16 $m[q_2..i_2] \leq 2r_k[q_2..i_2] \leq 2r_k[i_1..i_2] = 2l'$. If there are no right $k$-runs in $w[i_1..i_2]$, we
Lemma 18 If \( w[i_1..i_2] = v \), \( r_k[i_1..i_2] = \ell' \), and \( m[i_1..i_2] = 2M + 4\ell' + 2 + C \), where the parameters \( \ell' \) and \( M \) are defined in Lemma 14 and \( C \) is some positive constant, then \( m[j_1..j_2] \geq C \) for all \( j_1, j_2 \) such that \( w[j_1..j_2] = v \) and \( r_k[j_1..j_2] \leq \ell' \).

Proof. As in the previous lemma, there are no \( k \)-runs covering \( w[i_1..i_2] \); and after we cut from \( w[i_1..i_2] \) the longest prefix \( w[i_1..q_1] \) covered by some left \( k \)-run and the longest suffix \( w[q_2..i_2] \) covered by some right \( k \)-run, we get a factor \( w[q_1 + 1..q_2 - 1] \) of measure \( m[q_1 + 1..q_2 - 1] \geq 2M + 2 + C \) such that all \( k \)-runs intersecting with it are internal \( k \)-runs for \( w[i_1..i_2] \). We illustrate the proof of Lemma 18 by Fig. 4. The “inviolable part” shown there is the word \( w[i_1 + n_1..i_1 + n_2] \), whose measure \( m[i_1 + n_1..i_1 + n_2] \) does not depend on an occurrence of \( v \) to \( w \).

Consider the minimal prefix \( w[q_1 + 1..p_1] \) and the minimal suffix \( w[p_2..q_2 - 1] \) of \( w[q_1 + 1..q_2 - 1] \) such that \( m[q_1 + 1..p_1] \geq M \) and \( m[p_2..q_2 - 1] \geq M \). Due to Lemma 3, we have \( m[q_1 + 1..p_1] \leq M + 1 \) and \( m[p_2..q_2 - 1] \leq M + 1 \), and thus due to Lemma 10, \( m[p_1 + 1..p_2 - 1] \geq C \). At the same time, due to the definition of \( M \), there are positions \( i_1 + n_1 \) in \( w[q_1 + 1..p_1] \) and \( i_1 + n_2 \) in \( w[p_2..q_2 - 1] \) such that \( r_k(i_1 + n_1) = r_k(i_1 + n_2) = \ell' \). All the \( \ell' \)-runs contributing to \( r_k(i_1 + n_1) \) (resp., \( r_k(i_1 + n_2) \)) are internal \( k \)-runs for \( w[i_1..i_2] \) and thus do not depend on the occurrence of \( v = w[i_1..i_2] \). So, in another occurrence \( v = w[j_1..j_2] \) of \( v \) we have \( r_k(j_1 + n_1) = r_k(j_1 + n_2) = \ell' \), and all the \( k \)-runs contributing to \( r_k(j_1 + n_1) \) (resp., \( r_k(j_1 + n_2) \)) are internal \( k \)-runs for \( w[j_1..j_2] \).

In Fig. 4 the “inviolable part” shown there is the word \( w[i_1 + n_1..i_1 + n_2] \), whose measure \( m[i_1 + n_1..i_1 + n_2] \) does not depend on an occurrence of \( v \) in \( w \).

The following fact is analogous to Lemma 3.

Lemma 19 Suppose that an infinite word \( w \) satisfies the \((k, l)\)-condition, and the constants \( \ell' \) and \( M \) are defined by Lemma 14. If \( w[i_1..i_2] \) and \( w[i_1..i_3] \) are palindromes, where \( i_3 > i_2 \),
Consider the prefix $C$ of this definition, we have a position giving the measure obtained from the word $w[i_1..i_3]$ of big enough measure (the required measure depends on $P$ and several parameters of the word), we obtain that the number of possible codes of factorizations of prefixes of $w[i..j]$ into at most $P$ palindromes is less than the length of the code $C[i..j]$. We deduce from that the existence of a prefix of $w[i..j]$ not decomposable to $P$ palindromes.

