Spectral stability of the critical front in the extended Fisher-KPP equation

Montie Avery and Louis Garénaux

Abstract. We revisit the existence and stability of the critical front in the extended Fisher-KPP equation, refining earlier results of Rottschäfer and Wayne (J Differ Equ 176(2):532–560, 2001) which establish stability of fronts without identifying a precise decay rate. Our main result states that the critical front is marginally spectrally stable, with essential spectrum touching the imaginary axis but with no unstable point spectrum. Together with the recent work of Avery and Scheel (SIAM J Math Anal 53(2):2206–2242, 2021; Commun Am Math Soc, 2:172–231, 2022), this establishes both sharp stability criteria for localized perturbations to the critical front, as well as propagation at the linear spreading speed from steep initial data, thereby extending front selection results beyond systems with a comparison principle. Our proofs are based on far-field/core decompositions which have broader use in establishing robustness properties and bifurcations of invasion fronts.

Keywords. Traveling waves, Pulled fronts, Spectral stability, Singular perturbations, Embedded eigenvalues.

1. Introduction

1.1. Background and main results

The extended Fisher-KPP equation

\[ u_t = -\delta^2 u_{xxxx} + u_{xx} + f(u), \quad f(0) = f(1) = 0, \quad \delta \in \mathbb{R} \quad (1.1) \]

is a fundamental model for understanding the dynamics of invasion fronts in systems without comparison principles [12] and may further be derived as an amplitude equation near certain co-dimension 2 bifurcations in reaction–diffusion systems [33]. Indeed, while rigorous results on front propagation from steep initial data are typically limited to equations with comparison principles, the marginal stability conjecture predicts that invasion speeds in spatially extended systems are universally predicted by marginal spectral stability of an associated invasion front [37]. In the current setting, such invasion fronts solve the traveling wave equation

\[ 0 = -\delta^2 q^{"'} + q'' + cq' + f(q), \quad q(-\infty) = 1, \quad q(\infty) = 0. \quad (1.2) \]

The review paper [37] presents many examples in which this conjectured behavior is observed in systems without comparison principles through numerical simulations, physical experiments, and formal asymptotic analysis. The lack of a comparison principle is essential to much of the interesting dynamics explored in [37], in which invasion fronts select features of periodic patterns generated in their wake. Concurrent to the present work, the first author and Scheel gave a rigorous proof of the marginal stability conjecture for unpatterned invasion in higher order parabolic systems, identifying precise spectral criteria which lead to selection of critical pulled fronts [5]. The present work establishes that these spectral assumptions hold for (1.1) for \( \delta \) sufficiently small, thereby establishing front selection in the absence of comparison...
principles and making progress toward understanding the dynamics of pattern-forming fronts explored in [37].

Here, we assume $f$ is of Fisher-KPP type: $f(0) = f(1) = 0$, $f'(0) > 0$, $f'(1) < 0$, and for instance $f''(u) < 0$ for all $u \in (0, 1)$; see Sect. 1.2 for comments on this last assumption. In this case, the marginal stability conjecture predicts that strongly localized initial data in (1.1) propagate with the linear spreading speed $c_*(\delta)$, a distinguished speed for which solutions to the linearization

$$u_t = -\delta^2 u_{xxxx} + u_{xx} + cu_x + f'(0)u$$

generically grow exponentially pointwise for $c < c_*(\delta)$ but decay for $c > c_*(\delta)$. The linear spreading speed may be more precisely characterized by the location of simple pinched double roots of the associated dispersion relation; see below for details. Our first result establishes the existence of a critical front traveling with the linear spreading speed, which was previously proved by Rottschäfer and Wayne using geometric singular perturbation theory [34].

**Theorem 1.** (Existence of the critical front) There exists $\delta_0 > 0$ such that for all $\delta \in (-\delta_0, \delta_0)$, there exists $c = c_*(\delta)$ and a smooth traveling front $q_*$ solving (1.2), such that

$$q_*(x; \delta) = (\mu(\delta) + x)e^{-\eta_*\delta x} + O(e^{-\eta_*\delta x + \eta x}), \quad \text{as } x \to \infty$$

for some $\eta > 0$, where $\delta \mapsto \eta_* \in C^1(-\delta_0, \delta_0)$, with $\eta_* = \sqrt{f''(0)} + O(\delta^2)$ when $\delta \to 0$, and $\delta \mapsto \mu(\delta)$ is continuous, with $\mu(0) = 1$. Moreover, $q_*(\cdot; \delta)$ depends continuously on $\delta$, uniformly in space.

Our proof is based on a far-field/core decomposition, relying only on basic Fredholm properties of the linearization about the critical front for $\delta = 0$ together with explicit preconditioners which regularize the singular perturbation. We believe our methods have further utility in describing bifurcations from the singular perturbation. We mention that the existence of both invasion fronts and fronts connecting two stable states in fourth-order parabolic equations, including the extended Fisher-KPP equation with $\delta$ not necessarily small, was established in [8] using topological arguments.

Perturbations $v(t, x - c_*(\delta)t) = u(t, x) + q_*(x - c_*(\delta)t; \delta)$ of the critical front in (1.1) solve

$$v_t = A(\delta)v + f(q_* + v) - f(q_*) - f'(q_*)v,$$

(1.3)

where $A(\delta) : H^4(\mathbb{R}) \subset L^2(\mathbb{R}) \to L^2(\mathbb{R})$ is the linearization about the critical front, defined through

$$A(\delta) := -\delta^2 \partial_x^4 + \partial_x^2 + c_\delta \partial_x + f'(q_*(x; \delta)).$$

(1.4)

The essential spectrum of the linearization $A(\delta)$ is unstable due to the instability of the background state $u \equiv 0$. Hence, to establish a stability result, one restricts to perturbations with prescribed exponential localization. The optimal exponential weight here matches the decay rate of the critical front; we therefore define

$$\omega_*(x; \delta) = \begin{cases} e^{\eta_*\delta x}, & x \geq 1, \\ 1, & x \leq -1, \end{cases}$$

(1.5)

so that the conjugate operator $L(\delta) = \omega_*(\cdot; \delta) A(\delta) \omega_*(\cdot; \delta)^{-1} : H^4(\mathbb{R}) \to L^2(\mathbb{R})$ describes the linearized dynamics of perturbations in this weighted space. The essential spectrum of $L(\delta)$ is marginally stable, touching the imaginary axis only at the origin; see Fig. 1 and Lemma 2.1 for details. Our main result establishes spectral stability for $L(\delta)$ as required by the marginal stability conjecture in light of [5].

**Theorem 2.** (Spectral stability) There exists a $\delta_0 > 0$ such that for all $\delta \in (-\delta_0, \delta_0)$ the operator $L(\delta)$ has no eigenvalues $\lambda$ with $\text{Re} \lambda \geq 0$, and there does not exist a bounded solution to $L(\delta)u = 0$.

Together with Lemmas 2.1 and 2.2 which control the essential spectrum, Theorem 2 says that the critical front is *marginally spectrally stable*, in the sense that
the essential spectrum of $\mathcal{L}(\delta)$ is contained entirely in the left half plane except for a single branch which touches the imaginary axis at the origin;

• the linearization $\mathcal{L}(\delta)$ has no unstable eigenvalues, or eigenvalues on the imaginary axis;

• there is no “embedded eigenvalue” (more precisely, no resonance pole of the Evans function) in the essential spectrum at $\lambda = 0$.

The results in [4] therefore imply nonlinear stability of the critical front against localized perturbations, with sharp decay rates and precise characterization of the leading order asymptotics. To state these, we first define for $r \in \mathbb{R}$ a smooth positive one-sided algebraic weight $\rho_r$ which satisfies

$$
\rho_r(x) = \begin{cases} 
1, & x \leq -1, \\
(1 + x^2)^{r/2}, & x \geq 1.
\end{cases}
$$

We then have the following nonlinear stability results.

**Corollary 1.1.** (Nonlinear stability) Let $r > \frac{3}{2}$ and $\delta_0 > 0$ as in Theorem 2. There exist constants $\varepsilon > 0$ and $C > 0$ such that if $\delta \in (-\delta_0, \delta_0)$ and $\|\omega_\ast(\cdot; \delta)\rho_r v_0\|_{H^1} < \varepsilon$, then

$$
\|\omega_\ast(\cdot; \delta)\rho_r v(t, \cdot)\|_{H^1} \leq \frac{C\varepsilon}{(1 + t)^{3/2}},
$$

where $v$ is the solution to (1.3) with initial data $v_0$. Furthermore if $r > \frac{5}{2}$, then there exists a real number $\alpha_\ast = \alpha_\ast(\omega_\ast(\cdot; \delta)\rho_r v_0)$, depending smoothly on $\omega_\ast(\cdot; \delta)\rho_r v_0$ in $H^1(\mathbb{R})$, such that for $t > 1$,

$$
\|\rho_r \omega_\ast(\cdot; \delta)(v(t, \cdot) - \alpha_\ast t^{-3/2} q_\ast(\cdot; \delta))\|_{H^1} \leq \frac{C\varepsilon}{(1 + t)^2}.
$$

Nonlinear stability of the critical front in the classical Fisher-KPP equation, $\delta = 0$, against localized perturbations was established by Kirchgässner [27] and later refined in [4,13,14,19]. The sharp $t^{-3/2}$ decay rate in this setting was first established in [19] and later reobtained in [4,14]. Crucial to this improved decay compared to the standard diffusive decay rate $t^{-1/2}$ is the lack of an embedded eigenvalue of the linearization at $\lambda = 0$, as captured here in Theorem 2, an observation made precise in [4]. Nonlinear stability of the critical front for $\delta \neq 0$ was obtained in [34] via weighted energy estimates, but without a precise characterization of the decay rate, while the $t^{-3/2}$ decay rate obtained here is sharp in light of the asymptotics given in Corollary 1.1.

**Remark 1.2.** The spectral stability obtained in Theorem 2, Lemma 2.1, and Lemma 2.2, together with the analysis in [5], confirms the marginal stability conjecture for (1.1), as stated in the upcoming Corollary 1.3. It confirms that open classes of steep initial data propagate with the linear spreading speed $c_\ast(\delta)$, up to a universal logarithmic delay, as predicted by the marginal stability conjecture [37]; see [5] for further details. In the classical Fisher-KPP equation, $\delta = 0$, analogous convergence results for non-negative steep data may be shown using comparison principles [1,22,28,29] or probabilistic methods [9,10]. We believe Corollary 1.3 represents an important step in extending results on front selection beyond equations with comparison principles and toward pattern-forming systems.

**Corollary 1.3.** (Front selection) Fix $r > 2$. For any $\varepsilon > 0$, there exists a class of initial data $\mathcal{U}_\varepsilon$, including some nontrivial data supported on a half-line, such that for any $u_0 \in \mathcal{U}_\varepsilon$, we have

$$
\sup_{x \in \mathbb{R}} |\rho_{-1}(x)\omega_\ast(x; \delta)[u(x + \sigma(t), t) - q_\ast(x; \delta)]| < \varepsilon,
$$

where $u$ is the solution to (1.1) with initial data $u_0$, and

$$
\sigma(t) = c_\ast(\delta)t - \frac{3}{2\eta_\ast(\delta)} \log t + x_\infty(u_0)
$$

for some $x_\infty(u_0) \in \mathbb{R}$. Moreover, $\mathcal{U}_\varepsilon$ is open in the topology induced by the norm $\|f\| = \|\rho_r \omega_\ast(\cdot; \delta)f\|_{L^\infty}$. 

Remark 1.4. While there are some limited results available on front propagation in some non-local equation without comparison principles (see e.g. [6,7]), these results rely on exploiting the specific structure of the equation to reduce the consideration to a scalar Fisher-KPP type equation to which comparison principle arguments may be applied. To the best of our knowledge, Corollary 1.3 is the first result establishing the marginal stability conjecture in which the comparison principle does not play any role in the nonlinear argument, and the first result for an equation higher than second order in space.

1.2. Remarks

Assumptions on \( f \). Since we prove our results by perturbing from the classical Fisher-KPP equation, our results hold for any smooth nonlinearity \( f \) which satisfies \( f(0) = f(1) = 0 \), \( f'(0) > 0 \), \( f'(1) < 0 \), and for which existence and spectral stability of the critical front hold for the classical Fisher-KPP equation with this reaction term. In particular, this is implied by the assumption \( f''(u) < 0 \) for \( u \in (0,1) \) [36, Theorem 5.5], which we state in the introduction. This can be weakened, for instance, to the assumption that \( 0 < f(u) \leq f'(0)u \) for \( u \in (0,1) \); see e.g. [1].

General approach – preconditioning. Our approach to regularizing the singular perturbation is based on preconditioning with an appropriately chosen operator. To illustrate the main idea, briefly consider the eigenvalue problem for the unweighted linearization, \((A(\delta) - \lambda)u = 0\). Applying \((1 - \delta^2 \partial_x^2)^{-1}\) to \(A(\delta) - \lambda\), we obtain

\[
(1 - \delta^2 \partial_x^2)^{-1}(A(\delta) - \lambda) = (1 - \delta^2 \partial_x^2)^{-1}[(1 - \delta^2 \partial_x^2)\partial_x^2 + c_*(\delta)\partial_x + f'(q_*) - \lambda]
\]

\[
= \partial_x^2 + (1 - \delta^2 \partial_x^2)^{-1}(c_*(\delta)\partial_x + f'(q_*) - \lambda)
\]

\[
= \partial_x^2 + c_*(\delta)\partial_x + f'(q_*(\cdot; \delta)) - \lambda + T(\delta)(c_*(\delta)\partial_x + f'(q_*(\cdot; \delta)) - \lambda),
\]

where \(T(\delta) = (1 - \delta^2 \partial_x^2)^{-1} - 1\). Once we prove that the terms involving \(T(\delta)\) are continuous in \(\delta\), the eigenvalue problem becomes essentially a regular perturbation of the classical Fisher-KPP linearization, at \(\delta = 0\). We prove the necessary estimates on the preconditioners using direct Fourier analysis in Sect. 2.3. This approach is inspired by that used to construct oblique stripe solutions in a quenched Swift-Hohenberg equation in [21].

Stability to less localized perturbations. We note that under the spectral stability conditions we prove here, in addition to Corollary 1.1, one also immediately obtains from the results of [4] stability under less localized perturbations, with a prescribed decay rate which is slower than \(t^{-3/2}\). See [4, Theorems 3 and 4] for details.

