Calabi–Yau structures for multiplicative preprojective algebras

Tristan Bozec, Damien Calaque, Sarah Scherotzke

Abstract
In this paper we deal with Calabi–Yau structures associated with (differential graded versions of) deformed multiplicative preprojective algebras, of which we provide concrete algebraic descriptions. Along the way, we prove a general result that states the existence and uniqueness of negative cyclic lifts for non-degenerate relative Hochschild classes.

1 Introduction

Given a quiver $Q$, that is an oriented graph, one may consider the preprojective algebra associated to $Q$ over some field $k$. It can be defined as a quotient of the path algebra $kQ$ of the double quiver $Q$, obtained by adjoining to each edge $e : i \to j$ between two vertices $i$ and $j$ a reverse edge $e^* : j \to i$. We quotient by a single relation

$$\mu = \sum_{e \in Q} [e, e^*],$$

a signed combination of 2-cycles in $Q$. Originally introduced by Gelfand–Ponomarev \cite{GelfandPonomarev} (see also \cite{IyuduKontsevichVlassopoulos}) in a strictly algebraic context, the preprojective algebra turns out bearing a strong geometric significance. It may indeed be understood as the algebraic structure underlying the cotangent to the moduli of representations of $Q$ (see \cite{Crawley-BoeveyShaw} for a fully precise statement). Its representations correspond to the $0$-fiber of the moment map associated to the linear group acting by conjugation at each vertex. This fact has been extensively used by Lusztig \cite{Lusztig}, and later Nakajima \cite{Nakajima}, to geometrically realize quantum groups and their representations, in particular through the definition of lagrangian subvarieties of symplectic quiver moduli.

Multiplicative variants of these preprojective algebras have been introduced by Crawley-Boevey and Shaw \cite{Crawley-BoeveyShaw} in the course of their study of the Deligne–Simpson problem. It is defined by performing a quotient by

$$\prod_{e \in Q} (1 + ee^*)(1 + e^*e)^{-1}$$

of an appropriate localization of $kQ$. These variants turn out to naturally appear in various areas such as character varieties \cite{Crawley-BoeveyShaw, FernándezHerscovich, IyuduKontsevichVlassopoulos, Shoikhet}, local systems on Riemann surfaces and perverse sheaves on nodal curves \cite{Crawley-BoeveyShaw, CullerShalen, CadmanKarp, Shoikhet}, or integrable systems \cite{FernándezHerscovich} among others. The geometric framework in which multiplicative quiver varieties seem to be better studied is the one of quasi-hamiltonian reduction and group-valued moment maps from \cite{Van den Bergh, Van den Bergh}, as shown by Van den Bergh \cite{Van den Bergh, Van den Bergh}.

Multiplicative preprojective algebras fit both into the quasi-hamiltonian formalism and into its non-commutative analogue as developped by Van den Bergh in \cite{Van den Bergh}. In the first case, group-valued moment maps and the quasi-hamiltonian formalism have a nice interpretation within the framework of shifted symplectic geometry of \cite{Givental}, in terms of lagrangian morphisms and derived lagrangian intersections (see \cite{CotangentBundle, Verdier}).

Using the non-commutative analogue of quasi-hamiltonian formalism, one obtains that multiplicative preprojective algebras come equipped with double quasi-Poisson structures \cite{Van den Bergh}. Furthermore, Fernández and Herscovich have recently proved in \cite{FernándezHerscovich} that double quasi-Poisson structures give rise to pre-Calabi–Yau structures in the sense of Iyudu–Kontsevich–Vlassopoulos \cite{IyuduKontsevichVlassopoulos}, extending a similar result from \textit{loc. cit.} for double Poisson structures.

In the same way as shifted Poisson structures in the sense of \cite{ClineParshallScott, EtingofGinzburg} arise on the source of morphisms equipped with a lagrangian structure \cite{FernándezHerscovich} (actually, shifted Poisson structures are conjectured to be equivalent to lagrangian thickenings), it is expected that pre-Calabi–Yau structures in the sense of \cite{IyuduKontsevichVlassopoulos} often (if not always) arise on the target of Calabi–Yau morphisms in the sense of \cite{Crawley-BoeveyShaw}.

Hinging on these observations, our goal is to directly construct Calabi–Yau structures on appropriate algebraic objects, and get back the usual lagrangian morphisms associated with group-valued moment maps on moduli spaces. Namely, we do the following:

\footnote{We would like to warn the reader that pre-Calabi–Yau structures in \textit{loc. cit.} are different from the ones considered e.g. in \cite{Crawley-BoeveyShaw, IyuduKontsevichVlassopoulos} (the latter being non-commutative pre-symplectic structures, rather than non-commutative Poisson structures).}
We first study a Calabi–Yau structure on $k[x^\pm 1]$, seen as the multiplicative analog of $k[x]$. Using this Calabi-Yau structure, we obtain using \cite{7} a 1-shifted symplectic structure on moduli of perfect complexes. We show that restricting to the moduli of representations we recover the usual 1-shifted symplectic structure on the adjoint quotient which is crucial in the derived symplectic interpretation of the quasi-hamiltonian formalism;

(2) We give a 1-Calabi-Yau structure on cospans which allow us to retrieve standard lagrangian correspondences when applying the moduli of objects functor $\text{Perf}$. We recover in particular the lagrangian correspondence that was shown in \cite{25} to underlie the fusion product from \cite{1};

(3) We give a relative 1-Calabi–Yau structure on the algebraic counterpart of the group-valued moment map. This is done via a gluing procedure called fusion.

(4) Via pushouts of Calabi-Yau cospans, we obtain a 2-Calabi-Yau structure on the differential graded multiplicative preprojective algebra, defined in Theorem 4.11. The zero truncation of the differential graded multiplicative preprojective algebra is the original multiplicative preprojective algebra.

Description of the paper

In section 2, we provide a short recollection on Calabi–Yau structures, after \cite{7}. We also show that, in the case of smooth dg-categories sitting in degree 0, the required cyclic lift of the non-degenerate relative Hochschild class, in the definition of a Calabi–Yau structure on a morphism, automatically exists and is unique. This extends to the relative case a result of \cite{29}, and is of independent interest, see Theorem 2.5.

Section 3 uses this result to produce 1-Calabi–Yau structures on $k[\mathbb{G}_m] = k[x^\pm 1]$ and the cospan defined by $k[x^\pm 1] \amalg k[y^\pm 1] \to k[x^\pm 1, y^\pm 1] \leftarrow k[z^\pm 1]$, denoted by $\mathcal{F}$ in this introduction only. In each case we define explicit Hochschild classes that we prove to be non-degenerate. Thanks to section 2, these admit a unique cyclic lift. We also study evaluation morphisms $k[x^\pm 1] \to k$.

In section 4, using the Calabi-Yau structures of the previous section, we show in Theorem 4.8 that the multiplicative moment map is 1-Calabi-Yau. The quiver $A_2 = \bullet \to \bullet$ serves as a building block. Again, this structure is made explicit and proven to be non-degenerate “by hand”, whereas its cyclic lift exists thanks to section 2. The cospan $\mathcal{F}$ studied earlier then serves in a gluing process (a.k.a. fusion) to extend our result to arbitrary quivers. Pushouts along evaluation morphisms yield a 2-Calabi-Yau structure on a dg-algebra whose 0-truncation is the classical multiplicative preprojective algebra, c.f. Theorem 4.11.

Finally, section 5 justifies our choices of Hochschild classes defining Calabi–Yau structures. We prove that when taking $\text{Perf}$, we retrieve standard symplectic structures. Namely, the 1-shifted symplectic structure on $\text{Perf}_{k[x^\pm 1]}$ matches the one on the derived loop stack $\mathcal{L}\text{Perf}_k$. We also prove that the Calabi–Yau structure on $\mathcal{F}$ corresponds to a particular gluing of the boundaries of the pair-of-pants. We conjecture that the structures we get on our dg-variants of multiplicative preprojective algebras yield standard quasi-hamiltonian structures on multiplicative quiver varieties.

Related works

In \cite{3}, Bezrukavnikov and Kapranov prove that certain triangulated categories of microlocal complexes on nodal curves have a Calabi–Yau property, which roughly corresponds to the existence of an almost Calabi–Yau structure according to our terminology. However, it is not clear if it admits an actual Calabi–Yau (i.e. cyclic) lift. In loc. cit. the authors mention
a dg-version of the multiplicative preprojective algebra and expect that it is a Calabi–Yau
dg-algebra. Our results show that this is indeed true. This expectation was motivated by the
existence of an equivalence of abelian categories between microlocal sheaves on nodal curves
with rational components on the one side, and modules over the multiplicative preprojective
algebra on the other side. They could not conclude, because it is not known if a similar
equivalence holds for the dg-version of the multiplicative preprojective algebra.

A similar approach is considered by Shende and Takeda in their work [28] on Calabi–Yau
structures of topological Fukaya categories. It is possible that, following some suggestions
from [28, §7.4 & §7.5], one could potentially recover some of our existence results in a
geometric way, as opposed to the explicit algebraic approach of the present paper. The
obtained Calabi–Yau structures would then deserve to be compared with ours. The last
section of our paper provides tools for such a comparison, that would then essentially rely
on the fact that both approaches are compatible with some gluing/fusion process; though,
the comparison for the $A_2$ building bloc remains to be dealt with.