Consider a factor $w[i..j]$ with $r_k[i..j] \leq l'$ of big enough measure (“long” factor). The required measure $N$ is determined below by \[2\]. Define the code $C[i..j]$ as a word on the alphabet $\{1,2\}$ obtained from the word $m(i)m(i+1)\cdots m(j)$ by erasing the symbols equal to 0. The length of the code $C[i..j]$ is denoted by $c[i..j]$; clearly,

$$m[i..j]/2 \leq c[i..j] \leq m[i..j],$$

(1)

since in fact $m[i..j]$ is the sum of the symbols of $C[i..j]$, and each of them is equal to 1 or 2.

If $i$ and $j$ are fixed, consider the word $m(i)m(i+1)\cdots m(j) \in \{0,1,2\}^*$ and denote by $n_h$ the position giving the $h$th non-zero symbol in it, so that $m(n_h) \in \{1,2\}$ for all $h = 1, \ldots, c$ and $m(n) = 0$ for all other $n \in \{i,i+1,\ldots,j\}\setminus\{n_1, n_2, \ldots, n_c\}$. We also define $n_0 = i - 1$. Due to this definition, we have $C[i..j] = a_1\cdots a_c$ with $a_h \in \{1,2\}$ and $m(n_h) = a_h$ for all $h = 1, \ldots, c$.

**Example 5** Consider the prefix $w[1..25] = 01011101011111110101110$ of the Sierpinski word $w$, considered as a word satisfying the $(3,1)$-condition. Its code is $C[1..25] = 111111$, and the positions $n_1, \ldots, n_6$ are equal to $4,6,10,18,22,24$: these are exactly first and last positions of 3-runs in $w$, that is, of “long” powers of 1. We also fix $n_0 = 0$. 

$$r_k[i_1..i_3] \leq l' \text{ and } m[i_1..i_2] \geq (k-1)(4l' + 2M + 3), \text{ then}$$

$$m[i_1..i_3] = m[i_1..i_2] \geq 1 + \frac{1}{(k-1)(4l' + 2M + 3)}.$$

**Proof.** By Lemma \[2\] the word $w[i_1..i_3]$ is $(i_3 - i_2)$-periodic. Denote its suffix $w[i_2 + 1..i_3]$ by $v$ and define $k'$ so that $w[i_1,i_2] = v^{(k'-2)}$ and thus $w[i_1..i_3] = v^{(k'-1)}$ for some suffix $v'$ of $v$ not equal to $v$ (here $v'$ can be empty) and for some $k' \geq 2$. Then $k' \leq k$ since otherwise $w[i_1..i_3]$ would have been covered by some $k$-run which is impossible due to Lemma \[16\].

Suppose that $m[i_1,i_2] = (k-1)(4l' + 2M + 2 + C)$ for some constant $C$. Here by the assertion we have $C \geq 1$; note that $C$ can be non-integer. Due to Lemma \[10\] the measure of $w[i_1..i_2]$ is the sum of measures of its prefix $v'$ and of $k' - 2$ occurrences of $v$. By the pigeon-hole principle, it means that some of these occurrences of $v$ (or of $v'$) have measure at least $4l' + 2M + 2 + [C]$. It means by Lemma \[18\] that the measure $m[i_2 + 1..i_3]$ of another occurrence $w[i_2 + 1..i_3]$ of $v$ is at least $C$. So, due to Lemma \[10\] again, we have

$$\frac{m[i_1..i_3]}{m[i_1..i_2]} = 1 + \frac{m[i_2 + 1..i_3]}{m[i_1..i_2]} \geq 1 + \frac{C}{(k-1)(4l' + 2M + 2 + C)}.$$

The right hand side of this inequality is a growing function of $C$ for $C \geq 1$, so the minimal value of $C = 1$ gives its minimum, and we have