Geometric vs. functional analytic point of view. We remark here that one should also be able to prove the spectral stability results obtained here using geometric dynamical systems methods, in particular geometric singular perturbation theory in the sense of Fenichel [17] together with the gap lemma [20,26], which is used to extend the Evans function into the essential spectrum. An attractive feature of our approach here is that it is quite self contained, ultimately relying mostly on basic Fredholm theory and Fourier analysis. We also remark that in principle, the functional analytic methods could be adapted, together with the approach to linear stability through obtaining resolvent estimates via far-field/core decompositions in [4], to problems in stability of critical fronts in nonlocal equations, since these methods do not rely as heavily on the presence of an underlying phase space. Some of the relevant Fredholm theory for nonlocal operators has been developed in [15,16].

Bifurcations from pulled to pushed fronts. As explained in [5, Remark 1.2], weak exponential decay \(q(x) \sim (a + bx)e^{-\alpha x}, x \to \infty\) is an essential and generic feature of pulled fronts. Our far-field/core method for continuing pulled fronts, developed in the proof of Theorem 1, isolates this far-field term as the central contribution to the bifurcation argument, while the “core” piece is handled by appealing to general Fredholm properties. In general parameter dependent systems \(u_t = P(\partial_x)u + f(u; \delta)\), one can use
the methods of Theorem 1 to continue pulled fronts \( q(x; \delta) \), with far-field asymptotics,

\[
q(x; \delta) \sim (a(\delta) + b(\delta)x)e^{-\eta(\delta)x}, \quad x \to \infty.
\]  \hspace{1cm} (1.6)

From this perspective, one expects a bifurcation in the mode of front propagation to occur when \( b(\delta) \to 0 \) as \( \delta \to \delta_\ast \) for some \( \delta_\ast \), since at such a point the pulled front loses its characteristic weak exponential decay. This program has now been carried out in [3], adapting the methods developed here to give a generic description of the bifurcation from pulled to pushed front propagation, with associated numerical algorithms for continuing pushed and pulled fronts based on far-field/core decompositions.

**Natural range for \( \delta \).** In this paper, we have restricted to small \( \delta \). However, we believe that similar results should hold true for larger values of this parameter. While the existence of fronts is established in [8] for all speeds \( c > 0 \) and \( \delta \in \mathbb{R} \), we do not have access to explicit decay at \( +\infty \) for this fronts, which seems necessary to establish precise stability. Monotonicity of the front would imply such a precise decay by use of Ikehara’s theorem [11]. An important value is \( \delta = 1/\sqrt{12f'(0)} \), at which the dispersion relation admits a triple root, and the essential spectrum of the linearized operator becomes tangent to the imaginary axis. Stability at or above this value of \( \delta \) is therefore fundamentally outside the scope of [4].

**Supercritical and subcritical fronts.** If we consider a supercritical front, traveling with speed \( c > c_\ast(\delta) \) and constructed in [34], one can simplify the argument of Theorem 2 to prove that the linearization about such a front has no unstable point spectrum. For these fronts, one can use an exponential weight to push the essential spectrum entirely into the left half plane, and thereby with the analog of Theorem 2 obtain stability of supercritical fronts with an exponential decay rate using standard semigroup methods (see e.g. [23]). Subcritical fronts, with \( c < c_\ast(\delta) \), have unstable absolute spectrum, meaning in particular that the essential spectrum of the linearization about any of these fronts is unstable in any exponentially weighted space. A modified version of our proof of Theorem 1 should also give existence of these supercritical and subcritical fronts using functional analytic methods, although we do not give the details here.

**Additional notation** For \( r > 0 \), we let \( B(0, r) \) denote the ball of radius \( r \) centered at the origin in the complex plane. We will use the notation \( \langle u, v \rangle = \int \overline{u} \, \sigma \, dx \) to denote the standard inner product on \( L^2(\mathbb{R}, \mathbb{C}) \). We let \( \mathcal{B}(X, Y) \) denote the space of bounded linear operator between two Banach spaces \( X \) and \( Y \).

**Outline** The remainder of this paper is organized as follows: In Sect. 2, we compute some preliminary information needed for our analysis (the linear spreading speed in (1.2) and the cokernel of \( \mathcal{L}(0) \)) and prove some necessary estimates on our preconditioner. In Sect. 3, we use explicit preconditioners and a far-field/core decomposition to prove Theorem 1, establishing existence of the critical front. In Sect. 4, we define a functional analytic analog of the Evans function near \( \lambda = 0 \), and use it together with knowledge of the spectrum of \( \mathcal{L}(0) \) to prove that \( \mathcal{L}(\delta) \) has no resonance at the origin or unstable eigenvalues for \( \delta \) small. In Sect. 5, we complete the proof of Theorem 2 by showing that there are also no unstable eigenvalues away from the origin.

### 2. Preliminaries

#### 2.1. Exponential weights

In addition to the critical weight (1.5) which we use to shift the essential spectrum out of the right half plane, we will need further exponential weights to recover Fredholm properties of \( \mathcal{L}(\delta) \) and related operators for our far-field/core analysis. For \( \eta_\pm \in \mathbb{R} \), we define a smooth positive weight function \( \omega_{\eta_-, \eta_+} \) satisfying

\[
\omega_{\eta_-, \eta_+}(x) = \begin{cases} e^{\eta_- x}, & x \leq -1, \\ e^{\eta_+ x}, & x \geq 1. \end{cases}
\]
If \( \eta_- = 0 \) and \( \eta_+ = \eta \), then we write \( \omega_{\eta_-; \eta_+} = \omega_\eta \). If \( \eta_- = \eta_+ = \eta \), we choose \( \omega_{\eta, \eta}(x) = e^{\eta x} \).

Given an integer \( m \), we define the exponentially weighted Sobolev space \( H^m_{\eta_-; \eta_+}(\mathbb{R}) \) through the norm
\[
|f|_{H^m_{\eta_-; \eta_+}} = |\omega_{\eta_-; \eta_+} f|_{H^m}.
\]
We note that for \( \eta > 0 \) we have \( H^m_{0, \eta}(\mathbb{R}) = H^m(\mathbb{R}) \cap H^m_{\eta, \eta}(\mathbb{R}) \) as well as the following equivalence of norms
\[
|f|_{H^m_{\eta, \eta}} \sim |f|_{H^m} + |f|_{H^m_{\eta, \eta}}. \tag{2.1}
\]
This characterization of the one-sided weighted spaces is useful in obtaining estimates on operators defined by Fourier multipliers on these spaces, and we make use of this below in Sect. 2.3.

### 2.2. Linear spreading speed and essential spectrum

The linear spreading speed, marking the transition from pointwise growth to pointwise decay in the linearization about \( u \equiv 0 \), is characterized here by the location of simple pinched double roots of the dispersion relation
\[
d_c^+(\lambda, \nu) = -\delta^2 \nu^2 + \nu + f'(0) - \lambda; \tag{2.2}
\]
see [24] for background.

**Lemma 2.1.** (Linear spreading speed) There exists \( \delta_0 > 0 \) such that for \( \delta \in (-\delta_0, \delta_0) \), there exists a critical speed \( c_* = c_*(\delta) \), and an exponent \( \eta = \eta_*(\delta) > 0 \) for the critical speed such that the right dispersion relation (2.2) satisfies the following properties.

(i) Simple pinched double root: for \( \lambda, \nu \) near \( 0 \in \mathbb{C} \):
\[
d_c^+(\lambda, -\eta_* + \nu) = \nu^2 \sqrt{1 - 12\delta^2 f''(0)} - \lambda + O(\nu^3), \tag{2.3}
\]
with \( \sqrt{1 - 12\delta^2 f''(0)} > 0 \).

(ii) Minimal critical spectrum: if \( d_c^+(ik, -\eta_* + ik) = 0 \) for some \( \kappa, k \in \mathbb{R} \), then \( \kappa = k = 0 \).

(iii) No unstable essential spectrum: if \( d_c^+(\lambda, -\eta_* + ik) = 0 \) for some \( k \in \mathbb{R} \) and \( \lambda \in \mathbb{C} \), then \( \text{Re} \lambda \leq 0 \).

We prove Lemma 2.1 below, but first we explain how this lemma determines the essential spectrum for \( \mathcal{L}(\delta) \), the linearization about the critical front in the exponentially weighted space with critical weight determined by this lemma. The operator \( \mathcal{L}(\delta) \) has the precise form
\[
\mathcal{L}(\delta) = \omega_*(\cdot; \delta) A(\delta) \omega_*(\cdot; \delta)^{-1} = -\delta^2 \partial_x^4 + \delta^2 a_3 \partial_x^3 + (1 + \delta^2 a_2) \partial_x^2 + a_1 \partial_x + a_0,
\]
where the coefficients \( a_i(x; \delta) \) converge to limits \( a^\pm_i(\delta) \) exponentially quickly when \( x \to \pm \infty \), and are defined using the local notation \( \varpi(x) := 1/\omega_*(x; \delta) \) by the following expressions:
\[
a_3 = -4 \varpi', \quad a_2 = -6 \varpi'', \quad a_1 = c_* + 2 \varpi' - 4\delta^2 \varpi''', \quad a_0 = f'(q_*) + c_\varpi' + \varpi'' - \delta^2 \varpi''', \tag{2.4}
\]
We note that \( \varpi^{(k)}(x)/\varpi(x) = (-\eta_* k)^k \) for \( x \geq 1 \).

For such a linear operator, the essential spectrum is delimited by the two Fredholm borders, which are defined using the asymptotic dispersion relations. More precisely, the boundaries of the essential spectrum of \( \mathcal{L} \) are determined by the essential spectrum of the limiting operators \( \mathcal{L}_\pm \), obtained by sending \( x \to \pm \infty \) [18, 25]. From the construction of \( c_* \), \( \eta_* \) (see the proof of Lemma 2.1 below), we have at \( +\infty \):
\[
\mathcal{L}_+(\delta) = -\delta^2 \partial_x^2 + 4\eta_* \delta^2 \partial_x^3 + (1 - 6\delta^2 \eta_*^2) \partial_x^2. \tag{2.5}
\]
The spectrum of this constant coefficient operator is, via Fourier transform, readily seen to be marginally stable; see the red curves of Fig. 1. Notice that for \( \delta \) small, \( \eta = \eta_*(\delta) \) is the only reasonable value for
which $\mathcal{L}_+$ has a non positive zeroth-order term; any other choice of $\eta(\delta)$ will lead to spectral instability for $\mathcal{L}(\delta)$. At $-\infty$, there is no contribution from $\omega_s(\cdot; \delta)$, hence

$$L_-=A_-= -\delta^2 \partial_x^4 + \partial_x^2 + c_\ast \partial_x + f'(1)$$

has a stable spectrum, with spectral gap $f'(1) < 0$. Via the Fourier transform, this spectrum is determined by the asymptotic dispersion relation

$$d_{\ast}^c(\lambda, \nu) = -\delta^2 \nu^4 + \nu^2 + c_\ast(\delta) \nu + f'(1) - \lambda.$$

**Lemma 2.2.** (Stability on the left) If $d_{\ast}^c(\lambda, ik) = 0$ for some $k \in \mathbb{R}$, then $\Re \lambda < 0$.

Lemmas 2.1 and 2.2 together with Palmer’s theorem [30,31] imply that the essential spectrum of $\mathcal{L}(\delta)$ is marginally stable, touching the imaginary axis only at the origin [18,25]; see Fig. 1.

**Proof of Lemma 2.1.** We first look for $c_\ast, \eta_\ast > 0$ which satisfy (2.3). The polynomial $\nu \mapsto d_c(\lambda, \nu)$ at $\lambda = 0$ admits $-\eta$ as a double root if and only if $(c, \eta)$ satisfies

$$\begin{cases} 
0 = d_c^+(0, -\eta) = -\delta^2 \eta^4 + \eta^2 - c \eta + f'(0), \\
0 = \partial_\nu d_c^+(0, -\eta) = 4\delta^2 \eta^3 - 2 \eta + c. 
\end{cases}$$

(2.6)

We remove $c$ from the first equation by using the second one, and find a quadratic equation satisfied by $\eta^2$, which has roots $\pm \eta_1, \pm \eta_2$ where

$$\eta_1 := \frac{1}{|\delta| \sqrt{6}} \sqrt{1 + \sqrt{1 - 12\delta^2 f'(0)}} \sim \frac{1}{|\delta| \sqrt{3}}, \quad \eta_2 := \frac{1}{|\delta| \sqrt{6}} \sqrt{1 - \sqrt{1 - 12\delta^2 f'(0)}} \sim \sqrt{f'(0)}.$$

(2.7)

where the asymptotics hold for $\delta \to 0$. The choice $\eta_\ast = \eta_2$ and $c_\ast = 2\eta_\ast - 4\delta^2 \eta_\ast^3$ leads to

$$c_\ast(\delta) = 2\sqrt{f'(0)} - \delta^2 f'(0)^{3/2} + O(\delta^4).$$

The other double roots do not determine linear spreading speeds, as they are not pinned. Recall that a root $\nu(\lambda)$ is said to be pinned at $\lambda_0$ if it has multiplicity 2 there, and if its associated continuation $\nu_1(\lambda)$ and $\nu_2(\lambda)$ satisfies $\Re(\nu_1(\lambda)) < 0 < \Re(\nu_2(\lambda))$ when $\Re(\lambda) \in (0, +\infty)$ is large enough. This condition ensures that at $\lambda_0$, no separation can be made between unstable and stable spatial modes, thus leading to absolute spectrum there. We refer to [24, section 4.1] for details on pinned double roots. We also
point to [25, section 3.2] for the definition of absolute spectrum. We now fix \( \delta_0 = 1/\sqrt{12f'(0)} \). Then for \( |\delta| < \delta_0 \), we obtain using the expression of \( \eta_*(\delta) = \eta_2 \) that:

\[
\frac{\partial^2 d^+_e(0, -\eta_*)}{2!} = 1 - 6\delta^2\eta_*^2 = \sqrt{1 - 12\delta^2 f'(0)} > 0.
\]

Hence, \((\lambda, \nu) = (0, -\eta_*)\) is a simple double root and (2.3) is proved. Such an expansion together with the lack of unstable essential spectrum ensures that this root is pinched; see [24, Lemma 4.4]. Alternatively, Lemma 4.2 below directly proves that the root is pinched.