Yeung [37, §5.5] also exhibits a Calabi–Yau structure on the multiplicative preprojective
dg-algebra associated with a star-shaped quiver. It seems that his Calabi–Yau structure
differs from ours, unless one goes through some adic completion (see Remark 3.2).

Finally, Kaplan and Schedler [17] show that the multiplicative preprojective (non dg)
algebra is Calabi–Yau whenever the quiver is connected and contains an unoriented cycle.
They conjecture that it is still Calabi–Yau for every quiver that is connected and not Dynkin;
they also conjecture that, under these assumptions, the multiplicative preprojective algebra
and its dg-version are quasi-isomorphic (and they prove this for quivers satisfying a “strong
free product property”). This is consistent with our result, which only concerns the dg-
version, but holds without any assumption on the quiver.

2 Calabi–Yau structures

2.1 Recollection on Calabi–Yau structures
Along this paper, we use the same notation and terminology as in [6]. We recall briefly the
most important information. Note also that in this paper $k$ is a field of characteristic zero.

We denote by $\text{Mod}_k$ the category of cochain complexes over $k$. A $\text{dg-category}$ is a $\text{Mod}_k$-
enriched category and the category of dg-categories with dg-functors is denoted by $\text{Cat}_k$.
We refer to [18, 30] for a detailed introduction to dg-categories and their homotopy theory.

If $\mathcal{M}$ is a model category, we will write $\mathcal{M}$ for the corresponding $\infty$-category obtained
by localizing along weak equivalences.

We use the notation “$\text{Map}$” to distinguish the space of $\infty$-categorical morphisms from
the set of 1-categorical morphisms, for which we use the notation “$\text{Hom}$”. The underlined
versions designate their enriched counterparts (unless otherwise specified, the enrichment
is over complexes). If a category has a symmetric monoidal structure which is closed, we
use upper case letters for the internal enrichment, i.e. $\text{HOM}$ and $\text{MAP}$, for categories and
$\infty$-categories, respectively.
Recall the Hochschild chains functor

\[ \text{HH} : \text{Cat}_k \longrightarrow \text{Mod}_k, \quad \mathcal{A} \mapsto \mathcal{A} \overset{\mathcal{L}}{\otimes} \mathcal{A}^{\text{op}}, \]

where \( \mathcal{A}^e := \mathcal{A} \otimes \mathcal{A}^{\text{op}} \). We write \( \text{HH}_i(\mathcal{A}) \) for the \((-i)\)-th cohomology of \( \text{HH}(\mathcal{A}) \). Dually, \( \text{HH}^i(\mathcal{A}) \) is defined as the \( i \)-th cohomology of \( \mathbb{R}\text{Hom}_{\mathcal{A}^e}(\mathcal{A}, \mathcal{A}) \).

Hochschild chains carry a mixed structure, which is given in the standard explicit model by Connes’s \( B \)-operator. The negative cyclic complex of \( \mathcal{A} \), denoted by \( \text{HC}^-(\mathcal{A}) \), is defined as the homotopy fixed points of \( \text{HH}(\mathcal{A}) \) with respect to the mixed structure; it comes with a natural transformation \((-)^\# : \text{HC}^- \Rightarrow \text{HH} \). As before, \( \text{HC}^i(\mathcal{A}) \) stands for the \((-i)\)-th cohomology of \( \text{HC}^-(\mathcal{A}) \).

Recall the inverse dualizing functor \((-)^\vee : \text{Mod}_{\mathcal{A}^e} \longrightarrow \text{Mod}_{\mathcal{A}^{\text{op}}} \) that is given as follows: for a right \( \mathcal{A}^e \)-module \( M \), and an object \( a \in \text{Ob}(\mathcal{A}^{\text{op}} \otimes \mathcal{A}) \),

\[ M^\vee(a) := \mathbb{R}\text{Hom}_{\text{Mod}_{\mathcal{A}^e}}(M \circ \tau, \mathcal{A}^e(a, -)) . \]

where \( \tau \) is the anti-involution \( \tau : \mathcal{A}^e \overset{\sim}{\longrightarrow} (\mathcal{A}^e)^{\text{op}} \) such that \( \mathcal{A} \circ \tau = \mathcal{A}^{\text{op}} \).

A dg-category \( \mathcal{A} \) is smooth if \( \mathcal{A} \) is a perfect \( \mathcal{A}^e \)-module. For smooth dg-categories, we have the following equivalences

\[ (-)^\flat : \text{HH}(\mathcal{A}) \overset{\sim}{\longrightarrow} \mathbb{R}\text{Hom}_{\text{Mod}_{\mathcal{A}^e}}(\mathcal{A}^\vee, \mathcal{A}) \]

and

\[ \mathbb{R}\text{Hom}_{\text{Mod}_{\mathcal{A}^e}}(\mathcal{A}, \mathcal{A}) \simeq \mathcal{A}^\vee \overset{\mathcal{L}}{\otimes} \mathcal{A}^e . \]

**Definition 2.1.** Let \( \mathcal{A} \) be a smooth dg-category.

1. A class \( c : k[n] \rightarrow \text{HH}(\mathcal{A}) \) such that \( c^\flat : \mathcal{A}^\vee[n] \rightarrow \mathcal{A} \) is an equivalence is called non-degenerate. Such a non-degenerate Hochschild class is called an almost \( n \)-Calabi–Yau structure on \( \mathcal{A} \).

2. A \( n \)-Calabi–Yau structure on \( \mathcal{A} \) is a class \( c : k[n] \rightarrow \text{HC}^-(\mathcal{A}) \) such that \( c^\# \) is non-degenerate.

We now recall (relative) Calabi–Yau structures on morphisms and cospans of dg-categories, following Brav–Dyckerhoff [7] and Toën [31, §5.3].

**Definition 2.2.** Let \( \mathcal{A} \overset{f}{\longrightarrow} \mathcal{C} \overset{g}{\longleftarrow} \mathcal{B} \) be a cospan of smooth dg-categories.

1. An almost \( n \)-Calabi–Yau structure on this cospan is the data of a homotopy commuting diagram

\[
\begin{array}{ccc}
k[n] & \longrightarrow & \text{HH}(\mathcal{B}) \\
\downarrow c_A & & \downarrow \\
\text{HH}(\mathcal{A}) & \longrightarrow & \text{HH}(\mathcal{C})
\end{array}
\]

such that \( c_A \) and \( c_B \) are non-degenerate in the sense of Definition 2.1(1), and such that the homotopy \( \text{HH}(f)(c_A) \sim \text{HH}(g)(c_B) \) is non-degenerate in the following sense: the
induced (homotopy) commuting square

\[
\begin{array}{ccc}
C^\vee[n] & \xrightarrow{g^\vee} & (B^\vee[n]) \otimes_{B^e} C^e \\
\downarrow f^\vee & & \downarrow g \otimes id \\
(A^\vee[n]) \otimes_{A^e} C^e & \xrightarrow{f \otimes id} & C
\end{array}
\]

is cartesian.

(2) An \(n\)-Calabi–Yau structure on the cospan is a homotopy commuting diagram

\[
\begin{array}{ccc}
k[n] & \xrightarrow{c_A} & HC^- (B) \\
\downarrow c_B & & \downarrow \\
HC^- (A) & \xrightarrow{c} & HC^- (C)
\end{array}
\]

such that the image under \((-)^{\natural}\) is an almost \(n\)-Calabi–Yau structure.

(3) If \(A = \emptyset\) then we call these (almost) \(n\)-Calabi–Yau structures on the morphism \(g\).

Recall that \(n\)-Calabi–Yau cospans do compose: after [7, Theorem 6.2], the non-degeneracy property is preserved under composition.

We finally note that whenever \(A = B = \emptyset\), an \(n\)-Calabi–Yau structure on \(\emptyset \rightarrow C \leftarrow \emptyset\) is the same as an \((n + 1)\)-Calabi–Yau structure on \(C\). In particular, the push-out of two \(n\)-Calabi–Yau morphisms automatically inherits an \((n + 1)\)-Calabi–Yau structure.

## 2.2 Existence and uniqueness of cyclic lifts

**Proposition 2.3** ([29], Section 5). Suppose \(B\) is a smooth dg-category. If \(B\) is almost \(n\)-Calabi–Yau, then \(HH_i(B) \simeq HH_{n-i}(B)\) for every \(i \in \mathbb{Z}\). Furthermore, if \(B\) is concentrated in degree zero then

\(\text{(a) } HH_i(B) = 0 \text{ for all } i \neq 0, 1, \ldots, n;\)

\(\text{(b) } HC^-_i(B) = 0 \text{ for all } i > n;\)

\(\text{(c) the natural map } HC^-_n(B) \rightarrow HH_n(B) \text{ is an isomorphism.}\)

In particular, every almost \(n\)-Calabi–Yau structure on \(B\) admits an \(n\)-Calabi–Yau lift.

**Proof.** This is essentially [29, Proposition 5.5, Corollary 5.6 & Proposition 5.7]. We reproduce the proof here for the reader's convenience.