$$\frac{m[i_1..i_3]}{m[i_1..i_2]} \geq 1 + \frac{1}{(k-1)(4l' + 2M + 3)}.$$

Now we proceed to the second part of the proof, where we are going to use Lemma \[19\] to prove that there should be a factor with palindromic length greater than $P$. The sketch of the remaining part of the proof is the following. We assign to each factor $w[i..j]$ its code $C[i..j]$, which is a word on a binary alphabet. We code each factorization $\mathbb{P}$ of a prefix of $w[i..j]$ into palindromes by a code $C^*(i..j, \mathbb{P})$, which is obtained from $C[i..j]$ by inserting symbols to positions between the palindromes. After that, taking a factor $w[i..j]$ of big enough measure (the required measure depends on $P$ and several parameters of the word), we obtain that the number of possible codes of factorizations of prefixes of $w[i..j]$ into at most $P$ palindromes is less than the length of the code $C[i..j]$. We deduce from that the existence of a prefix of $w[i..j]$ not decomposable to $P$ palindromes.
Consider a factorization into palindromes of a prefix $w[i..i']$ of $w[i..j]$: $w[i..i'] = w[i_0+1..i_1]w[i_1+1..i_2] \cdots w[i_{p-1}+1..i_p]$, where $i = i_0 + 1$, $i_p = i'$, and each word $w[i_d+1..i_{d+1}]$ is a palindrome. Define the partition to palindromes $P$ as the sequence $P = \{i_0, i_1, \ldots, i_p\}$, and the code of this partition in $w[i..j]$ as the word $C^*(i..j), i_1, \ldots, i_p = C^*(i..j), P$ on the alphabet $\{1, 2, \ast\}$ obtained from the code $C(i..j)$ by adding a star before the symbol $a_h$ for each $d$ such that $n_{h-1} \leq i_d < n_h$. Note that the number of stars in the code of a partition to $P$ palindromes is exactly $P + 1$.

**Example 6** Continuing the previous example, consider the following partition to palindromes of a prefix of length 22 of the Sierpinski word $w$, considered in its turn as a prefix of $w[1..25]$:

$$(010)(11)(10101111111101011)_{110}.$$ We see that $i_0 = 0$, $i_1 = 3$, $i_2 = 5$, $i_3 = 22$, $P = \{0, 3, 5, 22\}$, and thus the code of this partition is $C((1..25), 3, 5, 22) = C((1..25), P) = \ast \ast 1 \ast 1111 \ast 1$.

The stars correspond to the boundaries of palindromes, and the symbols 1 and 2 correspond to beginnings and ends of upper $k$-runs in $w[i..j]$. Note that the code of a partition of a prefix of $w[i..j]$ always begins with a star.

We are going to prove that if $c[i..j]$ is large enough, then there is a pair of consecutive symbols from $\{1, 2\}$ in $C[i..j]$ such that no partition $P$ of a prefix of $w[i..j]$ to at most $P$ palindromes has a star between them in $C^*(i..j), P$. In particular it means that there is a prefix of $w[i..j]$ with palindromic length greater than $P$, and thus we prove Theorem 8.

**Lemma 20** Suppose that for the word $w[i..j]$ considered above we have $c[i..j] = N$ and $i'$, $i \leq i' \leq j$ is a position such that $i' = n_h - 1$ for some $h$, $1 \leq h \leq N$. Then the number of values of $h'$ such that there exists $i''$ with $w[i'+1..i'']$ being a palindrome and $n_{h'-1} \leq i'' < n_{h'}$, is bounded by $H = D_1 + 1 + \log_{D_2}(2N/D_1)$, where $D_1 = (k-1)(4l'+2M+3)$ and $D_2 = 1 + \frac{1}{D_1}$.

**Proof.** The fact that $c[i..j] = N$ means in particular that $m[i..j] \leq 2N$ due to [1]. We shall estimate the number of possible values of $m[i'+1..i'']$ not exceeding $2N$, where $w[i'+1..i'']$ is a palindrome, and this will give an upper bound for the number of values of $h'$, since $n_h$ are the positions where the measure changes.

First of all, $m[i'+1..i'']$ can take at most $(k-1)(4l'+2M+3) + 1 = D_1 + 1$ values of $h'$ from 0 to $(k-1)(4l'+2M+3)$. Due to Lemma 19 the value of $h'$ numbered $D_2$ must be equal at least to $D_1D_2$, where $D_2 = 1 + \frac{(k-1)(4l'+2M+3)}{D_1} = 1 + \frac{1}{D_1}$, and the value of $h'$ number $D_1 + n + 1$ is equal at least to $D_1D_2^2$. Even for the maximal $n$ we should have $D_1D_2^2 \leq 2N$, so that $n \leq \log_{D_2}(2N/D_1)$, and the total possible number of measures of palindromes is bounded by $D_1 + 1 + \log_{D_2}(2N/D_1)$.