We briefly mention the regularity of \( \eta_* \) with respect to \( \delta \). Pushing up the development (2.7) in powers of \( \delta \), one may directly see that \( \delta \mapsto \eta_*(\delta) \) is \( C^1 \) for \( \delta \in (0, \delta_0) \). The same development ensures that \( \eta_*'(0) = 0 \), so that \( \eta_* \) is in fact \( C^1 \) on \((-\delta_0, \delta_0)\).

We now check the two remaining conditions in Lemma 2.1. We equate the polynomial \( \nu \mapsto d^+_e(\lambda, \nu) \) with its Taylor series centered at the double root \( \nu = -\eta_* \) to obtain

\[
\Re(d^+_e(\lambda, -\eta_* + ik)) = -\Re(\lambda + \Re(\sum_{j=0}^4 (ik)^j \frac{\partial^j d^+_e(\lambda, -\eta_*)}{j!})) = -\Re(\lambda - \delta^2k^4 - (1 - 6\delta^2\eta_*^2)k^2) \leq 0
\]

(2.8)

if \( \Re(\lambda) \geq 0 \), since from (2.7), we have \( 1 - 6\delta^2\eta_*^2 = \sqrt{1 - 12\delta^2 f'(0)} \geq 0 \). This proves hypothesis (iii). In case where \( \Re(\lambda) = 0 \), the inequality in (2.8) is an equality if and only if \( k = 0 \), for which we have \( d^+_e(\lambda, -\eta_*) = \Im(\lambda) \). Hence, hypothesis (ii) is proved.

\[\square\]

2.3. Preconditioner estimates

Here, we prove the estimates we will need on our preconditioner \((1 - \delta^2\partial_x^2)^{-1}\), by directly examining its Fourier symbol.

Lemma 2.3. Fix \( \eta > 0 \) sufficiently small, and fix an integer \( m \). Then, there exist constants \( \delta_0 > 0 \) and \( C = C(\delta_0, \eta) \) such that if \( |\delta| < \delta_0 \),

\[
||(1 - \delta^2\partial_x^2)^{-1}||_{L^2_{0,\eta} \rightarrow L^2_{0,\eta}} \leq C,
\]

\[
||(1 - \delta^2\partial_x^2)^{-1}||_{H^m_{0,\eta} \rightarrow H^{m+1}_{0,\eta}} \leq \frac{C}{|\delta|}.
\]

(2.9) (2.10)

Proof. By (2.1), it suffices to prove the estimates separately for \( L^2 \) and for \( L^2_{0,\eta} \) with \( \eta > 0 \) small. Since multiplication by \( e^{\eta} \) is an isomorphism from \( L^2_{0,\eta}(\mathbb{R}) \) to \( L^2(\mathbb{R}) \), to prove estimates for \((1 - \delta^2\partial_x^2)^{-1}\) on \( L^2_{0,\eta} \), it suffices to consider the inverse of the conjugate operator

\[
e^{\eta}(1 - \delta^2\partial_x^2)e^{-\eta} = 1 - \delta^2(\partial_x - \eta)^2
\]

acting on \( L^2(\mathbb{R}) \). This is the advantage of using (2.1) to separate estimates on \( L^2_{0,\eta}(\mathbb{R}) \) into estimates on \( L^2(\mathbb{R}) \) and \( L^2_{0,\eta}(\mathbb{R}) \): the conjugate operator arising from studying \((1 - \delta^2\partial_x^2)^{-1}\) on \( L^2_{0,\eta}(\mathbb{R}) \) has constant coefficients since the weight is a fixed exponential function, and so we can directly estimate its inverse using the Fourier transform. In the following, we will use the standard notation \( \langle k \rangle = (1 + k^2)^{1/2} \) several times.

Fix \( \eta \geq 0 \). By Plancherel’s theorem,

\[
||(1 - \delta^2(\partial_x - \eta)^2)^{-1}f||_{L^2} = \left\| \frac{1}{1 - \delta^2(i \cdot \eta)^2} \hat{f}(\cdot) \right\|_{L^2} \leq \sup_{k \in \mathbb{R}} \left| \frac{1}{1 - \delta^2(ik - \eta)^2} \right| ||\hat{f}||_{L^2}.
\]

Let \( \delta_0 = \min(1, 1/(\sqrt{2}\eta)) \), so that \( \delta_0^2\eta^2 \leq 1/2 \), and hence if \( |\delta| < \delta_0 \),

\[
1 + \delta^2(k^2 - \eta^2) = 1 - \delta^2\eta^2 + \delta^2k^2 \geq \frac{1}{2} + \delta^2k^2.
\]

(2.11)
Then for any $\delta$ with $|\delta| < \delta_0$, we have

$$\left| \frac{1}{1 - \delta^2(ik - \eta)^2} \right|^2 = \frac{1}{(1 + \delta^2(k^2 - \eta^2))^2 + 4k^2\delta^4\eta^2} \leq \frac{1}{(1 + \delta^2(k^2 - \eta^2))^2} \leq \frac{1}{(\frac{1}{2} + \delta^2k^2)^2} \leq C,$$

with $C$ depending only on $\delta_0$ and $\eta$, and so

$$\| (1 - \delta^2 \partial_x^2)^{-1} \|_{L^2_{\eta,\eta} \rightarrow L^2_{\eta,\eta}} \leq C.$$

Since this holds for any fixed $0 \leq \eta < 1$, in particular also for $\eta = 0$, we obtain (2.9) by combining these estimates with (2.1).

Now we prove (2.10), again by obtaining bounds on the Fourier symbol of the inverse of the conjugate operator for $\eta > 0$ and $\eta = 0$. By Plancherel’s theorem, for any fixed $0 \leq \eta < 1$, we have

$$\| (1 - \delta^2(\partial_x^2 - \eta))^{-1} f \|_{H^{m+1}} = \left\| \frac{1}{1 - \delta^2(ik - \eta)^2} \langle \cdot \rangle^{m+1} \hat{f} \right\| \leq \sup_{k \in \mathbb{R}} \left\| \frac{1}{1 - \delta^2(ik - \eta)^2} \langle k \rangle \right\| \| f \|_{H^m}.$$

Again, let $\delta_0 = \min(1, 1/(\sqrt{2}\eta))$. Then, by (2.11), we have

$$\left| \frac{1}{1 - \delta^2(ik - \eta)^2} \right|^2 = \frac{\delta^2 + \delta^2k^2}{(1 + \delta^2(k^2 - \eta^2))^2 + 4k^2\delta^4\eta^2} \leq \frac{\delta^2 + \delta^2k^2}{(\frac{1}{2} + \delta^2k^2)^2} \leq C \delta^2,$$

from which we obtain

$$\| (1 - \delta^2(\partial_x^2 - \eta))^{-1} f \|_{H^{m+1}} \leq \frac{C}{|\delta|} \| f \|_{H^m}.$$

Since this holds for $\eta \geq 0$, we obtain (2.10) from the equivalence of norms (2.1).

We now state and prove the estimates we will need on the difference between the preconditioner and the identity, $T(\delta) = (1 - \delta^2 \partial_x^2)^{-1} - 1$.

**Lemma 2.4.** Fix $\eta > 0$ sufficiently small. There exists a constant $\delta_0$ such that the mapping $\delta \mapsto T(\delta)$ is continuous from $(-\delta_0, \delta_0)$ to $\mathcal{B}(H^1_{\eta,\eta}, L^2_{\eta,\eta})$, the space of bounded linear operators from $H^1_{\eta,\eta}(\mathbb{R})$ to $L^2_{\eta,\eta}(\mathbb{R})$ with the operator norm topology.

**Proof.** As in the proof of Lemma 2.3, it suffices to establish continuity in $\delta$ of the conjugate operator $T_\eta(\delta) := (1 - \delta^2(\partial_x - \eta)^2)^{-1} - 1$ on $L^2(\mathbb{R})$ for $\eta \geq 0$ sufficiently small. For $\delta$ nonzero, we write

$$1 - \delta^2(\partial_x - \eta)^2 = \delta^2 \left( \frac{1}{\delta^2} - (\partial_x - \eta)^2 \right).$$

By standard spectral theory, we therefore see that $T_\eta(\delta)$ is continuous in $\delta$ provided $\delta$ is nonzero and $1/\delta^2$ is in the resolvent set of the operator $(\partial_x - \eta)^2$. Computing the spectrum of this operator with the Fourier transform, one readily finds that there exists a $\delta_1$ depending on $\eta$ such that this continuity holds for $0 < \delta < \delta_1$.

We now establish continuity at $\delta = 0$ via direct estimates on the Fourier multiplier.

$$\hat{T}_\eta(\delta, k) = \frac{\delta^2(ik - \eta)^2}{1 - \delta^2(ik - \eta)^2}.$$

Since we are proving continuity of $T_\eta(\delta)$ from $H^1$ to $L^2$, we gain a helpful factor of $\langle k \rangle$ — that is, it suffices to estimate $|\hat{T}_\eta(\delta, k)|/\langle k \rangle$. By (2.11), for $|\delta| < \delta_0 := \min\{\delta_1, 1/\sqrt{2}\eta\}$ we have

$$\left| \hat{T}_\eta(\delta, k) \frac{1}{\langle k \rangle} \right| = \left| \frac{\delta^2(ik - \eta)^2}{1 - \delta^2(ik - \eta)^2} \frac{1}{\langle k \rangle} \right| \leq \frac{\delta^2 \sqrt{\eta^2 - k^2}^2 + 4k^2\eta^2}{\sqrt{(1 - \delta^2(\eta^2 - k^2))^2 + 4\delta^4k^4\eta^2}} \frac{|\delta|}{(\frac{1}{2} + \delta^2k^2)^2 + 4\delta^4k^2\eta^2} \left( \delta^2 + \delta^2k^2 \right)^{1/2} \leq |\delta| \left( \frac{\delta^4\eta^4 + 4\delta^4k^4 + 2\delta^4k^2\eta^2}{(\frac{1}{2} + \delta^2k^2)^2 + 4\delta^4k^2\eta^2} \right)^{1/2}. $$
using (2.11) in the denominator. We now split the factor in the parenthesis, first estimating
\[ \frac{\delta^4 k^2 \eta^2}{\left( \frac{1}{2} + \delta^2 k^2 \right)^2 + 4 \delta^4 k^2 \eta^2} \leq \frac{\delta^4 \eta^4 + 2 \delta^4 k^2 \eta^2}{\frac{1}{4} (\delta^2 + \delta^2 k^2)} = \frac{\delta^4 \eta^4 + 2 \delta^2 k^2 \eta^2}{\frac{1}{4} (1 + k^2)} \leq C, \]
where \( C \) depends only on \( \delta_0 \) and \( \eta \). For the remaining term, we have
\[ \frac{\delta^4 k^4}{\left( \frac{1}{2} + \delta^2 k^2 \right)^2 + 4 \delta^4 k^2 \eta^2} \leq \frac{\delta^4 k^4}{\left( \frac{1}{2} + \delta^2 k^2 \right)^2 (\delta^2 k^2)} = \frac{\delta^2 k^2}{\left( \frac{1}{2} + \delta^2 k^2 \right)^2} \leq C, \]
again with constant \( C \) only depending on \( \eta \) and \( \delta_0 \). From this estimate on the Fourier symbol together with Plancherel’s theorem, we obtain
\[ ||T_\eta(\delta)||_{H^1 \rightarrow L^2} \leq C|\delta|, \]
for \(|\delta| < \delta_0\), and so in particular \( \delta \mapsto T_\eta(\delta) \) is continuous at \( \delta = 0 \), which completes the proof of the lemma.

\[ \square \]

2.4. Fredholm properties at \( \delta = 0 \)

We will further need the Fredholm properties of \( \mathcal{L}(0) \), which is the linearization in the weighted space of the classical FKPP problem \( \delta = 0 \). The classical Fisher-KPP front, at \( \delta = 0 \), may be constructed via simple phase plane methods (see [36]), and satisfies the following asymptotics
\[ q_0(x) = (ax + b)e^{-\eta_*(0)x} + O(x^2e^{-2\eta_*(0)x}), \quad x \to \infty, \]
where \( a \neq 0 \) and \( b \in \mathbb{R} \) are constants (see e.g. [19] for asymptotics of the critical Fisher-KPP front). Choosing a suitable translate \( x \mapsto q_0(x + h) \) that we still denote by \( q_0 \), we can assume that (2.12) holds with \( a = 1 \), we further note \( \mu_0 \) the corresponding value of \( b \). Direct computations lead to \( h := \frac{1}{\eta_*(0)} \log(a) \) and \( \mu_0 := \frac{b \mu}{\eta_*(0) e^{\mu}} = \frac{1}{\eta_*(0)} \log(a) + \frac{b}{a} \). In the following two lemmas, we describe the kernel, the cokernel and the range of \( \mathcal{L}(0) \). They will both be needed for the existence of the critical front \( q_*(\cdot; \delta) \) in Sect. 3, and for the control of small eigenvalues in Sect. 4. Since we only focus on properties at \( \delta = 0 \) in this section, we will sometimes denote \( \eta_*(0) \) and \( c_*(0) \) simply by \( \eta_* \) and \( c_* \) in this section.