We have an isomorphism of \(B\)-modules \(c^\vee : B^\vee[n] \simeq B\). It yields

\[
HH_{n-i}(B) \simeq \text{Hom}_{\text{Ho}(\text{Mod}_{B^+})}(B^\vee[n], B^i) \simeq \text{Hom}_{\text{Ho}(\text{Mod}_{B^+})}(B, B^i) \simeq HH_i(B).
\]

If \(B\) is concentrated in degree zero then its Hochschild homology and cohomology are concentrated in non-negative degrees, and thus, using the above identifications, \(HH_i(B) = 0\) for all \(i \neq 0, 1, \ldots, n\). We then consider the negative cyclic complex, which is given by taking formal power series in a degree 2 variable \(u\) with coefficients in the Hochschild complex, and
differential being given as $d - u\delta$, where $\delta$ is the mixed differential. The first page of the spectral sequence associated with the filtration by powers of $u$ reads as follows:

\[
\begin{array}{cccccc}
0 & u\mathrm{HH}_0(\mathcal{B}) & u\delta & u^2\mathrm{HH}_1(\mathcal{B}) & u\delta & \cdots & u^{n+1}\mathrm{HH}_n(\mathcal{B}) \\
\mathrm{HH}_0(\mathcal{B}) & u\delta & u\mathrm{HH}_1(\mathcal{B}) & u\delta & \cdots & u^n\mathrm{HH}_n(\mathcal{B}) & 0 \\
\mathrm{HH}_1(\mathcal{B}) & u\delta & u\mathrm{HH}_2(\mathcal{B}) & u\delta & \cdots & 0 & \\
\cdots & & & & & & \\
\mathrm{HH}_n(\mathcal{B}) & 0 & 0 & \cdots & \\
\end{array}
\]

This proves (a) and (b). \qed

**Remark 2.4.** Under the assumption of Proposition 2.3, the duality isomorphism extends to Hochschild homology with values in any $\mathcal{B}$-bimodule $\mathcal{M}$: $\mathrm{H}^i(\mathcal{B}, \mathcal{M}) \cong \mathrm{H}_{n-i}(\mathcal{B}, \mathcal{M})$. Moreover, if both $\mathcal{B}$ and $\mathcal{M}$ are concentrated in degree 0, then (a) still holds: $\mathrm{H}_i(\mathcal{B}, \mathcal{M})$ vanishes for all $i \neq 0, \ldots, n$.

**Theorem 2.5.** Let $F : \mathcal{B} \to \mathcal{C}$ be a functor between smooth dg-categories that are concentrated in degree zero. Every almost $n$-Calabi–Yau structure on $F$ admits a unique $n$-Calabi–Yau lift.

**Proof.** First of all, we know from Proposition 2.3 that the almost $n$-Calabi–Yau structure $c_B \in \mathrm{HH}_n(\mathcal{B})$ on $\mathcal{B}$ uniquely lifts to an $n$-Calabi–Yau structure $c_B^- \in \mathrm{HC}_n^-(\mathcal{B})$. The other part of the almost $n$-Calabi–Yau structure on $F$ is a homotopy from $F(c_B)$ to 0, which amounts to the choice of a relative lift $c_F \in \mathrm{HH}_{n+1}(\mathcal{C}, \mathcal{B})$ of $c_B$. Indeed, $\mathrm{HH}_i(\mathcal{C}, \mathcal{B})$ is defined as the $(−i)$-th cohomology of the homotopy cofiber (or, mapping cone) of $\mathrm{HH}(\mathcal{B}) \to \mathrm{HH}(\mathcal{C})$, so that we have a long exact sequence

\[
\cdots \to \mathrm{HH}_{n+1}(\mathcal{C}, \mathcal{B}) \to \mathrm{HH}_n(\mathcal{B}) \to \mathrm{HH}_n(\mathcal{C}) \to \mathrm{HH}_n(\mathcal{C}, \mathcal{B}) \to \cdots
\]

The non-degeneracy of $c_F$ tells us that the nul-homotopic sequence of $\mathcal{C}^e$-modules

\[
\mathcal{C}^e[n] \to \mathcal{B}^e[n] \otimes_{\mathcal{B}^e} \mathcal{C}^e \simeq \mathcal{B} \otimes_{\mathcal{B}^e} \mathcal{C}^e \to \mathcal{C}
\]

is actually a homotopy fiber sequence. Applying $\mathrm{Hom}_{\mathrm{Ho}(\mathcal{Mod}_{\mathcal{C}^e})}(−, \mathcal{C})$ yields a long exact sequence

\[
\cdots \to \mathrm{HH}^k(\mathcal{C}) \to \mathrm{H}^k(\mathcal{B}, \mathcal{C}) \simeq \mathrm{H}_{n-k}(\mathcal{B}, \mathcal{C}) \to \mathrm{HH}_{n-k}(\mathcal{C}) \to \mathrm{HH}^{k+1}(\mathcal{C}) \to \cdots
\]

Hence, using that Hochschild homology and cohomology of $\mathcal{C}$ vanishes for negative indices (because $\mathcal{C}$ is concentrated in degree 0), together with the version from Remark 2.4 of the vanishing property (a), we get that the Hochschild homology (and cohomology) of $\mathcal{C}$ vanishes in degrees $i \neq 0, \ldots, n + 1$. We again look at the first page of the Hochschild-to-negative cyclic spectral sequence:
0 \xrightarrow{u\delta} u^2HH_1(\mathcal{C}) \xrightarrow{u\delta} \cdots \xrightarrow{u\delta} u^{n+2}HH_{n+1}(\mathcal{C})

\begin{align*}
HH_0(\mathcal{C}) & \xrightarrow{u\delta} uHH_1(\mathcal{C}) \xrightarrow{u\delta} \cdots \xrightarrow{u\delta} u^{n+1}HH_{n+1}(\mathcal{C}) \xrightarrow{0} \\
HH_1(\mathcal{C}) & \xrightarrow{u\delta} uHH_2(\mathcal{C}) \xrightarrow{u\delta} \cdots \\
& \vdots \\
HH_n(\mathcal{C}) & \xrightarrow{u\delta} uHH_{n+1}(\mathcal{C}) \xrightarrow{0} 0 \\
HH_{n+1}(\mathcal{C}) & 0 0
\end{align*}

Putting this together, we obtain the following morphism of exact sequences:

\begin{align*}
0 \longrightarrow HC_{n+1}^{-}(\mathcal{C}) & \longrightarrow HC_{n+1}^{-}(\mathcal{C},\mathcal{B}) \longrightarrow HC_{n}^{-}(\mathcal{B}) \longrightarrow HC_{n}^{-}(\mathcal{C}) \\
\sim & \quad \sim \\
0 \longrightarrow HH_{n+1}(\mathcal{C}) & \longrightarrow HH_{n+1}(\mathcal{C},\mathcal{B}) \longrightarrow HH_{n}(\mathcal{B}) \longrightarrow HH_{n}(\mathcal{C})
\end{align*}

The injectivity of the rightmost arrow follows from the fact that

\[ HC_{n}^{-}(\mathcal{C}) \simeq \ker (HH_{n}(\mathcal{C}) \to uHH_{n+1}(\mathcal{C})) , \]

and it implies that the image of \( c_{\mathcal{B}} \) via \( HC_{n}^{-}(\mathcal{B}) \to HC_{n}^{-}(\mathcal{C}) \) vanishes (because the image of \( c_{\mathcal{B}} \) through \( HH_n(\mathcal{B}) \to HH_n(\mathcal{C}) \) does so). Therefore \( c_{\mathcal{B}} \) lifts to a relative class in \( HC_{n+1}^{-}(\mathcal{C},\mathcal{B}) \). The map from the affine space of relative lifts of \( c_{\mathcal{B}} \) to the affine space of relative lifts of \( c_{\mathcal{B}} \) is affine and modelled on the linear map \( HC_{n+1}^{-}(\mathcal{C}) \to HH_{n+1}(\mathcal{C}) \), which is an isomorphism.

Using that both affine spaces are non-empty, we get that the map from relative lifts of \( c_{\mathcal{B}} \) to relative lifts of \( c_{\mathcal{B}} \) is a bijection. Therefore we get that a cyclic lift of \( c_{\mathcal{F}} \) exists and is unique. 

3 Calabi–Yau structures associated with \( k[x^{\pm 1}] \)

3.1 A Calabi–Yau structure on \( k[x^{\pm 1}] \)

Let \( A = k[x^{\pm 1}] = k[\mathbb{G}_m] \). It is the function ring of a smooth affine algebraic variety; hence 1-Calabi–Yau structures on \( A \) are exactly non-vanishing top degree (here, degree 1) forms. The Calabi–Yau structure we consider on \( A \) is, up to a scalar, \( \alpha := d_{\mathcal{R}} \log(x) = x^{-1}d_{\mathcal{R}}x \).

In the rest of this subsection, we provide descriptions of this 1-Calabi–Yau structure that will be convenient for later purposes.