**Lemma 21** Suppose that for the word $w[i..j]$ considered above we have $c[i..j] = N$ and $i'$, $i \leq i' \leq j$ is a position such that $n_{h-1} \leq i' < n_h$ for some $h$, $1 \leq h \leq N$. Then the number of values of $h'$, such that there exists $i''$ with $w[i'+1..i'']$ being a palindrome and $n_{h'-1} \leq i'' < n_{h'}$, is bounded by $(M + 4l')\log_{D_2}(2N/D_1) + D_3$, where, as above, $D_1 = (k-1)(4l'+2M+3)$, $D_2 = 1 + \frac{1}{D_1}$, and $D_3 = (M + 4l')^2 + M + 4l' + D_1 + 1$.

**Proof.** As in the previous lemma, we shall estimate the number of possible values of $m[i'+1..i'']$ not exceeding $2N$, where $w[i'+1..i'']$ is a palindrome. As above, $m[i'+1..i'']$ can take at most $(k-1)(4l'+2M+3) + 1 = D_1 + 1$ values from 0 to $(k-1)(4l'+2M+3) = D_1$.  

10
Suppose now that \(m[i'+1..i''] > D_1\), and consider the prefix \(w[i'+1..n_h-1]\) of \(w[i'+1..i'']\); note that by the definition of the sequence \(\{n_h\}\), its measure \(m[i'+1..n_h-1] = 0\), and the measure of \(w[n_h..i'']\) is equal to that of \(w[i'+1..i'']\).

Suppose first that \(n_h - i' - 2 \geq i'' - n_h\), that is, \(w[i'+1..n_h-1] = t\) contains the center of the palindrome \(w[i'+1..i''] = u\). It means that \(u = tv = \bar{v}t'v\) and \(t = \bar{v}t'\) for some words \(v\) and \(t'\). We see that the measure of the occurrence of \(\bar{v}\) starting from \(i' + 1\) is equal to 0, and thus, due to Lemma [17] we have \(m[i'+1..i''] = m[n_h..i''] < M + 4l'\), a contradiction to the fact that \(m[i'+1..i''] > D_1\).

Now suppose that \(n_h - i' - 2 < i'' - n_h\), that is, \(w[i'+1..n_h-1] = t\) is shorter than a half of \(w[i'+1..i''] = u\). It means that \(u = tvt\) for some palindromes \(v\) starting from the position \(n_h\). Let us denote the measure of \(v\) by \(m\). The measure of the prefix occurrence of \(t\) is here equal to 0; so, due to Lemma [17] the measure of the suffix occurrence of \(\bar{v}\) is at most \(M + 4l' - 1\). So, we have \(m \leq m[i'+1..i''] \leq m + M + 4l' - 1\), so, for each possible value of \(m \geq D_1 - (M + 4l')\), the measure \(m[i'+1..i'']\) takes at most \(M + 4l'\) different values. Adding possible values from 0 to \(D_1\), we see that the total number of values is bounded by \(D_1 + 1 + (M + 4l')(H - D_1 + M + 4l')\), where \(H\) is the bound for the number of measures of palindromes starting from \(n_h\) obtained in Lemma [20], so that \(H = D_1 + 1 + \log_{D_3}(2N/D_1)\). Simplifying the expression, we obtain that \(D_1 + 1 + (M + 4l')(H - D_1 + M + 4l') = (M + 4l')\log_{D_2}(2N/D_1) + (M + 4l')(M + 4l' + 1) + D_1 + 1 = (M + 4l')\log_{D_2}(2N/D_1) + D_3\).

**Proof of Theorem 8.** Fix a positive integer \(P\) and let \(N\) be a positive integer satisfying

\[
(M + 4l')\log_{D_2}(2N/D_1) + D_3 < N,
\]

where the constants \(D_1\)–\(D_3\) are defined in Lemma [21]. Consider a factor \(w[i..j]\) of \(w\) with \(r_k[i..j] \leq l'\) and \(c[i..j] = N\); such a factor \(w[i..j]\) always exists by the definitions of \(l'\) and of \(c[i..j]\). By the previous lemma, the number of possible codes of decompositions of prefixes of \(w[i..j]\) to \(P\) palindromes \(w[i_d+1..i_{d+1}]\), \(d = 0, \ldots, P-1\), is at most \([(M + 4l')\log_{D_2}(2N/D_1) + D_3]^P\), and hence less than \(N\). In particular it means that the position of the last star in the code can take less than \(N\) different values; but the length \(c[i..j]\) of the code of \(w[i..j]\) is \(N\). So, there are two consecutive symbols in \(c[i..j]\), corresponding to the positions \(n_h\) and \(n_{h+1}\), such that the last star in the code of the decomposition to \(P\) palindromes can never appear between them, that is, that no word \(w[i..q]\), where \(n_h \leq q < n_{h+1}\), can ever be decomposed into \(P\) palindromes.