Lemma 2.5. For \( \eta > 0 \), the operator \( \mathcal{L}(0) : H^2_{0,\eta}(\mathbb{R}) \to L^2_{0,\eta}(\mathbb{R}) \) is Fredholm with index \(-1\), with trivial kernel and with cokernel spanned by \( \varphi(x) = \omega_*(x; 0)^{-1} e^{\omega_*(0)x} q_0'(x) \).
Proof. Recall that the asymptotic operators are given by $\mathcal{L}_+(0) = \partial_x^2$ and $\mathcal{L}_-(0) = \partial_x^2 + c_*(0)\partial_x + f'(1)$. For $\eta > 0$, define the conjugate operator:

$$\mathcal{L}_+\eta(0) = \omega_{0,\eta} \mathcal{L}(0) \omega_{0,\eta}^{-1} : H^2(\mathbb{R}) \longrightarrow L^2(\mathbb{R}),$$

with asymptotic operators $\mathcal{L}_{\eta,+} = (\partial_x - \eta^2)$ and $\mathcal{L}_{\eta,-} = \mathcal{L}_-$. Since the multiplication $\omega_{0,\eta} : L^2_{\eta}(\mathbb{R}) \longrightarrow L^2(\mathbb{R})$ is an isomorphism, the Fredholm indices satisfy

$$\text{fred} \mathcal{L}_+\eta(0) = 0 = \text{fred} \mathcal{L}(0) = \text{fred} \mathcal{L}_\eta(0).$$

Then, the conjugate operator is defined on a unweighted space, and its Fredholm borders are the two oriented curves $\sigma(\mathcal{L}_{\eta,+}) = \{-k^2 + i2\eta k + \eta^2 \mid k \in \mathbb{R}\}$ and $\sigma(\mathcal{L}_{\eta,-}) = \{-k^2 + ic_*(0)k + f'(1) \mid k \in \mathbb{R}\}$, which are away from 0; see Fig. 2. This ensures that $\mathcal{L}_\eta(0)$ is Fredholm, we now compute its index $\text{fred}(\mathcal{L}_\eta(0) - \lambda)$ at $\lambda = 0$. For $\lambda$ to the right of the essential spectrum, we use Palmer’s theorem to compute the Fredholm index from the Morse indices (see e.g. [18, 25]),

$$\text{fred}(\mathcal{L}_\eta(0) - \lambda) = \dim E^u_\eta(\lambda) - \dim E^s_\eta(\lambda) = 2 - 2 = 0,$$

where $E^u_\pm$ are the unstable eigenspaces at $\pm\infty$. To prove that these spaces share the same dimension, one can take $|\lambda|$ large enough and use a standard normalization; see [14, proof of Lemma 3.1]. Then, the index decreases to $-1$ when $\lambda$ crosses $\mathcal{L}_{\eta,+}$, since the latter curve has reverse orientation, see [25]. 

Hence at $\lambda = 0$, we have shown that $\text{fred} \mathcal{L}(0) = \text{fred} \mathcal{L}_\eta(0) = -1$.

To compute the kernel, we note that

$$u \in \ker \mathcal{L}(0) \quad \text{if and only if} \quad u \in H^2_{0,\eta}(\mathbb{R}) \quad \text{and} \quad \mathcal{A}(0)\omega_*(\cdot;0)^{-1}u = 0, \quad (2.13)$$

with $\mathcal{A}(0) = \partial_x^2 + c_*(0)\partial_x + f'(q_0(x))$. Studying the asymptotic growth of the ODE $\mathcal{A}(0)u = 0$, one can construct a basis of solutions $\{q_0^\dagger, \zeta\}$, with exponential behavior at $-\infty$: $\zeta(x) \sim \exp((-\sqrt{f'(0)} - \alpha)x)$ and $q_0^\dagger(x) \sim \exp((-\sqrt{f'(0)} + \alpha)x)$ with $\alpha = \sqrt{f'(0) - f'(1)} > \sqrt{f'(0)} > 0$. See [14, proof of Lemma 2.2] for a similar construction. Furthermore, the derivative of the front has weak exponential decay at $+\infty$: $q_0^\dagger(x) \sim x\omega_q(x;0)^{-1}$. Hence, neither $\zeta$ nor $q_0^\dagger$ are sufficiently localized to satisfy the right hand condition in (2.13), so that $\ker \mathcal{L}(0) = \{0\}$. In particular, since $\mathcal{L}(0)$ has Fredholm index $-1$, this implies that $\ker(\mathcal{L}(0)^*)$ is one-dimensional.

Finally, it is easily computed that $\tilde{\mathcal{A}}(0) := \exp(\frac{\omega_q}{2}\cdot '\mathcal{A}(0)\exp(-\frac{\omega_q}{2}\cdot ')$ is self-adjoint with respect to the $L^2(\mathbb{R})$-inner product $\langle \cdot, \cdot \rangle$, so that for $v \in H^2_{0,\eta}(\mathbb{R})$ and $u \in H^2_{0,\eta}(\mathbb{R})$,

$$\langle u, \mathcal{L}^\ast(0)v \rangle = \langle \mathcal{L}(0)u, v \rangle = \langle \mathcal{A}(0)(\omega_q^{-1}u), \omega_q v \rangle = \langle \tilde{\mathcal{A}}(0)(e^{\frac{\omega_q}{2}} \omega_q^{-1}u), e^{-\frac{\omega_q}{2}} \omega_q v \rangle = \langle e^{c_r \cdot \omega_q^{-1}}u, \mathcal{A}(0)(e^{-c_r \cdot \omega_q}v) \rangle,$$

which ensures that $v \in \ker(\mathcal{L}(0)^*)$ if and only if $v \in H^2_{0,\eta}(\mathbb{R})$ and $\mathcal{A}(0)e^{-c_r(\cdot)\omega_q}(\cdot;0)v = 0$. On the first hand, notice that $\zeta$ does not contribute to $\ker(\mathcal{L}(0)^*)$: when $x \to -\infty$

$$\omega_q(x;0)^{-1}e^{c_r(\cdot)x}\zeta(x) \sim \exp((-\sqrt{f'(0)} - \alpha)x)$$

is unbounded, thus the left hand side does not belong to $H^2_{0,-\eta}(\mathbb{R})$. On the other hand, $\mathcal{L}(0)^\ast\varphi = 0$, where

$$\varphi(x) := \omega_q(x;0)^{-1}e^{c_r(\cdot)x}q_0^\dagger(x) \quad (2.14)$$

belongs to $H^2_{0,-\eta}(\mathbb{R})$, as we prove now. Using the fact that $c_*(0) = 2\eta_*(0)$ from the proof of Lemma 2.1, we see that $\varphi$ grows as a polynomial when $x \to +\infty$:

$$\varphi(x) = \omega_q(x;0)^{-1}e^{c_r(\cdot)x}\tilde{q}_0^\dagger(x) \sim e^{-\eta_*(0)x}e^{c_r(\cdot)x}\omega_q(x;0)^{-1} \sim x, \quad x \to \infty.$$  

Furthermore, $\varphi(x)$ is exponentially localized as $x \to -\infty$, since both $e^{c_r(\cdot)x}$ and $q_0^\dagger(x)$ are separately exponentially localized there, and $\omega(x;0)^{-1} \equiv 1$ for $x \leq 1$. It follows that $\varphi \in H^2_{0,-\eta}(\mathbb{R})$, as claimed. Since $\ker(\mathcal{L}(0)^*)$ is one dimensional, $\mathcal{L}^\ast(0)\varphi = 0$, and $\varphi \in H^2_{0,-\eta}(\mathbb{R})$, we conclude that $\ker(\mathcal{L}(0)^*) = \text{Span}(\varphi)$, as desired. \Halmos
Now that the kernel of $\mathcal{L}(0) : H^2_{0,\eta}(\mathbb{R}) \to L^2_{0,\eta}(\mathbb{R})$ is fully described, we can give a useful description of its range. Let $P : L^2_{0,\eta}(\mathbb{R}) \to \text{im}(\mathcal{L}(0))$ denote the orthogonal projection onto im $\mathcal{L}(0)$ with respect to the $L^2_{0,\eta}(\mathbb{R})$-inner product.

Lemma 2.6. For $\eta > 0$ small enough, the range of $\mathcal{L}(0) : H^2_{0,\eta}(\mathbb{R}) \to L^2_{0,\eta}(\mathbb{R})$ is

$$\text{im}(\mathcal{L}(0)) = \{ u \in L^2_{0,\eta}(\mathbb{R}) : \langle u, \varphi \rangle = 0 \},$$

where $\varphi$ is defined in the above Lemma 2.5 and $\langle \cdot, \cdot \rangle$ denotes the $L^2(\mathbb{R})$ inner product.

Proof. Assume that $u \in \text{im}(\mathcal{L}(0))$, so that $u = \mathcal{L}(0)\tilde{u}$ with $\tilde{u} \in H^2_{0,\eta}(\mathbb{R})$. Then $\langle u, \varphi \rangle = \langle \tilde{u}, \mathcal{L}(0)^*\varphi \rangle = 0$. To prove the reverse inclusion, write $u \in L^2_{0,\eta}(\mathbb{R})$ as $u = Pu + (1 - P)u$.

From Lemma 2.5, $\mathcal{L}(0)$ is Fredholm, hence its range is closed and $P$ is well defined. Furthermore, fred $\mathcal{L}(0) = -1$ and ker $\mathcal{L}(0) = \{0\}$, so that $1 - P$ has a one-dimensional range:

$$(1 - P)u = \alpha(u)\psi,$$

with $\psi \in L^2_{0,\eta}(\mathbb{R})$ fixed, and $\alpha : H^2_{0,\eta}(\mathbb{R}) \to \mathbb{R}$ linear. Assuming that $\langle u, \varphi \rangle = 0$, we obtain

$$0 = \langle Pu, \varphi \rangle + \langle (1 - P)u, \varphi \rangle = \langle \tilde{u}, \mathcal{L}(0)^*\varphi \rangle + \alpha(u)\langle \psi, \varphi \rangle = \alpha(u)\langle \psi, \varphi \rangle,$$

for some $\tilde{u} \in H^2_{0,\eta}(\mathbb{R})$. Hence either $\alpha(u) = 0$ or $\langle \psi, \varphi \rangle = 0$. If $\langle \psi, \varphi \rangle = 0$, then for all $v \in H^2_{0,\eta}(\mathbb{R})$, we would have $\langle v, \varphi \rangle = \langle \tilde{v}, \mathcal{L}(0)^*\varphi \rangle + \alpha(v)\langle \psi, \varphi \rangle = 0$, which is to say that $\varphi = 0$ and is a contradiction. Hence, from (2.15), we conclude $\alpha(u) = 0$, so that $u = Pu \in \text{im}(\mathcal{L}(0))$. \qed

2.5. Implicit function theorem

Our proofs of Theorems 1 and 2 rely on applying the implicit function theorem to suitably constructed maps. However, due to the singularly perturbed structure of (1.1), even after applying our regularization procedure, the associated maps to which we wish to apply the implicit function theorem are not $C^1$ in $\delta$, but instead merely continuous. We therefore rely on the following version of the implicit function theorem which requires only continuity in the parameter. This essentially follows, for instance, from the material in [23], but since the precise form we use is not stated there, we state it precisely here and adapt the proof from [23] to suit our version.

Lemma 2.7. (Implicit function theorem with continuity in parameters) Let $X$ and $Y$ be Banach spaces, and let $\Delta$ be a metric space. Let $F : X \times \Delta \to Y$ be continuous. Suppose that for each fixed $\delta \in \Delta$, $x \mapsto F(x, \delta)$ is continuously differentiable, and further that the map $(x, \delta) \mapsto D_xF(x, \delta) : X \times \Delta \to B(X, Y)$ is continuous. Suppose that for some $(x_0, \delta_0) \in X \times \Delta$, we have $F(x_0, \delta_0) = 0$ and $D_xF(x_0, \delta_0)$ has a bounded inverse. Then, there exists a neighborhood $U \times V \subset X \times \Delta$ containing $(x_0, \delta_0)$ and a function $x_*(\delta)$ such that $F(x, \delta) = 0$ for $(x, \delta) \in U \times V$ if and only if $x = x_*(\delta)$. Moreover, the map $\delta \mapsto x_*(\delta) : V \to \Delta$ is continuous, with $x_*(\delta_0) = x_0$.

Proof. Let $L = (D_xF(x_0, \delta_0))^{-1}$, and define $G : X \times \Delta \to X$ by

$$G(x, \delta) = x - LF(x, \delta).$$

We compute

$$D_xG(x, \delta) = I - L(D_xF(x, \delta)) = I - L(D_xF(x_0, \delta_0)) + L(D_xF(x_0, \delta_0) - D_xF(x, \delta)) = L(D_xF(x_0, \delta_0) - D_xF(x, \delta)),$$

and
since \( L(D_x F(x_0, \delta_0)) = I \) by construction. By continuity of \( D_x F \) and boundedness of \( L \), there exists \( 0 < \theta < 1 \) and a neighborhood \( \bar{U} \times V \) of \((x_0, \delta_0)\) such that for any \((x, \delta) \in \bar{U} \times V\), we have

\[
\|D_x G(x, \delta)\|_{\chi \to \chi} = \|L(D_x F(x_0, \delta_0) - D_x F(x, \delta))\|_{\chi \to \chi} \leq \theta.
\]

Hence for each \( \delta \in V \), the map \( x \mapsto G(x, \delta) : \bar{U} \to \chi \) is a contraction, and so by the Banach fixed point theorem, for each \( \delta \in V \) there exists \( x_*(\delta) \) such that \( G(x_*(\delta), \delta) = x_*(\delta) \). It follows from invertibility of \( L \) that \( F(x_*(\delta), \delta) = 0 \), and from continuity of \( G \) it follows that \( \delta \mapsto x_*(\delta) \) is continuous, as desired. \( \square \)

### 3. Existence of the critical front—proof of Theorem 1

Our approach is to capture the weak exponential decay at \( +\infty \) implied by the pinched double root by solving (1.2) with an ansatz

\[
q(x; \delta) = \chi_+(x) + w(x) + \chi_+(x)(\mu + x)e^{-\eta_+(\delta)x}, \quad \mu \in \mathbb{R}
\]

where \( \chi_+ \) is a smooth positive cutoff function satisfying

\[
\chi_+(x) = \begin{cases} 1, & x \geq 3, \\ 0, & x \leq 2, \end{cases}
\]

and \( \chi_-(x) = \chi_+(-x) \). For brevity, we denote by \( \psi(\mu, \delta) \) the function

\[
\psi(x; \mu, \delta) = (\mu + x)e^{-\eta_+(\delta)x}.
\]

We will require \( w \) to be exponentially localized, with a decay rate faster than \( e^{-\eta_+(\delta)x} \)—this localized piece is the core of the solution, while \( \chi_- \) and \( \chi_+ \psi \) capture the far-field behavior. Similar far-field/core decompositions have been used to construct heteroclinic solutions to pattern-forming systems in [2,21]. Inserting the ansatz (3.1) into the traveling wave equation (1.2), we get an equation

\[
\mathcal{A}_+(\delta)(\chi_- + w + \chi_+ \psi(\mu, \delta)) + \mathcal{N}(\chi_- + w + \chi_+ \psi(\mu, \delta)) = 0,
\]

where \( \mathcal{A}_+(\delta) = -\delta^2 \partial_x^4 + \delta^2 + c_1(\delta)\partial_x + f'(0) \), and \( \mathcal{N}(q) = f(q) - f'(0)q \). Since we want to require \( w \) to decay faster than the front itself, we first let \( v = \omega_+(; \delta)w \), so that (3.3) becomes

\[
0 = F(v; \mu, \delta) := \mathcal{S}(\delta)v + \omega_+(; \delta)\mathcal{A}_+(\delta)(\chi_- + \chi_+ \psi) + \omega_+(; \delta)\mathcal{N}(\chi_- + \omega_+(; \delta)^{-1}v + \chi_+ \psi),
\]

where \( \mathcal{S}(\delta) = \omega_+(; \delta)\mathcal{A}_+(\delta)\omega_+(; \delta)^{-1} \) is the conjugate operator

\[
\mathcal{S}(\delta) = -\delta^2 \partial_x^4 + \delta^2 a_3(\delta)\partial_x^2 + (1 + \delta^2 a_2(\delta))\partial_x^2 + a_1(\delta)\partial_x + \tilde{a}_0(\delta),
\]

where the coefficients \( a_i \) are given in (2.4) for \( i = 1, 2 \) or 3 while

\[
\tilde{a}_0 = f'(0) + \omega_+(; \delta)(c_1 \partial_x + \partial_x^2 - \delta^2 \partial_x^4) \omega_+(; \delta)^{-1},
\]

since we are linearizing about the unstable state \( u \equiv 0 \) rather than the front itself, which we are in the process of constructing.