**Remark 3.1.** Notice that the inverse morphism \( \text{inv} : x \mapsto x^{-1} \) allows to identify \((A, \alpha)\) with \((A, -\alpha)\). We also observe that \( \alpha \) is invariant under rescaling maps \( x \mapsto qx, q \in k^\times \) (i.e. it is of zero weight for the action of \( \mathbb{G}_m \) on itself by multiplication).
Remark 3.2. In [37], Yeung also considers a Calabi–Yau structure on \( k[z^\pm 1] \), which is different form ours: Yeung’s Calabi–Yau structure is given by \( d_{dR} z \), and is exact, as opposed to ours. On moduli of representations, the Calabi–Yau structure we consider gives back the 1-shifted symplectic structure that encodes the quasi-hamiltonian formalism (see Section 5 below); we expect that Yeung’s Calabi–Yau structure rather leads to a linearized version of it. As a matter of fact, if one considers the \( I \)-adic completion \( \hat{A} \) at the kernel \( I \) of the evaluation at \( x = 1 \), the morphism \( k[z] \to \hat{A} \) sending \( z \) to log(\( x \)) is well-defined and sends the canonical Calabi–Yau structure \( d_{dR} z \) on \( k[z] \) to \( \alpha \).

3.1.1 The cyclic cycle

We work with the normalized Hochschild complex \( C_n(A) = A \otimes \tilde{A}^\otimes n \) where \( \tilde{A} = A/k \), with Hochschild differential \( b \). On \( C_n(A) \), the Connes boundary map is given by

\[
B(x_0 \otimes \cdots \otimes x_n) = \sum_{i=0}^{n} (-1)^{ni} x_i \otimes \cdots \otimes x_n \otimes x_0 \otimes \cdots \otimes x_{i-1}.
\]

We set

\[
2\alpha_n = (x^{-1} \otimes x)^\otimes n - (x \otimes x^{-1})^\otimes n \in C_{2n-1}(A),
\]

so that

\[
b(\alpha_n) = 2(1 \otimes \alpha_{n-1}) \quad \text{and} \quad B(\alpha_n) = 2n(1 \otimes \alpha_n).
\]

A direct computation then shows that

\[
\alpha = \sum_{k \geq 0} k! u^k \alpha_{k+1}
\]

satisfies \( (b - uB)(\alpha) = 0 \).

3.1.2 Proof of non-degeneracy

We want to prove that \( \alpha_1 = \frac{1}{2}(x^{-1} \otimes x - x \otimes x^{-1}) \) is non-degenerate. First observe that the class of \( x^{-1} \otimes x \) equals the one of \( -x \otimes x^{-1} \) (and thus, the one of \( \alpha_1 \)) in \( HH_1(A) \simeq \Omega^1_A \). Indeed, in (cohomological) degree \(-1\) the Hochschild homology of \( A \) is \( \Omega^1_A = k[x^\pm 1]d_{dR}x \).

The class of \( x^{-1} \otimes x \), resp. \( -x \otimes x^{-1} \), is computed via the Hochschild–Kostant–Rosenberg (HKR) map \( a \otimes b \mapsto \text{ad}_{dR}b \), and we find

\[
x^{-1}d_{dR}x, \quad \text{resp.} \quad -xd_{dR}(x^{-1}) = x^{-2}d_{dR}x = x^{-1}d_{dR}x.
\]

Hence it is sufficient to prove that the Hochschild 1-cycle \( x^{-1} \otimes x \) is non-degenerate.

The reduced Bar resolution of \( A \) is given by

\[
\hat{B}(A) = \bigoplus_{n \geq 0} (A \otimes \tilde{A}^\otimes n \otimes A)[n]
\]

with the usual differential being given by an alternating sum of products of successive elements. We also have a smaller resolution

\[
R(A) = A^e[1] \oplus A^e
\]

with differential sending \( 1 \otimes 1 \) to \( x \otimes 1 - 1 \otimes x \). Its dual is

\[
R(A)^\vee = A^e \oplus A^e[-1]
\]
with the same formula for the differential.

There’s a map \( R(A) \to \tilde{B}(A) \). In degree 0 it is the identity, and in degree \(-1\) it is given by \( f \otimes g \mapsto f \otimes x \otimes g \). Using this smaller resolution we obtain the “small Hochschild complex”:

\[
A[1] \oplus A
\]

with zero differential. It maps inside the standard Hochschild complex as follows: in degree 0 it is the identity, and in degree \(-1\) it sends \( f \) to \( f \otimes x \). (this map is in fact a quasi-inverse to the HKR quasi-isomorphism). In the small Hochschild complex, the class of interest reads as \( x^{-1} \), and one can show that as a map

\[
R(A)[1] \longrightarrow R(A)
\]

it is nothing but the product with \( x^{-1} \otimes 1 \) (in both degrees), which is an isomorphism of complexes.

**Remark 3.4.** We could have proven non-degeneracy first, and then use \([29, \text{ Proposition 5.7}]\) (see also Proposition 2.3 above) in order to obtain the existence (and uniqueness) of a cyclic lift.

### 3.1.3 Yet another description of the Calabi–Yau structure on \( k[x^{\pm 1}] \)

For every \( n \)-Calabi–Yau category \( A \), with Calabi–Yau structure \( c \), one can consider the same category with opposite Calabi–Yau structure \( -c \), and denote it \( \tilde{A} \). Then the functor \( A \coprod \tilde{A} \to A \) is relative Calabi–Yau.

Let \( k = ke \) be the terminal dg-category (\( e \) denotes the identity of the single object); it is obviously 0-Calabi–Yau, with Calabi–Yau structure being \( e \).

**Proposition 3.5.** There is an equivalence

\[
k[x^{\pm 1}] \simeq k \coprod_{k[1]} k
\]

of 1-Calabi–Yau dg-categories, where the Calabi–Yau structure on the left-hand-side is \( \alpha \), and the one on the right-hand-side is obtained as a Calabi–Yau push-out.

**Proof.** First of all we introduce the interval dg-category \( kI \): it is the \( k \)-linearization of the category \( I = 1 \leftrightarrow 2 \) with two objects and an isomorphism \( x \) between them. Observe that we have a factorization \( k \coprod_{k[1]} k \to kI \to k \), where the first functor is a cofibration (the inclusion into \( kI \) of its subcategory of objects), and the second functor is a trivial fibration. Hence our homotopy push-out can be computed as the strict push-out \( k \coprod_{k[1]} kI \simeq k[x^{\pm 1}] \). We thus get the requested equivalence of dg-categories. It remains to prove that the 1-Calabi–Yau structures coincide. Thanks to Proposition 2.3, it is sufficient to prove that the underlying Hochschild classes coincide.

Finally, the 0-cycle \( e_1 - e_2 \) is homotopic to zero in the cofibrant replacement \( kI \) of \( k \): \( e_1 - e_2 = b(\alpha_1) \), where \( \alpha_1 \) still makes sense for \( kI \).

### 3.2 Relative Calabi–Yau structures on evaluations \( k[x^{\pm 1}] \to k \)

The pull-back of the closed 1-form \( \alpha = d_{dR} \log(x) \) along any \( k \)-point

\[
q : A = k[x^{\pm 1}] \longrightarrow k
\]
of $G_m$ (i.e. $q \in k^\times$) obviously vanishes. This tells us that the morphism $q$ is relative pre-Calabi–Yau in the sense of [6].

**Lemma 3.6.** The above relative pre-Calabi–Yau structure is non-degenerate.

**Proof.** One first observes that both $(R(A)^\vee[1]) \otimes A^e$ and $R(A) \otimes A^e$ are isomorphic to $k[1] \oplus k$ with zero differential. Moreover, after applying $\otimes k^e$, the isomorphism (3.3) becomes the multiplication by $q^{-1}$ on each component. Then recall that $k^\vee = k$, so that the morphism

$$k^\vee[1] = k[1] \to k[1] \oplus k = (R(A)^\vee[1]) \otimes A^e,$$

is the obvious inclusion, resp. projection. Hence the map

$$k^\vee[1] \to \text{fib } \left( R(A) \otimes A^e \to k \right)$$

identifies with the map

$$k[1] \xrightarrow{q^{-1}} k[1] \simeq \text{fib}(k[1] \oplus k \to k).$$

This proves the non-degeneracy.

**3.3 A Calabi–Yau cospan**

Our aim is to prove that the cospan

$$k[x^{\pm 1}] \coprod k[y^{\pm 1}] \to k[x^{\pm 1}, y^{\pm 1}] \leftarrow k[z^{\pm 1}], \quad (3.7)$$

where the rightmost map is $z \mapsto xy$, is relative Calabi–Yau in the sense of [6].

Set $\beta_1 = \frac{1}{2}(y^{-1} \otimes x^{-1} \otimes xy - y \otimes y^{-1}x^{-1} \otimes x)$, which satisfies

$$\alpha_1(xy) - (\alpha_1(x) + \alpha_1(y)) = b(\beta_1).$$

**Lemma 3.8.** The above homotopy $\beta_1$ is non-degenerate, and thus defines an almost 1-Calabi–Yau structure on the cospan $(3.7)$. This almost 1-Calabi–Yau structure lifts uniquely to a 1-Calabi–Yau structure.

**Proof.** As a preliminary observation, let us recall on the one hand that $B := k(x^{\pm 1}, y^{\pm 1})$ also has a small resolution as a $B$-bimodule:

$$R(B) = (B^e)^{\otimes 2}[1] \oplus B^e$$

with differential sending $(1 \otimes 0, 0)$ to $x \otimes 1 - 1 \otimes x$, and $(0, 1 \otimes 1)$ to $y \otimes 1 - 1 \otimes y$. Therefore

$$R(B)^\vee = B^e \oplus (B^e)^{\otimes 2}[-1]$$

with differential sending $1 \otimes 1$ to $(x \otimes 1 - 1 \otimes x, y \otimes 1 - 1 \otimes y)$.