\section{Discussion}

Even if we prove that the palindromic length of factors of any aperiodic word is unbounded, some ultimately periodic words, for example, \(w = (110100)^\omega\), contain factors having arbitrarily large palindromic lengths. So, unlike for example the result by Mignosi, Restivo and Salemi on repetitions and periodicity [7], the conjectured property will not give a characterization of aperiodic words.

We prove the following property of ultimately periodic words with a uniform bound on the palindromic length of its factors:

**Proposition 22** Let \(P\) be an integer, \(w\) an ultimately periodic word such that \(|u|_{\text{pal}} \leq P\) for each factor \(u\) of \(w\). Then \(w\) has a tail \(w'\) of the form \(w' = v(p_1p_2)^\omega\), where \(p_1\) and \(p_2\) are palindromes.

**Proof.** Let \(w'\) be a tail of \(w\) having period \(t\). Consider a factor \(u\) of \(w'\) with \(|u| > tP\). Then \(u\) can be factored as \(u = v_1v_2\ldots v_m\) with \(m \leq P\) and each \(v_i\) a non-empty palindrome. At least
one of the palindromes $v_i$ in this factorization has length greater than $t$. So, $t$ is a period of this long palindrome. Now the proposition follows from the well-known fact that a period of a palindrome has the form $p_1p_2$, where $p_1$ and $p_2$ are palindromes.

Proposition 22 implies that if the answer to Question 1 is “no”, then an infinite word $w$ having a uniform bound on the palindromic length of its factors is ultimately periodic, and moreover its period has the form $p_1p_2$, where $p_1$ and $p_2$ are palindromes.

As we have mentioned above in Remark 1 the $(k,l)$-conditions for some $k$ and $l$ seems to be fulfilled in particular for all morphic words, so, it is hardly probable that an example of an aperiodic word with bounded palindromic length of factors will be a morphic word. At the same time, there exist Sturmian words which do not satisfy any $(k,l)$-condition: these are exactly Sturmian words whose elements of the directive sequence are unbounded (see Chapter 2 of [6] for the definitions). So, this paper does not contain a proof of unbounded palindromic length of factors which would be valid for all Sturmian words.

It is also clear that

**Lemma 23** If there exists an aperiodic word with bounded palindromic length of factors, then there exists a binary one.

**Proof.** Consider an aperiodic word $w$ on an alphabet $A = \{a_1, \ldots, a_q\}$ and for each $i \in 1, \ldots, q$ define a coding $c_i$ by $c_i(a_i) = 0$, $c_i(b) = 1$ for all other symbols $b \in A$. Consider the infinite words $c_1(w), \ldots, c_q(w)$. At least one of them, let us denote it by $c(w)$, is aperiodic (since otherwise $w$ would be periodic with the period equal to the least common multiple of periods of $c_1(w), \ldots, c_q(w)$). At the same time, for each factor $u$ of $w$ we have $|u|_{\text{pal}} \geq |c(u)|_{\text{pal}}$. So, if $|u|_{\text{pal}} \leq P$ for all factors $u$ of $w$ and for some $P$, then the same is true for all factors $c(u)$ of the binary aperiodic infinite word $c(w)$: $|c(u)|_{\text{pal}} \leq P$. □

**Remark 2** The proof of Lemma 23 above is valid only for the case of a finite alphabet $A$. Another proof, valid also for the infinite alphabet $\{0, 1, \ldots, n, \ldots\}$, was suggested by T. Hejda who uses the morphism $c$ defined by $c(i) = 10^i$. It is not difficult to prove that $|u|_{\text{pal}} \leq P$ for all factors $u$ of $w$, then $|v|_{\text{pal}} \leq P + 4$ for all factors $v$ of $c(w)$.

At last, we recall again that for the case of $k$-power-free words, our proof can be extended in particular to privileged words instead of palindromes (see Section 3). However, Theorem 8 cannot be directly extended to privileged words since in Lemma 21 we used the properties specific for palindromes which allowed to apply Lemma 17.