Since \( \omega_+(x; \delta) = 1 \) on the support of \( \chi_- \) and \( \omega_+(x; \delta) = e^{\eta_+(\delta)x} \) on the support of \( \chi_+ \), we simplify \( F \) to

\[
F(v; \mu, \delta) = \mathcal{S}(\delta)v + \mathcal{A}_+(\delta)\chi_- + \mathcal{S}(\delta)(\mu + \cdot)\chi_+ + \omega_+(; \delta)\mathcal{N}(\chi_- + \omega_+(; \delta)^{-1}v + \chi_+ \psi).
\]

Then, we extract from \( \mathcal{N} \) terms that are linear in \( v \), together with residual terms that are \( v \)-independent. We write

\[
\omega_+(; \delta)\mathcal{N}(\chi_- + \omega_+(; \delta)^{-1}v + \chi_+ \psi) = \mathcal{N}(v; \mu, \delta) + Q(\mu, \delta)v + R(\mu, \delta)
\]

where

\[
\mathcal{N}(v; \mu, \delta) = \omega_+(; \delta)\left[ f(\chi_+ + \omega_+(; \delta)^{-1}v + \chi_+ \psi) - f(\chi_- + \chi_+ \psi) - f'(\chi_- + \chi_+ \psi)\omega_+(; \delta)^{-1}v \right],
\]

(3.5)
At $\chi_{S}v_{A}$ is exponentially localized. We group the terms together, using (3.6) to write $expanding f as a nonlinear function $G$ and thus we have immediately after equation (2.12), and where $\chi_{S}$ decomposes as the sum of a linear term, a residual term, and a nonlinear term: $F(v; \mu, \delta) = [S(\delta) + Q(\mu, \delta)]v + R(\mu, \delta) + N'(v; \mu, \delta)$, \[ (3.6) \]

where $N'(v; \mu, \delta)$ is given by (3.5), and $R(\mu, \delta) = R(\mu, \delta) + A_{+}(\delta)\chi_{-} + S(\delta)\{(\mu + \cdot)\chi_{+}\}$. At $\delta = 0$, equation (1.2) (or equivalently $F(v; \mu, 0) = 0$) is the traveling wave equation for the Fisher-KPP equation, and thus we have $F(v_{0}; \mu_{0}, 0) = 0$ where the front $q_{0}$ and the constant $\mu_{0}$ are defined immediately after equation (2.12), and where

$v_{0} = \omega_{*}(; 0)q_{0} - \chi_{-} - \chi_{+}\omega_{*}(; 0)\psi(\mu_{0}, 0)$, is exponentially localized.

To regularize the singular perturbation and enforce exponential localization of $v$, we consider

$G(v; \mu, \delta) = (1 - \delta^{2}\partial_{x}^{2})^{-1}F(v; \mu, \delta),$ as a nonlinear function $G : H_{0,\eta}^{2}(\mathbb{R}) \times \mathbb{R} \times \mathbb{R} \to L_{0,\eta}^{2}(\mathbb{R})$, for $\eta > 0$ sufficiently small.

**Lemma 3.1.** Fix $\eta > 0$ sufficiently small. There exists $\delta_{0} > 0$ such that the map

$(v, \mu, \delta) \mapsto G(v, \mu, \delta) : H_{0,\eta}^{2}(\mathbb{R}) \times \mathbb{R} \times (-\delta_{0}, \delta_{0}) \to L_{0,\eta}^{2}(\mathbb{R})$ is well defined, continuously differentiable in $v$ and $\mu$, and continuous in $\delta$. Moreover, the map

$(v; \mu, \delta) \mapsto \partial_{(v, \mu)}G(v, \mu, \delta) : H_{0,\eta}^{2}(\mathbb{R}) \times \mathbb{R} \times (-\delta_{0}, \delta_{0}) \to \mathcal{B}(H_{0,\eta}^{2}(\mathbb{R}) \times \mathbb{R}, L_{0,\eta}^{2}(\mathbb{R}))$ is continuous.

**Proof.** We use (3.6) to write $G$ as

$G(v; \mu, \delta) = (1 - \delta^{2}\partial_{x}^{2})^{-1}S(\delta)v + (1 - \delta^{2}\partial_{x}^{2})^{-1}[Q(\mu, \delta)v + R(\mu, \delta) + N'(v; \mu, \delta)]$. \[ (3.7) \]

Using the fact that $f$ is smooth and that $H_{0,\eta}^{2}(\mathbb{R})$ is a Banach algebra, one readily finds by Taylor expanding $f$ where it appears in $N$ and $Q$ that if $v \in H_{0,\eta}^{2}(\mathbb{R})$, then $||Q(\mu, \delta)v + N'(v; \mu, \delta)||_{L_{0,\eta}^{2}} < \infty.$

We group the terms $A_{+}(\delta)\chi_{-}$ and $R(\mu, \delta)$ together, observing that since derivatives of $\chi_{-}$ are compactly supported, for $x \leq -3$ we have $A_{+}(\delta)\chi_{-} = f'(0)\chi_{-}$, and so writing

$A_{+}(\delta)\chi_{-} + R(\mu, \delta) = (A_{+}(\delta)\chi_{-} - f'(0)\chi_{-}) + \omega_{*}[f(\chi_{-} + \chi_{+}) - f'(0)\chi_{+}]$, the term $(A_{+}(\delta)\chi_{-} - f'(0)\chi_{-})$ is compactly supported, while for the other term we have by Taylor expansion

$||\omega_{*}[f(\chi_{-} + \chi_{+}) - f'(0)\chi_{+}]||_{L_{0,\eta}^{2}} \leq C||\omega_{*}(\chi_{+})^{2}||_{L_{0,\eta}^{2}} < \infty.$

The remaining term $S(\delta)[(\mu + \cdot)\chi_{+}]$ in $R(\mu, \delta)$ is strongly localized by the choice of the far-field ansatz: $\chi_{-}(x)$ is identically zero for $x$ large, and for $x$ large the fact that $(\eta_{*}(\delta), c_{*}(\delta))$ solve the system (2.6) implies that every term in $S(\delta)$ has at least two derivatives in it, so $S(\delta)[(\mu + \cdot)\chi_{+}] \equiv 0$ on the support of $\chi_{+}$, and the only terms that remain are compactly supported commutator terms. Hence,

$||R(\mu, \delta)||_{L_{0,\eta}^{2}} \leq ||R(\mu, \delta) + A_{+}(\delta)\chi_{-}||_{L_{0,\eta}^{2}} + ||S(\delta)[(\mu + \cdot)\chi_{+}]||_{L_{0,\eta}^{2}} < \infty.$
Together with (2.9) of Lemma 2.3, this implies that the second term of (3.7) is in $L^2_{0,\eta} (\mathbb{R})$, and so to check that $G$ is well defined, it only remains to estimate the first term in (3.7). For this term, we use the specific form of $S(\delta)$, given in (3.4), to write

$$(1 - \delta^2 \partial^2_x)^{-1} S(\delta) = \partial^2_x + \delta^2 (1 - \delta^2 \partial^2_x)^{-1} [a_3 \partial^3_x + a_2 \partial^2_x] + (1 - \delta^2 \partial^2_x)^{-1} (a_1 \partial_x + a_0).$$

(3.8)

Since $a_3$ and $a_2$ are smooth, constant outside of fixed compact set, and bounded uniformly in $\delta$, we have

$$||a_3 \partial^3_x + a_2 \partial^2_x||_{H^2_{0,\eta} \to H^1_{0,\eta}} \leq C.$$

Combining this with estimate (2.10) of Lemma 2.3, we obtain

$$||\delta^2 (1 - \delta^2 \partial^2_x)^{-1} (a_3 \partial^3_x + a_2 \partial^2_x)||_{H^2_{0,\eta} \to L^2_{0,\eta}} \leq C|\delta|.$$  

(3.9)

The other terms in (3.8) are readily seen to be uniformly bounded in $\delta$ as operators from $H^2_{0,\eta} (\mathbb{R})$ to $L^2_{0,\eta} (\mathbb{R})$ for $\delta$ sufficiently small, from which we conclude that $G$ is well defined.

Since the nonlinearity $f$ is smooth, differentiability of $G$ in $v$ follows readily from the fact that $H^2_{0,\eta} (\mathbb{R})$ is a Banach algebra whose norm controls the $L^\infty$ norm. Differentiability in $\mu$ is also readily attainable from smoothness of $f$ and the exponential localization of our ansatz. The preconditioner plays little role in these arguments—when treating the residual terms or the nonlinearity, we do not need to use the preconditioner at all to obtain smoothness in $v$ and $\mu$.

The residual terms as well as the nonlinearity are also readily seen to be continuous in $\delta$. The main subtlety is to handle the term $$(1 - \delta^2 \partial^2_x)^{-1} S(\delta),$$ which we write as

$$(1 - \delta^2)^{-1} S(\delta) = (\partial^2_x + a_1 \partial_x + a_0) + \delta^2 (1 - \delta^2 \partial^2_x)^{-1} (a_3 \partial^3_x + a_2 \partial^2_x) + T(\delta) (a_1 \partial_x + a_0),$$

where $T(\delta) = (1 - \delta^2 \partial^2_x)^{-1} - 1$. The operator $\partial^2_x + a_1 (x, \delta) \partial_x + a_0 (x, \delta)$ is continuous in $\delta$ from $H^2_{0,\eta}$ to $L^2_{0,\eta}$ since the coefficients are smooth and uniformly bounded in $\delta$. The second term is continuous in $\delta$ by (3.9), and the last term is continuous in $\delta$ by Lemma 2.4. Continuity of $\partial_{(v,\mu)} G(v; \mu, \delta)$ proceeds analogously.

With the appropriate regularity of $G$ in hand, we now aim to solve near $(v_0, \mu_0, 0)$ using the implicit function theorem. The linearization about this solution in $v$ is given by

$$\partial_v G(v_0; \mu_0, 0) = S(0) + Q(\mu_0, 0) + \partial_v \mathcal{N}(v_0; \mu_0, 0) = S(0) + f'(q_0) - f'(0) = \mathcal{L}(0).$$

From Lemma 2.5, $\partial_v G(v_0; \mu_0, 0)$ is Fredholm with index $-1$, so that the joint linearization $\partial_{(v,\mu)} G(v_0; \mu_0, 0)$ is Fredholm index 0 by the Fredholm bordering lemma [35, Lemma 4.4]. We show that in fact, the joint linearization has full range and, hence, is invertible. We do this by computing an appropriate projection on the cokernel $\mathcal{L}(0)^* = \text{Span}(\varphi)$, and so we first record useful asymptotics of $\varphi$.

**Lemma 3.2.** The function $\varphi$ defined in Lemma 2.5 satisfies

$$\lim_{x \to \infty} \varphi'(x) = -\eta_*(0) \neq 0.$$  

(3.10)

**Proof.** We start by extracting asymptotics of $q'_0$ and $q''_0$, and then use the formula $\varphi(x) = \omega_*(x; 0)^{-1} e^{-\eta_*(0)x} q'_0(x)$ to obtain the corresponding asymptotics of $\varphi'$. The asymptotics of $q'_0$ and $q''_0$ may be formally obtained by differentiating the asymptotics $q_0(x) \sim (\mu_0 + x) e^{-\eta_*(0)x}$. However, strictly speaking these asymptotics do not necessarily control the behavior of the derivatives, and so we rigorously justify this computation below.