As the maps $\alpha_1(xy)$ and $\alpha_1(x) + \alpha_1(y)$ are homotopic via $\beta_1$, the following diagram is homotopy commutative

$$\begin{CD}
B^\vee[1] \quad @>>> \quad A^\vee \otimes B^e[1] \simeq A \otimes A^e \otimes B^e \\
(A^{\otimes 2})^\vee \otimes B^e[1] \quad @>>> \quad A^{\otimes 2} \otimes B^e \quad @>>> \quad B
\end{CD}$$

\[\text{We warn again the reader that pre-Calabi–Yau in the sense of [6] (see also [32]) is the non-commutative analog of pre-symplectic, and differs from the pre-Calabi–Yau notion from [16] that is the non-commutative analog of a Poisson structure.}\]
where $\mathcal{A} = k[x^{\pm 1}]$. Following §3.1.2, $\mathcal{A} \otimes \mathcal{B} \simeq \mathcal{B}[1] \oplus \mathcal{B}$, with differential sending $1 \otimes 1$ to $x \otimes 1 - 1 \otimes x$. Hence, we get that the fibre of the map
\[(\mathcal{B}[1])^\oplus \oplus (\mathcal{B})^\oplus \to (\mathcal{B})^\oplus \oplus[1] \oplus \mathcal{B}
\]
induced by $\alpha_1(xy) - \alpha_1(x) + \alpha_1(y)$ is isomorphic to $R(\mathcal{B})^\vee[1] = \mathcal{B}[1] \oplus (\mathcal{B})^\oplus[2]$. Then, using Theorem 2.5, we get that $\beta_1$ lifts to a unique homotopy $\beta$ between $\alpha(xy)$ and $\alpha(x) + \alpha(y)$. Therefore the cospan (3.7) carries a 1-Calabi–Yau structure. Below we give an alternative presentation of this cospan.

### 3.3.1 Another description of the Calabi–Yau cospan

Observe that we have the following (strict) commuting diagram in the category $\text{(Cat}_{k}^\text{sm})_{k/HC}^-$ of smooth dg-categories equipped with a negative cyclic 0-cycle (in order to lighten the notation, we omit coproducts):

\[
\begin{array}{ccc}
\emptyset & \xrightarrow{k} & k \\
\downarrow & & \downarrow \\
k & \xrightarrow{k} & k \\
\downarrow & & \downarrow \\
k & \xrightarrow{k} & k \\
\downarrow & & \downarrow \\
k & \xrightarrow{k} & k \\
\end{array}
\]

It admits a replacement by a (homotopy coherent) commuting diagram in the $\infty$-category $\text{(Cat}_{k}^\text{sm})_{k/HC}^{-}$:

\[
\begin{array}{ccc}
kI & \xrightarrow{kI} & kI \\
\downarrow & & \downarrow \\
kI & \xrightarrow{kI} & kI \\
\downarrow & & \downarrow \\
kI & \xrightarrow{kI} & kI \\
\downarrow & & \downarrow \\
kI & \xrightarrow{kI} & kI \\
\end{array}
\]

Observe that the above diagram strictly commutes in $\text{Cat}_{k}$, but that the negative cyclic 0-cycles only match up to homotopy.

By composing horizontal cospans we obtain a new (homotopy) commuting diagram in the $\infty$-category $\text{(Cat}_{k}^\text{sm})_{k/HC}^{-}$:

\[
\begin{array}{ccc}
k[z^{\pm 1}] & \xrightarrow{k} & k[z^{\pm 1}] \\
\downarrow & & \downarrow \\
k[x^{\pm 1}, y^{\pm 1}] & \xrightarrow{k} & k[x^{\pm 1}, y^{\pm 1}] \\
\downarrow & & \downarrow \\
k[x^{\pm 1}] \coprod k[y^{\pm 1}] & \xrightarrow{k} & k[x^{\pm 1}] \coprod k[y^{\pm 1}] \\
\end{array}
\]
One can finally see that the vertical cospan of dg-categories coincides with \( (3.7) \). Additionally, we have 1-cycles \( c_k \) and \( c_{x,y} \) in \( \text{HC}^-(k[z^\pm 1]) \) and \( \text{HC}^-(k[x^\pm 1][k/y^\pm 1]) \), respectively, together with a homotopy \( c_{x,y,z} \) between their images in \( \text{HC}^-(k(x^\pm 1, y^\pm 1)) \).

**Proposition 3.9.** The triple \( (c_{x,y}, c_z, c_{x,y,z}) \) defines a 1-Calabi–Yau structure on \( (3.7) \), that coincides with the one from Lemma 3.8.

**Proof.** As we have already seen in Proposition 3.5, the 1-Calabi–Yau structures on \( k[x^\pm 1][k/y^\pm 1] \) match up: \( c_{x,y} \sim \alpha(x) + \alpha(y) \).

They also match on \( k[z^\pm 1] \), but there is a subtlety that is worth noticing. As usual, according to the uniqueness of cyclic lifts from Proposition 2.3, in order to prove that \( c_z \sim \alpha(z) \) it is sufficient to prove that \( c_z^2 \sim \alpha(z)^2 = \alpha_1(z) \). Now, computed strictly, the top horizontal push-out gives the \( k \)-linearization \( \mathcal{C} \) of a category with two objects 1, 2 and two isomorphisms \( x : 1 \to 2 \) and \( y : 2 \to 1 \). Of course, we have an equivalence \( k[z^\pm 1] \to \mathcal{C} \), sending \( z \) to \( xy \). Following a similar calculation as in the proof of Proposition 3.5, we get on \( \mathcal{C} \) the Hochschild 1-cycle \( \alpha_1(x) + \alpha_1(y) \). Up to a Hochschild boundary, this matches up with the image of \( \alpha_1(z) \) through the equivalence given by \( z \mapsto xy \). Indeed, the formula for the homotopy \( \beta_1 \) still makes sense in \( \mathcal{C} \).

It remains to prove that the homotopy \( c_{x,y,z} \) matches with \( \beta \). As the underlying Hochschild homotopy \( \beta_1 = \beta^2 \) is non-degenerate (thanks to Lemma 3.8), according to the uniqueness of cyclic lifts from Theorem 2.5, it suffices to prove that the underlying Hochschild homotopies \( c_z^2 \) and \( \beta \) coincide. We already proved it, as \( \beta_1 \) is the homotopy that identifies \( \alpha_1(x) + \alpha_1(y) \) with \( \alpha_1(z) \) in \( \mathcal{C} \).

**Remark 3.10.** Let us put what we have done so far in a more general perspective, by first recalling from [7, §5.1] that for a closed oriented \( d \)-manifold \( M \), the \( k \)-linearization \( \mathcal{L}(M) := \text{dg}(\text{Sing}(M)) \) of the fundamental \( \infty \)-groupoid of \( M \) carries a \( d \)-Calabi–Yau structure. Moreover, in loc. cit. the authors also prove that if \( N \) is a compact oriented \( (d+1) \)-manifold with boundary \( \partial N = M \), then one gets a \( d \)-Calabi–Yau structure on the natural functor \( \mathcal{L}(M) \to \mathcal{L}(N) \). We conjecture the existence of a symmetric monoidal \( (\infty,n) \)-category \( \text{CY}_n \) of \( n \)-iterated \( s \)-Calabi–Yau cospan structures, similar to the iterated category of lagrangian correspondences sketched in [9], and rigorously constructed in [11]. We also conjecture that the functor \( \text{dg}(\text{Sing}(-)) \) leads to a fully extended oriented TFT in every dimension: i.e. it should admit an upgrade to a symmetric monoidal \( (\infty,n) \)-functor

\[
\text{Bord}^\text{op}_{n} \longrightarrow \text{CY}_n^0
\]

for every \( n \) (in particular, \( k \) is \( n \)-dualizable in \( \text{CY}_n^0 \)). For the above presentation of the Calabi–Yau cospan structure on \( k[x^\pm 1, y^\pm 1] \), we took inspiration from a construction of the pair-of-pants as a suitable composition of 2-iterated oriented bordisms (see subsection 5.2 below, where this decomposition of the pair-of-pants is made explicit), and guessed the diagram one shall write by pretending that the conjecture was known.