Since the Fisher-KPP equation is translation invariant, $p_0 := q'_0$ solves the linearized equation

$$(\partial^2_x + c_*(0) \partial_x + F(q_0(x))) p_0 = 0.$$
To make this equation autonomous, we couple it to the equation $q_0'' + c_* q_0' + f(q_0) = 0$, and write the corresponding system in 4 “unknowns” $(Q_1, Q_2, Q_3, Q_4) = (q_0, q_0', p_0, p_0')$ as

$$
\begin{pmatrix}
Q_1' \\
Q_2' \\
Q_3' \\
Q_4'
\end{pmatrix} = \begin{pmatrix}
0 & 1 & 0 & 0 \\
-c_*(0) Q_2 - f(Q_1) & Q_2 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-c_*(0) Q_4 - f'(Q_1) Q_3, \\
\end{pmatrix}
\begin{pmatrix}
Q_1 \\
Q_2 \\
Q_3 \\
Q_4
\end{pmatrix}.
\quad (3.11)
$$

Notice that $(Q_1^0, Q_2^0, Q_3^0, Q_4^0) := (q_0, q_0', q_0', q_0'')$ solves this system by construction. Furthermore, the phase plane construction of $q_0$ implies that $q_0(x), q_0'(x) \to 0$ as $x \to \infty$, which in turn by the equation $q_0'' + c_0 q_0' + f(q_0) = 0$ implies that also $q_0''(x) \to 0$ as $x \to \infty$. Hence, the solution $(Q_1^0, Q_2^0, Q_3^0, Q_4^0)$ lies in the stable manifold of the origin. The linearization of (3.11) at the origin is

$$
\begin{pmatrix}
Q_1' \\
Q_2' \\
Q_3' \\
Q_4'
\end{pmatrix} = \begin{pmatrix}
0 & 1 & 0 & 0 \\
-\eta_*^2(0) - 2 \eta_* (0) & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & -\eta_*^2(0) - 2 \eta_* (0) & 0 & 0
\end{pmatrix}
\begin{pmatrix}
Q_1 \\
Q_2 \\
Q_3 \\
Q_4
\end{pmatrix}.
\quad (3.12)
$$

The block matrix $\begin{pmatrix} 0 & 1 \\ -\eta_*^2(0) & -2 \eta_* (0) \end{pmatrix}$ has a repeated eigenvalue $-\eta_*(0)$, which forms a Jordan block with eigenvector $e_0 = \begin{pmatrix} 1 \\ -\eta_* (0) \end{pmatrix}$ and generalized eigenvector $e_1 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$. The expressions of $e_0$ and $e_1$ can be either computed directly, or hinted from the companion structure of the bloc matrix. Solutions to (3.11) in the stable manifold of the origin therefore have expansions

$$
\begin{pmatrix}
Q_1(x) \\
Q_2(x) \\
Q_3(x) \\
Q_4(x)
\end{pmatrix} = \begin{pmatrix}
c_1 e_0 e^{-\eta_*(0)x} + c_2 (e_0 x + e_1) e^{-\eta_*(0)x} \\
0 \\
0 \\
c_3 e_0 e^{-\eta_*(0)x} + c_4 (e_0 x + e_1) e^{-\eta_*(0)x}
\end{pmatrix} + O(x^2 e^{-2 \eta_*(0)x}).
\quad (3.13)
$$

In particular, since $(Q_1^0, Q_2^0, Q_3^0, Q_4^0) = (q_0, q_0', q_0'', q_0''')$ is such a solution, we see that $q_0'$ and $q_0''$ have expansions of the form

$$
q_0'(x) = (\alpha x + \beta) e^{-\eta_*(0)x} + O(x^2 e^{-2 \eta_*(0)x}), \quad q_0''(x) = (\tilde{\alpha} x + \tilde{\beta}) e^{-\eta_*(0)x} + O(x^2 e^{-2 \eta_*(0)x})
$$

for some constants $\alpha, \beta, \tilde{\alpha}$, and $\tilde{\beta}$. The coefficients $c_1$ and $c_2$ are fixed by the first line of (3.13), and the fact that $Q_1^0(x) = q_0(x) \sim (\mu_0 + x) e^{-\eta_*(0)x}$. Using the expansions of $q_0'$ and $q_0''$ together with the second, third and fourth lines of (3.13) allow to compute first $\alpha, \beta$ then $c_3, c_4$ and finally $\tilde{\alpha}, \tilde{\beta}$. Altogether, we obtain the following asymptotic, that coincide with a formal differentiation of $q_0$:

$$
q_0'(x) = (1 - \eta_*(0) \mu_0 - \eta_*(0)x) e^{-\eta_*(0)x} + O(x^2 e^{-2 \eta_*(0)x}), \\
q_0''(x) = (\eta_*(0)^2 \mu_0 - 2 \eta_*(0) + \eta_*(0)^2 x) e^{-\eta_*(0)x} + O(x^2 e^{-2 \eta_*(0)x}).
$$

Note for $x \geq 1$, we have $\varphi(x) = e^{-\eta_*(0)x} e^{\eta_*(0)x} q_0(x) = e^{\eta_*(0)x} q_0'(x)$, using the fact that $c_0 = 2 \eta_*(0)$, Hence for $x \gg 1$, we have after a short computation

$$
\varphi' = \eta_*(0) e^{\eta_*(0)x} q_0'(x) + e^{\eta_*(0)x} q_0''(x) = -\eta_*(0) + O(x^2 e^{-\eta_*(0)x}),
$$

as desired. $\square$

We now use these asymptotics of $\varphi'$ to show that $\partial_{(v, \mu)} G(v_0; \mu_0, 0)$ is invertible.

**Lemma 3.3.** The joint linearization $\partial_{(v, \mu)} G(v_0; \mu_0, 0) : H^2_0, \eta (\mathbb{R}) \times \mathbb{R} \to L^2_0, \eta (\mathbb{R})$ is invertible.
Proof. To show that \( \partial_{(\nu, \mu)} G(v_0; \mu_0, 0) \) is invertible, we show that \( \partial_{\mu} G(v_0; \mu_0, 0) \) is linearly independent from the range of \( \mathcal{L}(0) \). More precisely, \( \partial_{\mu} G(v_0; \mu_0, 0) \), by the strictest definition, is a linear operator from \( \mathbb{R} \) to \( L^2_{0, \eta}(\mathbb{R}) \), but this linear operator may be naturally identified with \( \partial_{\mu} G(v_0; \mu_0, 0) \cdot 1 \in L^2_{0, \eta}(\mathbb{R}) \), and we show that this function does not lie in the range of \( \mathcal{L}(0) \). From Lemma 2.6, it is enough to obtain \( \langle \partial_{\mu} G(v_0; \mu_0, 0), \varphi \rangle \neq 0 \). After a short computation, one finds

\[
\partial_{\mu} G(v_0; \mu_0, 0) = S(0)\chi_+ + (f'(q_0) - f'(0))\chi_+ = \mathcal{L}(0)\chi_+.
\]

We compute \( \langle \mathcal{L}(0)\chi_+, \varphi \rangle \) via integration by parts, with the goal being to move \( \mathcal{L}(0) \) onto the other side of the inner product as its adjoint and exploit the fact that \( \mathcal{L}(0)^* \varphi = 0 \). However, we must be careful since \( \varphi \) and \( \chi_+ \) are not localized at \( \infty \), and in fact there is one boundary term from integration by parts which does not vanish. We see this by writing

\[
\int_{\mathbb{R}} \chi'' \varphi \, dx = -\int_{\mathbb{R}} \chi' \varphi' \, dx = \int_{\mathbb{R}} \chi + \varphi'' - [\chi + \varphi']_{-\infty}^{\infty} = \langle \chi_+, \varphi'' \rangle - \varphi'(\infty) = \langle \chi_+, \varphi'' \rangle + \eta_*(0),
\]

We use Lemma 3.2 in the final equality to replace \( \varphi'(\infty) \) with \( -\eta_*(0) \). Recalling that \( \mathcal{L}(0) = \partial_x^2 + f'(q_*) \) for \( x \geq 1 \), we obtain

\[
\langle \mathcal{L}(0)\chi_+, \varphi \rangle = \langle \chi_+, \mathcal{L}(0)^* \varphi \rangle + \eta_*(0) = \eta_*(0) = \frac{c_*(0)}{2} > 0,
\]

which concludes the proof. \( \square \)

Proof of Theorem 1. Since \( G(v_0; \mu_0, 0) = 0, \partial_{(\nu, \mu)} G(v_0; \mu_0, 0) \) is invertible by Lemma 3.3, and \( G \) has the requisite regularity by Lemma 3.1, by the implicit function theorem (Lemma 2.7), there exist \( v(\delta) \in H^2_{0, \eta}(\mathbb{R}) \) and \( \mu(\delta) \in \mathbb{R} \) depending continuously on \( \delta \) near \( \delta = 0 \) such that \( G(v(\delta); \mu(\delta), \delta) = 0 \). By construction of \( G \), this implies that

\[
q_*(x; \delta) := \chi_-(x) + \omega_*(x; \delta)^{-1}v(x; \delta) + \chi_+(x)(\mu(\delta) + x)e^{-\eta_*(\delta)x}
\]

solves (1.2). The claim that \( q_* (\cdot, \delta) - q_* (\cdot; 0) = q_0 \) uniformly in space follows from the form of this ansatz, together with the fact that \( H^2_{0, \eta}(\mathbb{R}) \) is continuously embedded in \( L^\infty(\mathbb{R}) \). \( \square \)

4. Small eigenvalues

Having established existence of the critical front, we are now ready to study the point spectrum of the linearization about the front. Here, we show that there is no eigenvalue in a neighborhood of the origin, and in particular no resonance embedded in the essential spectrum at the origin. For this, we follow [32]: apply a Lyapunov-Schmidt reduction to construct a scalar function which vanishes at the eigenvalues, in a similar manner to the Evans function.

Throughout this section, we set \( \Omega(\delta) := \{0\} \cup (C \setminus \sigma_{ess}(\mathcal{L}_\delta)) \), and restrict to \( \lambda \in \Omega(\delta) \). Then \( \lambda \) is off the negative real axis, so that the principal value of \( \gamma := \sqrt{\lambda} \) is defined by \( \text{Re} \gamma \geq 0 \).

Proposition 4.1. There exists \( \delta_0, \gamma_0 > 0 \) and a function \( E : (-\delta_0, \delta_0) \times B(0, \gamma_0) \to \mathbb{C} \), continuous in \( \delta \) and analytic in \( \gamma \) such that for all \( \gamma \in \Omega(\delta) \), the eigenvalue problem

\[
(\mathcal{L}(\delta) - \gamma^2)u = 0
\]

admits a bounded solution \( u \) if and only if \( E(\delta, \gamma) = 0 \). Furthermore, \( E(0, 0) \neq 0 \). In particular, there exists \( \gamma_1, \delta_1 > 0 \) such that for all \( \delta \in (-\delta_1, \delta_1) \), \( \mathcal{L}(\delta) \) has no eigenvalues on \( B(0, \gamma_1^2) \cap \Omega(\delta_1) \).

For any fixed \( \delta \neq 0 \), notice that (4.1) is a linear, non-degenerate ODE with smooth (i.e. \( C^\infty \) with respect to \( x \in \mathbb{R} \)) coefficients, so that any solution \( u \) belongs to \( C^\infty(\mathbb{R}) \). Furthermore, such a solution admits exponential expansions at \( \pm \infty \) (see the proof of Lemma 4.2 hereafter), so that when \( \gamma^2 \) is to the right of the essential spectrum, \( u \) is bounded if and only if it lies in \( H^1(\mathbb{R}) \), which is to say it is an
eigenfunction. We will therefore consider bounded solutions from this point forward: for $\gamma^2$ to the right of the essential spectrum, they correspond with eigenfunctions, while at $\gamma = 0$ they capture resonances of $\mathcal{L}(\delta)$.

We first show that a bounded solution of (4.1) decomposes into two parts: a uniformly localized part and a slowly decaying part, whose rate is $\gamma$-close to 0.

**Lemma 4.2.** Near $(\delta, \gamma) = (0, 0)$, the roots of the polynomial $\nu \mapsto d^+_{c_*}(\gamma^2, -\eta_* + \nu)$ satisfy:

$$
\nu_1 = -\frac{1}{|\delta|} + O(1), \quad \nu_2 = -\gamma + O(\delta \gamma + \gamma^2), \quad \nu_3 = \gamma + O(\delta \gamma + \gamma^2), \quad \nu_4 = \frac{1}{|\delta|} + O(1),
$$

where each $O$ is taken as $\delta$ and $\gamma$ goes to 0.

In particular, there exists $\delta_0 > 0$, $\gamma_0 > 0$ and $\eta > 0$ such that for all $\delta \in (-\delta_0, \delta_0)$, and $\gamma \in B(0, \gamma_0)$ with $\gamma^2 \in \Omega(\delta)$, a bounded and smooth solution $u$ of (4.1) decomposes as

$$
u(x) = w(x) + \beta \chi_+(x)e^{\nu x},
$$

where $w \in H^2_{0,n}(\mathbb{R})$ and $\beta \in \mathbb{C}$. In this decomposition, $\chi_+$ is the cutoff function (3.2).

**Proof.** The claimed expansions of the four roots is purely technical and is postponed to the end of the proof. Rewrite (4.1) as a first-order ODE in $\mathbb{R}^4$:

$$
\partial_x U = M(x; \delta, \gamma),
$$

where $U = (u, u', u'', u^{(3)})^T$. The matrix $M$ converges toward $M_\pm(\delta, \gamma)$ when $x \to \pm \infty$, with an exponential rate which is independent of $\delta$ and $\gamma$. The eigenvalues of this asymptotic matrices $M_\pm$ are the roots of the dispersion relations $d^\pm_{c_*}(\gamma^2, -\eta_* + \cdot)$. It is standard that with such a convergence rate, these eigenvalues determine the behavior of $U$ at $\pm \infty$; see for example [14, proof of Lemma 2.2].

More precisely, the behavior at $+\infty$ is the following. For $\gamma \neq 0$, the four roots are distinct, so that the exponential behavior is ensured: $U(x) \sim \sum_{i=1}^4 c_i(U)e^{\nu_i x}$ when $x \to +\infty$, with $c_i(U, \delta, \gamma)$ are vectors that does not depend on $x$. As $\gamma^2 \notin \sigma_{es}(\mathcal{L}(\delta))$, the two small roots satisfy $\text{Re} \nu_2(\delta, \gamma) < 0 < \text{Re} \nu_3(\delta, \gamma)$, so that a bounded $U$ has exactly the claimed form. At $\gamma = 0$, the two small roots merge to form a Jordan block. The proof in the above reference adapts, and we have the following expansion: $U(x) \sim c_1(U)e^{\nu_1 x} + c_2(U) + c_3(U)x + c_4(U)e^{\nu_4 x}$ when $x \to +\infty$. The terms $c_2(U) + c_3(U)x$ correspond to the 2-dimensional center space at $\gamma = 0$, with the weakly growing term $c_4(U)x$ a consequence of the presence of the Jordan block. Once again the claimed decomposition is satisfied.

At $-\infty$, the four roots of $d^-_{c_*}(\gamma^2, -\eta_* + \cdot)$ are distinct, and bounded away from 0 with spectral gap uniform in $(\delta, \gamma)$. Then, the expansion $U(x) \sim \sum_{i=1}^4 c_i(U)e^{\nu_i x}$ holds at $x \to -\infty$, so that any bounded $U$ lies in $H^2(\mathbb{R}_-)$. Hence, the claimed decomposition holds. For an alternative argument not relying on the dynamical systems view of exponential expansions, see Remark 4.7.

We now establish the expansions of the roots by applying the implicit function theorem to $d^-_{c_*}$. From the choice of $\eta_*$ (see also (2.5)), we have

$$
g_0(\delta, \gamma, \nu) := d^+_{c_*}(\gamma^2, -\eta_* + \nu) = -\delta^2 \nu^4 + 4 \eta_* \delta^2 \nu^3 + (1 - 6 \delta^2 \eta_*^2) \nu^2 - \gamma^2.
$$

To avoid any $\delta$ singularity, we get rid of the $\delta^2$ in the dominant term by changing variables $\mu := \nu|\delta|:

$$
g_1(\delta, \gamma, \mu) := \delta^2 g_0(\delta, \gamma, \frac{\mu}{|\delta|}) = -\mu^4 + 4 \eta_* |\delta| \mu^3 + (1 - 6 \delta^2 \eta_*^2) \mu^2 - \gamma^2 \delta^2.
$$

At $(\delta, \gamma) = (0, 0)$, this reduces to $g_1(0, 0, \mu) = -\mu^4(\mu - 1)(\mu + 1)$. Applying the implicit function theorem to the simple root $-1$, we construct a root $\mu_1(\delta, \gamma)$ for $g_1(\delta, \gamma, \cdot)$ whose derivatives can be computed iteratively by differentiating the relation $g_1(\delta, \gamma, \mu_1(\delta, \gamma)) = 0$. One can show by induction that any pure derivative in $\gamma$ is null: $\partial^k_\gamma \mu_1(0, 0) = 0$ for $k \in \mathbb{N}$. This ensures that the Taylor expansion has the form

$$
\mu_1(\delta, \gamma) = -1 - \delta \frac{\partial_\delta g_1(0, 0, -1)}{\partial_\mu g_1(0, 0, -1)} - \gamma \frac{\partial_\gamma g_1(0, 0, -1)}{\partial_\mu g_1(0, 0, -1)} + O(\delta^2 + \delta^2) = -1 + O(\delta).
$$
Coming back to the original variable, we define \(\nu_1(\delta, \gamma) = \mu_1(\delta, \gamma)/|\delta|\), which satisfies the claimed expansion. The same steps can be applied to define \(\mu_4(\delta, \gamma) = 1 + O(\delta)\), which in turn leads to \(\nu_4(\delta, \gamma)\) as claimed.

To unfold the double root at \(\mu = 0\), we change variables once again to \(\nu = \gamma \sigma\):

\[
g_2(\delta, \gamma, \sigma) = \frac{g_3(\delta, \gamma, \gamma \sigma)}{\gamma^2} = -\delta^2 \gamma^2 \sigma^4 + 4\eta_2 \delta^2 \gamma \sigma^3 + (1 - 6\delta^2 \eta_2^2)\sigma^2 - 1.
\]

At \((\delta, \gamma) = (0, 0)\), this reduces to \(g_2(0, 0, \sigma) = (\sigma - 1)(\sigma + 1)\). Applying the implicit function theorem once again gives rise to

\[
s_2(\delta, \gamma) = -1 + O(\delta + \gamma), \quad s_3(\delta, \gamma) = 1 + O(\delta + \gamma),
\]

which in turns leads to the claimed estimates on \(\nu_2(\delta, \gamma) = \gamma s_2(\delta, \gamma)\) and \(\nu_3(\delta, \gamma) = \gamma s_3(\delta, \gamma)\).

As in the existence of the critical front, our problem is singular at \(\delta = 0\). Hence, we apply the same preconditioner: when \(\delta\) is small, (4.1) is equivalent to

\[
(1 - \delta^2 \partial_x^2)^{-1} (\mathcal{L}(\delta) - \gamma^2) w = 0.
\]

We now use the decomposition of Lemma 4.2 to separate out the localized part of our problem from the far-field behavior, which will allow us to make use of the Fredholm properties on weighted spaces of Sect. 2.4. In the following, for \(\delta \in (-\delta_0, \delta_0)\) and \(\gamma \in B(0, \gamma_0)\) we let

\[
A(\delta, \gamma, \eta) = \{w \mid w \in H^2_{0, \eta}(\mathbb{R}), \beta \in \mathbb{R}\},
\]

denote the set where the ansatz obtained above holds.

**Lemma 4.3.** There exist positive constants \(\delta_0, \gamma_0\) and \(\eta\) such that if \(\delta \in (-\delta_0, \delta_0)\), \(\gamma \in B(0, \gamma_0)\) and \(w \in A(\delta, \gamma, \eta)\), then \((1 - \delta^2 \partial_x^2)^{-1} (\mathcal{L}(\delta) - \gamma^2) w \in L^2_{0, \eta}(\mathbb{R})\).

**Proof.** First, \((1 - \delta^2 \partial_x^2)^{-1}(\mathcal{L}(\delta) - \gamma^2) w\) belongs to \(L^2_{0, \eta}(\mathbb{R})\) by the choice of the preconditioner, using the same regularization effect we observed in (3.8). Then, as \(\chi_+\) is smooth, vanishes on \((-\infty, 2)\) and is constant on \((3, +\infty)\), it only remains to show that \((\mathcal{L}(\delta) - \gamma^2)e^{\nu x} \in L^2_{0, \eta}(\mathbb{R}_+)\). For \(x \geq 1\), almost all coefficients of \(\mathcal{L}\) are constants, see (2.4), hence we compute

\[
(\mathcal{L}(\delta) - \gamma^2)e^{\nu x} = (\mathcal{L}(\delta) - \mathcal{L}_+(\delta))e^{\nu x} + (\mathcal{L}_+(\delta) - \gamma^2)e^{\nu x} = (f'(q_*(x; \delta)) - f'(0)) e^{\nu x} + d_{e_+}(\gamma^2, \nu_2 - \eta_*) e^{\nu x},
\]

Recall that the polynomial \(\nu \mapsto d_+^\nu(\lambda, -\eta_* + \nu)\) is the dispersion relation of \(\mathcal{L}_+(\delta) - \lambda\), i.e. that \(d_+^\nu(\gamma^2, -\eta_* + \nu_2) = \mathcal{L}_+(\delta) - \gamma^2\), and that \(\mathcal{L}_+(\delta)\) is the asymptotic operator (2.5). From the definition of \(\nu_2(\delta, \gamma)\), \(d_+^\nu(\gamma^2, -\eta_2 + \nu_2) = 0\), hence for \(x \geq 1\):

\[
(\mathcal{L}(\delta) - \gamma^2)e^{\nu x} = (f'(q_*(x)) - f'(0)) e^{\nu x} = f''(0) q_*(x; \delta) e^{\nu x} + O \left( e^{\nu x} q_*(x; \delta)^2 \right).
\]

The right hand side belongs to \(L^2_{0, \eta}(\mathbb{R})\) as long as \(\eta\) satisfies

\[
-\eta_* + Re \nu_2(\delta, \gamma) < -\eta.
\]

We can take a smaller \(\gamma_0\) than in Lemma 4.2, so that \(\sup_{\delta, \gamma} \{ -\eta_*(\delta) + Re \nu_2(\delta, \gamma)\} < 0\), which then allows to fix \(\eta > 0\) so that (4.3) is satisfied for all \(\delta \in (-\delta_0, \delta_0)\) and \(\gamma \in B(0, \gamma_0)\). This concludes the proof. \(\square\)

We can now use Lemma 2.6 to decompose our problem into a part which belongs to \(\text{im}(\mathcal{L})(0)\) and a complementary part. Recall that \(P : L^2_{0, \eta}(\mathbb{R}) \rightarrow \text{im}(\mathcal{L}(0))\) and that \(\varphi\) allows to describe \(\text{im}(\mathcal{L}(0))\). Fix \(\delta \in (-\delta_0, \delta_0)\), and \(\gamma \in B(0, \gamma_0) \cap \Omega(\delta)\). If \(u\) is a bounded solution of (4.1) then \((w, \beta) \in H^2_{0, \eta}(\mathbb{R}) \times \mathbb{C}\) defined in Lemma 4.2 solves:

\[
\begin{cases}
P (1 - \delta^2 \partial_x^2)^{-1} (\mathcal{L}(\delta) - \gamma^2)(w + \beta h) = 0, \\
((1 - \delta^2 \partial_x^2)^{-1} (\mathcal{L}(\delta) - \gamma^2)(w + \beta h), \varphi) = 0,
\end{cases}
\]

(4.4)
where \( h(x) = \chi_+(x) e^{\nu_2(\gamma)x} \). Reciprocally, if \((w, \beta) \in H^2_{0, \eta}(\mathbb{R}) \times \mathbb{C} \) satisfies (4.4), then \( w = w + \beta h \) is bounded and satisfies (4.1). We write the first equation as

\[
0 = \mathcal{F}(w, \beta; \gamma, \delta) := P (1 - \delta^2 \partial^2_x)^{-1} (\mathcal{L}(\delta) - \gamma^2)(w + \beta h).
\]

and solve it with the implicit function theorem. We will then use the second equation to define \( E(\delta, \gamma) \).

**Lemma 4.4.** For \( \eta > 0 \) sufficiently small, the map

\[
\mathcal{F} : H^2_{0, \eta}(\mathbb{R}) \times \mathbb{C} \times B(0, \gamma_0) \times (-\delta_0, \delta_0) \to \text{Im} \mathcal{L}(0)
\]

is continuously differentiable in \( w \) and \( \beta \), analytic in \( \gamma \), and continuous in \( \delta \). Moreover, the map

\[
(w, \beta; \gamma, \delta) \mapsto \partial_w \mathcal{F}(w, \beta; \gamma, \delta) : H^2_{0, \eta}(\mathbb{R}) \times \mathbb{C} \times B(0, \gamma_0) \times (-\delta_0, \delta_0) \to B(H^2_{0, \eta}(\mathbb{R}), \text{Im} \mathcal{L}(0))
\]

is continuous.

**Proof.** Note that \( \mathcal{F} \) is linear in \( w \) and \( \beta \), so differentiability is automatic provided the linear part in \( w \) is well defined, which is guaranteed here by Lemma 4.3. For the continuity of \( \partial_w \mathcal{F}(w, \beta; \gamma, \delta) \), we write

\[
(1 - \delta^2 \partial^2_x)^{-1} \mathcal{L}(\delta) = \partial^2_x + a_1 \partial_x + a_0 + \delta^2 (1 - \delta^2 \partial^2_x)^{-1} (a_3 \partial_x^3 + a_2 \partial^2_x) + T(\delta)(a_1 \partial_x + a_0).
\]

We see by Lemmas 2.3 and 2.4 that \( (1 - \delta^2 \partial^2_x)^{-1} \mathcal{L}(\delta) \) is a well-defined family of bounded operators from \( H^2_{0, \eta} \) to \( L^2_{0, \eta} \), depending continuously on \( \delta \). This is of course preserved when we compose with the projection \( P \). We write the other term in the linearization in \( w \) as

\[
\gamma^2 (1 - \delta^2 \partial^2_x)^{-1} w = \gamma^2 w + \gamma^2 T(\delta) w,
\]

which is again continuous in \( \gamma \) and \( \delta \) as a bounded linear operator from \( H^2_{0, \eta} \) to \( L^2_{0, \eta} \) by Lemma 2.4. Hence, \( \partial_w \mathcal{F} \) is continuous. Analyticity of \( \mathcal{F} \) in \( \gamma \) follows as in [32, Proposition 5.11]. For the continuity of \( \mathcal{F} \) with respect to \( \delta \), it only remains to look at the terms associated to \( h \). We rewrite

\[
(\mathcal{L}(\delta) - \gamma^2) h = [\mathcal{L}_+(\delta), \chi_+] e^{\nu_2(\delta, \gamma)} + (\mathcal{L}(\delta) - \mathcal{L}_+(\delta)) e^{\nu_2(\delta, \gamma)},
\]

using the fact that \( (\mathcal{L}_+(\delta) - \gamma^2) e^{\nu_2(\delta, \gamma)} = 0 \), and where \( [\mathcal{L}_+(\delta), \chi_+] = \mathcal{L}_+(\delta) \chi_+ - \chi_+ \mathcal{L}_+(\delta) \) is the commutator between these operators. In this form, we recognize that \( [\mathcal{L}_+(\delta), \chi_+] \) and \( (\mathcal{L}(\delta) - \mathcal{L}_+(\delta)) \) are both differential operators with exponentially localized coefficients, with rate uniform in \( \delta \) for \( \delta \) small. By Lemma 4.2, \( e^{\nu_2(\delta, \gamma)x} \) is continuous in \( \gamma \) and \( \delta \) for each fixed \( x \), and the uniform localization of \( [\mathcal{L}_+(\delta), \chi_+] \) and \( (\mathcal{L}(\delta) - \mathcal{L}_+(\delta)) \) guarantees that these terms are continuous in \( \delta \) in \( L^2_{0, \eta} \) for \( \eta \) small. In fact, since \( h \) is a smooth function, we see that \( \delta \mapsto (\mathcal{L}(\delta) - \gamma^2) h \) is in particular continuous from \((-\delta_1, \delta_1)\) to \( H^1_{0, \eta} \).

Taking into account the preconditioner, we write

\[
(1 - \delta^2 \partial^2_x)^{-1} (\mathcal{L}(\delta) - \gamma^2) h = (\mathcal{L}(\delta) - \gamma^2) h + T(\delta)(\mathcal{L}(\delta) - \gamma^2) h.
\]

By Lemma 2.4, this term is continuous in \( \delta \), as desired. \( \square \)

**Corollary 4.5.** For \( \gamma, \delta \) sufficiently small, and for \( \beta \in \mathbb{C} \), there is a family of solutions \( w \) to (4.5) which have the form

\[
w(\beta; \gamma, \delta) = \beta \tilde{w}(\gamma, \delta).
\]

Moreover, any solution to (4.5) with \( \gamma, \delta \) small has this form.