**Remark 3.11.** The Calabi–Yau push-out of this cospan with the evaluation Calabi–Yau morphism \( q : k[z^\pm 1] \to k \) from §3.2 gives the Calabi–Yau cospan associated with the Calabi–Yau isomorphism \( k[x^\pm 1] \to k[y^\pm 1] \) given by \( x \mapsto q^{-1}y \) (see Remark 3.1). More precisely, the push-out gives a morphism

\[
k[x^\pm 1][k[y^\pm 1] \to k[x^\pm 1, y^\pm 1]/(xy = q),
\]

under which the image of \( \alpha_1(x) + \alpha_1(y) \) is identically 0. Then using that \( \text{inv} \) gives an isomorphism between the Calabi–Yau structure and its inverse on \( k[x^\pm 1] \) (see Remark 3.1, again), we obtain the desired Calabi–Yau cospan from \( k[x^\pm 1] \) to \( k[y^\pm 1] \).
4 Multiplicative preprojective algebras

Consider a quiver $Q$, which consists in a vertex set $V$, and an oriented edge set $E$: to each edge $e$ we associate a source $s(e)$ and a target $t(e)$ in $V$. We consider its double version $\overline{Q} = (V, \overline{E} = E \cup E^*)$, where $E^*$ consists in reverse arrows $e^* : t(e) \to s(e)$, and extend $*$ in an involution of $\overline{E}$ by setting $e^{**} = e$ for every $e \in E$. We also set $\epsilon(e) = 1$ and $\epsilon(e^*) = -1$ for all $e \in E$. As mentioned in the introduction, Crawley-Boevey and Shaw introduced in [13] the multiplicative preprojective algebra $\Lambda^q(Q)$, where $q \in (k^*)^V$. It is given as the quotient of a localization of $k\overline{Q}$ by the relation

$$\prod_{e \in \overline{E}} (1 + ee^*) \epsilon(e) - \sum_{v \in V} q_v e_v$$

where $e_v$ denotes the length 0 idempotent path at $v$. It is thus required to invert all $1 + ee^*$ for $e \in E^*$, which actually amounts to inverting $1 + ee^*$ for all $e \in \overline{E}$. We denote $k\overline{Q}_{loc}$ the localization of $k\overline{Q}$ with respect to these elements.

The definition of $\Lambda^q(Q)$ a priori requires an ordering on $\overline{E}$, but the resulting quotient actually doesn’t depend on it (up to isomorphism [13, Theorem 1.4]).

Remark 4.1. We can either view $\Lambda^q(Q)$ as an algebra, or as a category (with objects the vertices of $Q$, that correspond to the idempotents of $\Lambda^q(Q)$). There is a Morita morphism from one to another, so that it doesn’t matter for what we do (see [6, Remark 5.4]).

4.1 Relative Calabi–Yau structure for the $A_2$ quiver

Consider the quiver $A_2 = (V = \{1, 2\}, E = \{e : 1 \to 2\})$, with orthogonal idempotents $e_1$ and $e_2$ satisfying $1 = e_1 + e_2$, and write

$$a_1 = e_1 + e^* e \text{ and } a_2 = e_2 + ee^*.$$ 

Note that

$$1 + e^* e \text{ invertible } \iff a_1 \text{ invertible } \iff a_2 \text{ invertible } \iff 1 + ee^* \text{ invertible},$$

in which case

$$\begin{align*}
(1 + e^* e)^{-1} &= a_2 + a_1^{-1} \\
 a_2^{-1} &= e_2 - ea_1^{-1} e^* \\
 a_1^{-1} &= e_1 - e a_2^{-1} e
\end{align*} \quad (4.2)$$

Thus in the $A_2$ case, the product in the multiplicative preprojective relation reads

$$(1 + ee^*)(1 + e^* e)^{-1} = a_2 + a_1^{-1} = (1 + e^* e)^{-1}(1 + ee^*).$$

Denote by $\mathcal{B}$ the localization $k\overline{A_2[a_1^{-1}, a_2^{-1}]}$, and define morphisms $\mu_i : k[x_i^{\pm 1}] \to \mathcal{B}$, $i \in \{1, 2\}$, by setting

$$\mu_1(x_1) = a_1^{-1} \quad \text{and} \quad \mu_2(x_2) = a_2.$$ 

Equalities (4.2) further imply

$$\begin{align*}
a_2^{-1} e &= ea_1^{-1} \\
e^* a_2^{-1} &= a_1^{-1} e^* \\
e^* ea_1^{-1} &= e_1 - a_1^{-1} \\
 ee^* a_2^{-1} &= e_2 - a_2^{-1}
\end{align*} \quad (4.3)$$

14
4.1.1 The homotopy

Note that $\mu_1$ maps $\alpha_1$ to $\frac{1}{2}(a_1 \otimes a_1^{-1} - a_1^{-1} \otimes a_1)$, and $\mu_2$ maps $\frac{1}{2}(\alpha_1 \otimes a_2^{-1} \otimes a_2 - a_2 \otimes a_2^{-1})$ where tensor products are performed over the algebra $R = \oplus_{e \in V} ke_v$. Thus

$$2(\mu_1(\alpha_1) + \mu_2(\alpha_2)) = e^* e \otimes a_1^{-1} - a_1^{-1} \otimes e^* e + a_2^{-1} \otimes ee^* - ee^* \otimes a_2^{-1}$$
$$+ e_1 \otimes a_1^{-1} - a_1^{-1} \otimes e_1 + a_2^{-1} \otimes e_2 - e_2 \otimes a_2^{-1}$$
$$= e^* e \otimes a_1^{-1} - a_1^{-1} \otimes e^* e + a_2^{-1} \otimes ee^* - ee^* \otimes a_2^{-1}$$
$$+ 1 \otimes (a_1^{-1} - a_2^{-1})$$

as $a_i^{-1} \otimes e_i = a_i^{-1} \otimes 1 = 0$ in the normalized Hochschild complex. Direct computations, helped by (4.3), show that

$$e^* e \otimes a_1^{-1} - a_1^{-1} \otimes e^* e + a_2^{-1} \otimes ee^* - ee^* \otimes a_2^{-1}$$

is the image under $b$ of

$$e^* \otimes e \otimes a_1^{-1} + a_1^{-1} \otimes e^* e - e^* \otimes a_2^{-1} \otimes e - a_2^{-1} \otimes e \otimes e^*.$$

Also,

$$1 \otimes (a_1^{-1} - a_2^{-1}) = 1 \otimes (a_1^{-1} - e_1 - a_2^{-1} + e_2) \quad \text{[normalization]}$$
$$= 1 \otimes (ee^* a_2^{-1} - e^* ea_1^{-1}) \quad \text{[(4.3)]}$$
$$= -B(e^* \otimes ea_1^{-1}) \quad \text{[(4.3)]}$$
$$= bB(e^* \otimes ea_1^{-1}).$$

Hence $\mu_1(\alpha_1) + \mu_2(\alpha_2)$ is the image under $b$ of

$$\beta_1 = \frac{1}{2} (e^* \otimes e \otimes a_1^{-1} + a_1^{-1} \otimes e^* e - e^* \otimes a_2^{-1} \otimes e - a_2^{-1} \otimes e \otimes e^* + B(e^* \otimes ea_1^{-1}))$$
$$= \frac{1}{2} (e^* \otimes e \otimes \mu + \mu \otimes e^* e - e^* \otimes \mu^{-1} \otimes e - \mu^{-1} \otimes e \otimes e^*$$
$$+ 1 \otimes e^* \otimes e \mu - 1 \otimes \mu^{-1} e \otimes e^*)$$

if $\mu = \mu_1(x_1) + \mu_2(x_2)$.

4.1.2 Non-degeneracy

**Proposition 4.5.** The cospan $\mu_1 \Pi - \mu_2$ carries an almost 1-Calabi–Yau structure, that lifts uniquely to a 1-Calabi–Yau structure thanks to Theorem 2.5.

**Proof.** Set $\mathcal{A} = k[x_1^\pm 1] \Pi k[x_2^\pm 1]$ and $u = \mu_1 \Pi - \mu_2$. Thanks to the existence of the homotopy $\beta_1$ given by (4.4), the following diagram homotopy commutes:

$$\begin{array}{ccc}
\mathcal{B}^*[1] & \xrightarrow{u^*[1]} & \mathcal{A}^*[1] \otimes \mathcal{B}^e \\
\uparrow \downarrow & & \uparrow \downarrow \\
\text{fib}(u) & \xrightarrow{\alpha_1 \otimes \mathcal{B}^e} & \mathcal{A} \otimes \mathcal{B}^e \xrightarrow{\mu} \mathcal{B}
\end{array}$$

To show the non-degeneracy, we need to prove that the vertical maps in (4.6) are isomorphisms. Since $\mathcal{A}$ is 1-Calabi–Yau, it is sufficient to prove that the leftmost vertical map is
an isomorphism. Set \( A_i = k[x_i^{\pm 1}] \), and \( B_i^e = A_i \otimes B^e \) induced by \( \mu_i \). Using the resolutions from §3.1.2, we can replace \( A \otimes B^e \) with the complex

\[
(B_i^e \oplus B_i^e)[1] \oplus (B_i^e \otimes B^e_i)
\]

with differential

\[
d : (p_1 \otimes q_1, p_2 \otimes q_2) \mapsto (p_1 a_{i1}^{-1} \otimes q_1 - p_1 \otimes a_{i1}^{-1} q_1, p_{2a_2} \otimes q_2 - p_2 \otimes a_{2q_2})
\]

where \( p_i, q_i \in B \). A \( B \)-bimodule resolution of \( B \) is given by

\[
\Omega^1(B) \xrightarrow{d} B^e.
\]

By [27, Theoren 10.6] (see also [6, Remark 5.4]), we can identify \( \Omega^1(B) \) with \( B \otimes kE \otimes B \) and \( d'(1 \otimes v \otimes 1) = v \otimes 1 - 1 \otimes v \), where \( R \) still denotes \( \oplus_{v \in V} kE_v \). Here for \( A_2 \) the edge set \( E \) is simply \( \{e\} \). Hence, \( u \) is given by the following commutative diagram

\[
\begin{array}{ccc}
B_i^e \oplus B_i^e & \xrightarrow{f} & B \otimes kE \otimes B \\
\downarrow{d} & & \downarrow{d'} \\
B_i^e \oplus B_i^e & \xrightarrow{\tau} & B \otimes B.
\end{array}
\]

where

\[
f(p_1 \otimes q_1, p_2 \otimes q_2) = f_1(p_1 \otimes q_1) - f_2(p_2 \otimes q_2)
\]

\[
\tau(p_1 \otimes q_1, p_2 \otimes q_2) = p_1 \otimes q_1 - p_2 \otimes q_2.
\]

Let us give a concrete description of \( f \). We have a \( k \)-linear map \( \iota : kE \rightarrow B \otimes kE \otimes B \) which sends a path \( p = \alpha_1 \cdots \alpha_n, \alpha_i \in E \), to

\[
\sum_{i=1}^{n} \alpha_1 \cdots \alpha_{i-1} \otimes \alpha_i \otimes \alpha_{i+1} \cdots \alpha_n.
\]

This map has a natural \( B^e \)-linear extension \( B \rightarrow B \otimes kE \otimes B \), still denoted by \( \iota \), satisfying

\[
\iota(bb') = b \iota(b') + \iota(b)b'. \quad (4.7)
\]

Then it can be checked that the maps \( f_1 : B_i^e \rightarrow B \otimes kE \otimes B \) are given as \( B^e \)-linear maps by

\[
f_1(1 \otimes 1) = \iota(a^{-1})
\]

\[
f_2(1 \otimes 1) = -\iota(a_2).
\]

We then identify \( \text{fib}(u) \) with \( (f, \tau) \).

The resolution of \( B^e \) as a \( B^e \)-module is given by

\[
d'' : B \otimes B \rightarrow B \otimes kE \otimes B, \quad 1 \otimes e_i \otimes 1 \mapsto \sum_{a \in E} (a \otimes a^* \otimes 1 - 1 \otimes a^* \otimes a).
\]

In the \( A_2 \) case, this just reads

\[
d''(1 \otimes 1) = e \otimes e^* \otimes 1 - 1 \otimes e^* \otimes e + e^* \otimes e \otimes 1 - 1 \otimes e \otimes e^*.
\]
The equivalence
\[ g = \alpha_1 \otimes B^e : (B_1^1 \oplus B_2^1)[1] \oplus (B_1^2 \oplus B_2^2) \rightarrow (B_1^1 \oplus B_2^1)[1] \oplus (B_1^2 \oplus B_2^2) \]
is induced by the image of \( \alpha_1 \) under \( \mu_1 \Pi - \mu_2 \), hence by the internal product \( m \) with
\[ (a_1 \otimes 1 - 1 \otimes a_1, a_2^{-1} \otimes 1 - 1 \otimes a_2^{-1}) \]
on both terms, thanks to \S3.1.2. The homotopy \( \beta_1 \) defined by (4.4) induces a zero homotopy \( h \) of the map
\[ B^e[1] \xrightarrow{\text{ugu}^e[1]} B. \]

With the chosen resolutions, this yields a map \( h : B \otimes \wedge \otimes B \rightarrow B \otimes \wedge \otimes B \) such that the triangles in the following diagram commute
\[
\begin{array}{c}
B \otimes B \xrightarrow{d^e} B \otimes B \xrightarrow{\tau^e} B \otimes B
\end{array}
\]
where \( \tau^e(1 \otimes 1) = (1 \otimes 1, -1 \otimes 1) \). Now,
\[
f \tau^e(1 \otimes 1) = f m(1 \otimes 1, -1 \otimes 1)
= f (a_1 \otimes 1 - 1 \otimes a_1, 1 \otimes a_2^{-1} - a_2^{-1} \otimes 1)
= a_1 \iota(a_1^{-1}) - \iota(a_1^{-1})a_1 + \iota(a_2)a_2^{-1} - a_2^{-1} \iota(a_2)
= -\iota(a_1)a_1^{-1} + a_1^{-1} \iota(a_1) + \iota(a_2)a_2^{-1} - a_2^{-1} \iota(a_2)
= -(e^* \otimes e \otimes 1 + 1 \otimes e^* \otimes e)a_1^{-1} + a_1^{-1}(e^* \otimes e \otimes 1 + 1 \otimes e^* \otimes e)
+ (e \otimes e^* \otimes 1 + 1 \otimes e \otimes e^*)a_2^{-1} - a_2^{-1}(e \otimes e^* \otimes 1 + 1 \otimes e \otimes e^*)
= h d^e(1 \otimes 1)
\]
if (using (4.3))
\[
h(1 \otimes e \otimes 1) = a_2^{-1} e \otimes 1 - 1 \otimes e a_1^{-1}
\]
\[
h(1 \otimes e^* \otimes 1) = 1 \otimes e^* a_2^{-1} - a_1^{-1} \otimes e^* 1.
\]
The homotopy \( h \) therefore induces an isomorphism \( B^e[1] \xrightarrow{\text{ugu}} \text{fib}(u) \) as wished (it is the leftmost vertical map in (4.6)). \( \square \)

4.2 Fusion

Following [34], we use a fusion procedure to go from the \( A_2 \) case to the case of an arbitrary quiver \( Q = (V, E) \). The following endows the “noncommutative group-valued” moment map for \( kQ_{\text{loc}} = kQ[(1 + ee^*)^{-1}]_{e \in E} \), that defines the multiplicative preprojective algebra, with a Calabi–Yau structure.

**Theorem 4.8.** There is a 1-Calabi–Yau structure on the morphism
\[
\mu : \prod_{v \in V} k[z_w^{\pm 1}] \rightarrow kQ_{\text{loc}}
\]
\[
z_w \mapsto \prod_{e \in E \setminus \mu^{-1}(v)} (1 + ee^*) \times \prod_{e \in E \setminus \mu^{-1}(v)} (1 + e^*e)^{-1}.
\]
Proof. Denote by $Q^{\text{sep}}$ the quiver with same edge set $E$ but vertex set $\overline{E} = \{v_e = s(e), v_{e^*} = t(e)\}$. It is the disjoint union of $|E|$ copies of $A_2$ that we aim to glue by “fusing” vertices. This will be done using composition of Calabi–Yau structures by means of push-outs. Thanks to §4.5, we have a 1-Calabi–Yau morphism

$$\coprod_{e \in E} (k[x_e^\pm] \amalg k[y_e^\pm]) \to k[Q^{\text{sep}}](1 + ee^*)^{-1}$$

(4.9)
given by $x_e \mapsto (e_s(e) + e^* e)^{-1}$ and $y_e \mapsto e_t(e) + ee^*$. For each vertex $v \in V$, fix a total ordering of all edges of $E$ with target $v$ and the same with $E^*$. Consider $e, f = e + 1 \in E$, both with target $v$. We have a 1-Calabi–Yau cospan 3.7 given by

$$k[y_e^\pm] \coprod k[y_f^\pm] \to k(y_e^\pm, y_f^\pm) \leftarrow k[z_{e,f}^\pm]$$

with $z_{e,f} \mapsto y_e y_f$. Similarly, if $e^*, f^* = e^* + 1 \in E^*$, both with target $v$, we have a 1-Calabi–Yau cospan given by

$$k[x_e^\pm] \coprod k[x_f^\pm] \to k(x_e^\pm, x_f^\pm) \leftarrow k[z_{e,f}^\pm]$$

with $z_{e,f} \mapsto x_e x_f$. Finally, if $e = \max E \cdot t^{-1}(v)$ and $f^* = \min E^* \cdot t^{-1}(v)$, we have a 1-Calabi–Yau cospan given by

$$k[y_e^\pm] \coprod k[y_{f^*}^\pm] \to k(y_e^\pm, y_{f^*}^\pm) \leftarrow k[z_{e,f}^\pm]$$

with $z_{e,f} \mapsto y_e y_{f^*}$. Proceeding to ordered compositions of cospans, we get a 1-Calabi–Yau cospan given by

$$C_v := k\left( \left\langle (y_e^\pm)_{e \in E \cap u^{-1}(v)}, (x_e^\pm)_{e \in E \cap s^{-1}(v)} \right\rangle \right)$$

where coproducts and variables are ordered. Now fix an ordering on $V$, composing the above yields a cospan

$$\coprod_{e \in E} (k[x_e^\pm] \amalg k[y_e^\pm]) \to \coprod_{v \in V} C_v \leftarrow \coprod_{v \in V} k[z_{e}^\pm]$$

that can be composed with (4.9) in order to get a 1-Calabi–Yau structure on $\mu$ as expected.

Remark 4.10. Note that this proof is independent of the choice of the function $\epsilon : \overline{Q} \to \{\pm 1\}$ defining the preprojective multiplicative algebra.