**Proof.** We begin with the trivial solution \( \mathcal{F}(0, 0; 0, 0) = 0 \). The linearization in \( w \) about this trivial solution is \( \partial_w \mathcal{F}(0, 0; 0, 0) = P \mathcal{L}(0) \), which is invertible by Lemmas 2.5 and 2.6. Together with Lemma 4.4, this implies that we can solve near this trivial solution with the implicit function theorem (Lemma 2.7), obtaining a unique solution \( w(\beta; \gamma, \delta) \) in a neighborhood \( \mathcal{U} \) of \((0, 0; 0, 0)\). Since (4.5) is linear in \( w \) and \( \beta \), by uniqueness any solution in this neighborhood can be written as

\[
w(\beta; \gamma, \delta) = \beta \tilde{w}(\gamma, \delta)
\]
for some function \( \tilde{w}(\gamma, \delta) \in H^2_{0,\eta}(\mathbb{R}) \). To see this, note that if for some fixed \( \gamma, \delta \) small we have another solution \((w_0, \beta_0)\) to \((4.5)\) which does not a priori have this form, by dividing by a sufficiently large constant \( K(||w_0||_{H^2_{\beta,\eta}}) \) we get another solution which belongs to the neighborhood \( \mathcal{U} \) where we have solved with the implicit function theorem, and so we conclude that

\[
\frac{w_0}{K(||w_0||_{H^2_{\beta,\eta}}, \beta)} = \frac{\beta}{K(||w_0||_{H^2_{\beta,\eta}}, \beta)} \tilde{w}(\gamma, \delta),
\]

and hence the solution \((w_0, \beta_0)\) in fact has the form \((4.6)\), as claimed. \( \square \)

Having solved the first equation in \((4.4)\) with the implicit function theorem, we now insert this solution \(w(\beta; \gamma, \delta) = \beta \tilde{w}(\gamma, \delta)\) into the second equation, so that \((4.4)\) has a solution if and only if

\[
0 = E(\delta, \gamma) := \langle (1 - \delta^2 \partial_x^2)^{-1}(\mathcal{L}(\delta) - \gamma^2)\tilde{w}(\gamma, \delta) + h, \varphi \rangle.
\] (4.7)

Note that we have been able to eliminate the \( \beta \) dependence in this equation, since all terms in this equation are linear in \( \beta \) by Corollary 4.5. Since the projection \( P \) played no role in the proof of Lemma 4.4, the same argument shows that \( E \) is continuous in both of its arguments.

**Lemma 4.6.** The function \( E: (-\delta_0, \delta_0) \times B(0, \gamma_0) \to \mathbb{C} \) is continuous in both arguments, and analytic in \( \gamma \) for fixed \( \delta \).

**Proof.** It only remains to prove that \( E(0, 0) \neq 0 \). From \((4.7)\), we see that

\[
E(0, 0) = \langle \mathcal{L}(0)(\tilde{w}(0, 0) + \chi_+), \varphi \rangle.
\]

Since \( \tilde{w}(0, 0) \in H^2_{0,\eta}(\mathbb{R}) \), we have

\[
\langle \mathcal{L}(0)\tilde{w}(0, 0), \varphi \rangle = \langle \tilde{w}(0, 0), \mathcal{L}(0)^*\varphi \rangle = 0.
\]

Hence, we obtain

\[
E(0, 0) = \langle \mathcal{L}(0)\chi_+, \varphi \rangle = \eta_*(0) \neq 0,
\]

by the computation in the proof of Lemma 3.3. \( \square \)

**Remark 4.7.** Rather than using the spatial dynamics approach to exponential expansions outlined in the proof of Lemma 4.2 to show directly that eigenfunctions have the form \((4.2)\), one can instead show that for \( \delta \neq 0 \), \((\mathcal{L}(\delta) - \gamma^2) \): \( H^2(\mathbb{R}) \to L^2(\mathbb{R}) \) is invertible if \( E(\delta, \gamma) \neq 0 \) and \( \gamma^2 \) is to the right of the essential spectrum of \( \mathcal{L}(\delta) \), using an argument adapted from [32]. Indeed, if \( \gamma^2 \) is to the right of the essential spectrum, then \( \mathcal{L}(\delta) - \gamma^2 \) is Fredholm with index 0 on \( L^2(\mathbb{R}) \), and in particular has closed range, so to invert this operator on \( L^2(\mathbb{R}) \), it suffices to solve \((\mathcal{L}(\delta) - \gamma^2)u = g \) for \( g \) in the dense subspace \( L^2_{0,\eta}(\mathbb{R}) \). The fact that the range of \( \mathcal{L}(\delta) - \gamma^2 \) is closed then implies \( \mathcal{L}(\delta) - \gamma^2 \) is surjective, and hence invertible since it is Fredholm of index 0. The open mapping theorem then implies the inverse is bounded, so \( \gamma^2 \) will be in the resolvent set of \( \mathcal{L}(\delta) \). To solve \((\mathcal{L}(\delta) - \gamma^2)u = g \) for \( g \in L^2_{0,\eta}(\mathbb{R}) \), one looks for solutions in the form \((4.2)\), and finds that \((w, \beta)\) solve the system \((4.4)\) but with \((0, 0)^T\) on the right hand side replaced by \((Pg, (g, \varphi))^T\). We can always solve the first equation with the implicit function theorem, and we can solve the second equation precisely when \( E(\delta, \gamma) \neq 0 \), as claimed. At \( \gamma = 0 \), we lose Fredholm properties on \( L^2(\mathbb{R}) \), but the fact that \( E(\delta, 0) \neq 0 \) implies there is no solution to \( \mathcal{L}(\delta)u = 0 \) of the form \( u = w + \beta \chi_+ \) for \( w \) exponentially localized, and this is actually all that is needed in [4] to prove nonlinear stability. One could additionally use a modified far-field/core decomposition at \( \gamma = 0 \) to prove that all bounded solutions to \( \mathcal{L}(\delta)u = 0 \) have the form \( u = w + \beta \chi_+ \).
Fig. 3. Three regions for the study of the point spectrum. The function $E(\delta, \gamma)$ from Sect. 4 rules out point spectrum in the dashed ball centered at the origin, together with a potential eigenvalue at the origin. Proposition 5.1 excludes point spectrum to the right of the dashed curve. Finally, the green region to the right contains no point spectrum provided $\delta$ is small enough, see Proposition 5.2.

5. Large and intermediate eigenvalues—proof of Theorem 2

Here, we conclude the study of the point spectrum. We first exclude any large unstable point spectrum, using mostly that the operator is sectorial.

**Proposition 5.1.** There exists a compact set $K \subset \mathbb{C}$ such that for all $\delta$ small, any eigenvalue $\lambda$ of $L(\delta)$ with $\text{Re} \lambda \geq 0$ lies in $K$. More precisely, an eigenvalue $\lambda$ satisfies:

$$\text{Re} \lambda \leq \| b(\cdot; \delta) \|_{\infty}, \quad |\text{Im} \lambda| \leq c_* \sqrt{\| b(\cdot; \delta) \|_{\infty} - \text{Re} \lambda},$$

where $b(\cdot; \delta) = f'(q_*(\cdot; \delta))$ is uniformly bounded.

**Proof.** We work with $\delta \in (-\delta_0, \delta_0)$, with $\delta_0$ small enough so that Theorem 1 applies. Assume that $\lambda \in \mathbb{C}$ and $\psi \in H^4(\mathbb{R})$ satisfy $L(\delta)\psi = \lambda \psi$. Coming back to the unweighted operator $A(\delta) = \omega_*(\cdot; \delta)^{-1} L(\delta) \omega_*(\cdot; \delta)$, defined by (1.4), we obtain

$$A(\delta)\phi = \lambda \phi$$

with $\phi = \omega_*(\cdot; \delta)^{-1} \psi \in H^4(\mathbb{R})$. Up to a scalar multiplication, we can assume that $\| \phi \|_{L^2(\mathbb{R})} = 1$. Now we take the $L^2(\mathbb{R})$-inner product of (5.1) with $\phi$, and pass into Fourier space, to obtain that:

$$\int_{\mathbb{R}} (-\delta^2 \xi^4 - \xi^2 + ic_* \xi)|\hat{\phi}(\xi)|^2d\xi + \int_{\mathbb{R}} f'(q_*(x))|\phi(x)|^2dx = \lambda,$$

(5.2)

where $\mathcal{F}u = \hat{u}$ denotes the Fourier transform of a function $u$. We let $I_0 = \int_{\mathbb{R}} f'(q_*(x))|\phi(x)|^2dx$ denote the zeroth-order term. Then, real and imaginary parts of equation (5.2) give

$$\text{Re} \lambda - I_0 = -\int_{\mathbb{R}} (\delta^2 \xi^4 + \xi^2)|\hat{\phi}(\xi)|^2d\xi, \quad \text{Im} \lambda = c_* \int_{\mathbb{R}} \xi|\hat{\phi}(\xi)|^2d\xi.$$

Hence, by the Cauchy–Schwartz inequality:

$$0 \leq (\text{Im} \lambda)^2 \leq c_*^2 \| \hat{\phi} \|_{L^2}^2 \int_{\mathbb{R}} \xi^2|\hat{\phi}(\xi)|^2d\xi \leq c_*^2 \int_{\mathbb{R}} (\delta^2 \xi^4 + \xi^2)|\hat{\phi}(\xi)|^2d\xi = c_*^2 (I_0 - \text{Re} \lambda).$$

(5.3)

Note that $b(\cdot; \delta)$ is uniformly bounded with respect to $\delta \in (-\delta_0, \delta_0)$, since this holds for $q_*(\cdot; \delta)$ from Theorem 1, and since $f'$ is continuous.
Observe that $|I_0| \leq \|b\|_\infty \|\phi\|_T^2$. Inserting this into (5.3) leads to the claimed bounds on $\text{Re} \lambda$ and $\text{Im} \lambda$. These bounds together with the requirement $\text{Re} \lambda \geq 0$ define a compact set $K$. \hfill $\square$

We now conclude the proof of Theorem 2 by excluding the possibility of any eigenvalues in the intermediate region; see Fig. 3.

**Proposition 5.2.** For each $\delta_0 > 0$ sufficiently small, there exists $r(\delta_0) > 0$ with $r(\delta_0) \to 0$ as $\delta_0 \to 0$ such that for all $\delta$ with $|\delta| < \delta_0$, the operator $\mathcal{L}(\delta)$ has no eigenvalues in $\{\text{Re} \lambda \geq 0\} \setminus B(0, r(\delta_0))$.

**Proof.** Suppose to the contrary that there exists a sequence $\delta_n \to 0$ with corresponding eigenvalues $\lambda_n$ bounded away from the origin, with $\text{Re} \lambda_n \geq 0$, and with eigenfunctions $u_n$. We normalize the eigenfunctions so that $\|u_n\|_{H^2} = 1$ for all $n$. By Proposition 5.1, these eigenvalues all belong to the compact set $K$. By compactness, we extract a subsequence along which $\lambda_n \to \lambda_\infty$ for some $\lambda_\infty \in K$, and $\lambda_\infty \neq 0$, since the sequence was bounded away from the origin. We now show that in this limit, $\lambda_\infty$ is an eigenvalue for $\mathcal{L}(0)$ with $\text{Re} \lambda \geq 0$, contradicting the spectral stability of this operator.

These eigenfunctions solve $(\mathcal{L}(\delta_n) - \lambda_n)u_n = 0$. We precondition by applying $(1 - \delta_n^2 \partial_x^2)^{-1}$ to both sides of this equation, obtaining

$$\left[\partial_x^2 + a_1(\cdot, \delta_n)\partial_x + a_0(\cdot, \delta_n) + E_1(\delta_n) + E_2(\delta_n) - \lambda_n - \lambda_n T(\delta_n)\right] u_n = 0,$$

where

$$E_1(\delta_n) = \delta_n^2 (1 - \delta_n^2 \partial_x^2)^{-1}(a_3(\cdot, \delta_n)\partial_x^2 + a_2(\cdot, \delta_n)\partial_x^2), \quad E_2(\delta_n) = T(\delta_n)(a_1(\cdot, \delta_n)\partial_x + a_0(\cdot, \delta_n)).$$

We relate this to the KPP linearization $\mathcal{L}(0)$ by rewriting (5.4) as

$$(\mathcal{L}(0) - \lambda_\infty)u_n = -E_1(\delta_n)u_n - E_2(\delta_n)u_n + E_3(\delta_n)u_n + (\lambda_n - \lambda_\infty)u_n + \lambda_n T(\delta_n)u_n =: f_n$$

where

$$E_3(\delta_n) = (a_1(\cdot, 0) - a_1(\cdot, \delta_n))\partial_x + (a_0(\cdot, 0) - a_0(\cdot, \delta_n)).$$

It follows from Lemma 2.3 and the fact that the coefficients $a_j(\cdot; \delta)$ are uniformly bounded in $\delta$ that

$$\|E_1(\delta_n)u_n\|_{L^2} \leq C\delta_n \|u_n\|_{H^2} = C\delta_n.$$

Similarly, by Lemma 2.4, we see that $E_2(\delta_n)u_n \to 0$ and $\lambda_n T(\delta_n)u_n \to 0$ in $L^2$ as $n \to \infty$, since $\lambda_n$ and $u_n$ are uniformly bounded in $n$. Lastly, by the construction of the exponential weights, the fact that $q_\delta(\cdot; 0)$ converges uniformly to $q_\delta(\cdot; 0)$ as $\delta \to 0$ by Theorem 1, and the assumption that $\|u_n\|_{H^2}$ is uniformly bounded, we see that also $E_3(\delta_n)u_n \to 0$ in $L^2$ as $n \to \infty$. Hence, $f_n$ converges to zero in $L^2$ as $n \to \infty$.

Since $\lambda_\infty$ is not in the spectrum of $\mathcal{L}(0)$, we can invert $(\mathcal{L}(0) - \lambda_\infty)$ to write

$$u_n = (\mathcal{L}(0) - \lambda_\infty)^{-1}f_n,$$

from which we observe that $u_n \to 0$ in $H^2(\mathbb{R})$ as $n \to \infty$ by boundedness of the resolvent operator. This is a contradiction since we have normalized $u_n$ so that $\|u_n\|_{H^2} = 1$. \hfill $\square$

**Proof of Theorem 2.** By Proposition 4.1, there exist $\gamma_1, \delta_1 > 0$ so that for all $\delta \in (-\delta_1, \delta_1)$, $\mathcal{L}(\delta)$ has no eigenvalues in $B(0, \gamma_1^2)$ and also has no resonance at $\lambda = 0$. By Proposition 5.2, there exists a $\delta_0 > 0$ so for all $\delta \in (-\delta_0, \delta_0)$, $\mathcal{L}(\delta)$ has no eigenvalues in $\{\text{Re} \lambda \geq 0\} \setminus B(0, \frac{\gamma_1}{2})$. Hence for all $\delta \in (-\delta_0, \delta_0)$, $\mathcal{L}(\delta)$ has no eigenvalues in $\{\text{Re} \lambda \geq 0\}$, as desired. \hfill $\square$