### 4.3 Reduction

Consider a family of 1-Calabi–Yau morphisms $q_v : k[z_v^\pm] \to k$, $v \in V$; that is a collection $q = (q_v)_{v \in V} \in (k^V)^V$. Thanks to Lemma 3.6 and Theorem 4.8, we have a 2-Calabi–Yau structure on the push-out of $\mu$ with $\coprod_{v \in V} q_v$. To compute this push-out, let us use for each $v$ the $k[z_v^\pm]$-cofibrant replacement of $k$ given by $k(z'_v, z_v^\pm)$ where $z'_v$ lies in degree $-1$, $z_v$ in degree $0$ and the differential is given by $z'_v \mapsto z_v - q_v$. We thus get the following.
Theorem 4.11. For every $q \in (k^\times)^V(Q)$, there is a 2-Calabi–Yau structure on the dg-algebra $\Upsilon^q(Q)$ defined as follows:

- As a graded algebra, $\Upsilon^q(Q)$ is freely generated over $k$ by the bimodule $(kQ)_{\text{loc}} \otimes \mathbb{R} \left( \bigoplus_{v \in V} k_{z'_v} \right)$;
- The differential sends $z'_v$ to
  \[
  \left( \prod_{e \in E^{u \to t}(v)} (1 + e^*e) \times \prod_{e \in E^{t \to u}(v)} (1 + ee^*)^{-1} \right) - q_v.
  \]

Remark 4.12. • The zeroth cohomology of $\Upsilon^q(Q)$ is the deformed preprojective algebra $\Lambda^q(Q)$.
• The dg-algebra $\Upsilon^q(Q)$ coincides with the one of [3, §5.C] (in the case of a nodal curve with rational components), as well as the one of [17, Definition 4.3].
• Theorem 4.11 generalizes [37, Theorem 5.52] from star-shaped quivers to arbitrary ones.

5 Comparison: moduli of objects

The moduli of objects $\text{Perf}$ was introduced by Toën-Vaquié in [33] as a functor

$$
\text{Perf} : \text{Cat}_{f.t.}^{k} \to \text{dSt}_{k}^{Art}
$$

from the ∞-category of finite type dg-categories to the ∞-category of derived Artin $k$-stacks. For a finite type dg-category $A$ and a commutative differential graded $k$-algebra $B$, $\text{Perf}_A(B) := \text{Map}_{\text{Cat}_k}(A, \text{Mod}_{B}^{\text{perf}})$ consists in perfect $B$-module valued $A$-modules. In [22], $n$-shifted symplectic structures for Artin stack, as well as $n$-shifted lagrangian morphisms and correspondences (see also [9]) have been introduced. Calabi–Yau structures on dg-categories and functors can be considered as non-commutative analogs of shifted symplectic and lagrangian structures in the following sense: by [8, Theorem 5.5] (see also [32]), the moduli stack of objects $\text{Perf}$ sends $n$-Calabi–Yau structures to $(2-n)$-shifted symplectic structures, and can be extended to a functor from $n$-Calabi–Yau cospans to $(2-n)$-shifted lagrangian correspondences.

Another way of producing new shifted symplectic and lagrangian structures from old ones was discovered in [22, Theorem 2.5]: it is shown that for an $n$-shifted symplectic Artin stack $X$, the mapping stack $\text{Map}(\cdot, X)$ in $\text{dSt}_{k}^{Art}$ sends (nice enough) $d$-oriented Artin stacks to $(n-d)$-shifted symplectic stacks. By [9, Theorem 4.8] the functor $\text{Map}(\cdot, X)$ sends (nice enough) $d$-oriented cospans to $(n-d)$-shifted lagrangian correspondences. Note that the Betti-stack functor, denoted by $(\cdot)_B$, maps $d$-oriented manifolds to (sufficiently nice) $d$-oriented derived stacks.

5.1 Moduli of objects of $k[x^{\pm 1}]$, derived loop stacks, and the adjoint quotient

On the one hand, the 1-Calabi–Yau structure on $k[x^{\pm 1}]$ as constructed in Section 3 induces a 1-shifted symplectic structure on the derived stack $\text{Perf}_{k[x^{\pm 1}]}$. On the other hand, $\text{Perf}_{k[x^{\pm 1}]}$ is equivalent to the derived loop stack $\mathcal{L}\text{Perf}_{k} := \text{Map}(BZ, \text{Perf}_{k})$. Knowing
that \( BZ \simeq S^1_B \) is 1-oriented, and that \( \text{Perf}_k \) is 2-shifted symplectic (because \( k \) is 0-Calabi–Yau), we obtain, thanks to [22, Theorem 2.5], a transgressed 1-shifted symplectic structure on \( \mathcal{L}\text{Perf}_k \).

**Proposition 5.1.** There is an equivalence

\[
\text{Perf}_k[x^\pm 1] \simeq \mathcal{L}\text{Perf}_k
\]

as 1-shifted symplectic derived stacks.

**Proof.** On the one hand, recall that for every \( n \)-shifted symplectic derived stack \( X \), the derived loop stack \( \mathcal{L}X \) is equivalent, as an \((n - 1)\)-shifted symplectic derived stack, to the derived lagrangian intersection

\[
X \times_{X \times \overline{X}} X,
\]

where \( \overline{X} \) denotes the same derived stack equipped with the opposite \( n \)-shifted symplectic structure. Indeed, the functor \( \text{Map}((-)_B, X) \) is an oriented topological field theory (see [9, Theorem 4.8]), and as such it sends the gluing of two oriented manifolds along a common boundary to the corresponding derived lagrangian intersection. The case of interest for us is the one of \( S^1 \), that is obtained by gluing two closed intervals along two points:

\[
S^1 \simeq \text{pt} \coprod \text{pt} \coprod \text{pt},
\]

where \( \text{pt} \) denotes the point with its opposite orientation.

On the other hand, using Proposition 3.5 and the fact that \( \text{Perf} \) sends compositions of Calabi–Yau cospans to compositions of lagrangian correspondences (and, in particular, Calabi–Yau pushouts to lagrangian intersections), see [8] and [6, §6.1.2], we obtain that

\[
\text{Perf}_k[x^\pm 1] \simeq \text{Perf}_k \coprod_{\text{Perf}_k \times \text{Perf}_k} \text{Perf}_k \simeq \mathcal{L}\text{Perf}_k
\]

as 1-shifted symplectic derived stacks. \(\square\)

Finally, by restricting ourselves to the open substack consisting of perfect modules of amplitude 0 and fixed dimension \( n \), we get back the transgressed 1-shifted symplectic structure on \( \mathcal{L}(BGL_n) \) (recall that the open embedding \( BGL_n \hookrightarrow \text{Perf}_k \) is a 2-shifted symplectomorphism). According to [25], this 1-shifted symplectic structure coincides with the explicit one given on the adjoint quotient \( [GL_n/GL_n] \simeq L(BGL_n) \) by the quasi-hamiltonian formalism (see [9, 25]).

**Remark 5.2.** The 1-Calabi–Yau evaluation morphism \( q : k[x^\pm 1] \to k, q \in k^\times \), induces a 1-shifted lagrangian morphism \( \text{Perf}_k \to \text{Perf}_k[x^\pm 1] \). We let the reader check that, when restricted on the open substacks of amplitude 0 modules of dimension \( n \), it gives back the lagrangian morphism \( BGL_n \to [GL_n/GL_n] \) corresponding to the group-valued moment map \( \text{pt} \to GL_n \) given by \( q\text{Id}_n \).

### 5.2 Moduli of objects of \( k(x^{\pm 1}, y^{\pm 1}) \), pair of pants, and fusion

Recall the lagrangian structure on the correspondence

\[
\text{Perf}_k[x^\pm 1] \coprod_{k[y^\pm 1]} \text{Perf}_k[y^\pm 1] \leftarrow \text{Perf}_k(x^\pm 1, y^\pm 1) \to \text{Perf}_k[z^\pm 1], \quad (5.3)
\]

given by applying the moduli of objects \( \text{Perf} \) to the Calabi–Yau cospan (3.7) (see [8, Theorem 5.5]). Using the other description from §3.3.1 of the Calabi–Yau cospan (3.7), and the
fact that the functor $\text{Map}((-)_B, \text{Perf})$ sends $\text{pt}$ to $\text{Perf}$, we obtain an alternative construction of the lagrangian correspondence (5.3). This is achieved by applying $\text{Map}((-)_B, \text{Perf})$ to the diagram

and then horizontally compose correspondences, as $\text{Perf}$ sends push-outs to pull-backs. Here we recall that $(-)$ denotes the orientation, respectively the symplectic structure, with inverted sign. A convenient replacement of the above diagram looks as follows:

Taking pushouts along the three horizontal correspondences above yields the following 1-oriented cospan/cobordism:
Note that the manifold at the center of the diagram is the pair of pants (see Figure 1).

![Diagram](image)

Figure 1: The decomposition of the pair of pants corresponding to (5.4), in 3d and 2d.

Using that \( \text{MAP}((-)_B, \text{Perf}) \) is a fully extended TFT [11], we have that the lagrangian correspondence (5.3) is obtained by applying \( \text{MAP}((-)_B, \text{Perf}) \) to the oriented cobordism given by the pair of pants, see [9, Theorem 4.8].

Hence, when restricting ourselves to the substacks of amplitude zero modules of fixed dimension \( n \), we get a lagrangian correspondence

\[
[GL_n/GL_n] \times [GL_n/GL_n] \leftrightarrow [(GL_n \times GL_n)/GL_n] \rightarrow [GL_n/GL_n]
\]

that coincides with the one given by applying \( \text{MAP}((-)_B, BGL_n) \) to the pair of pants (and using [9, Theorem 4.8]). It was shown by Safronov [25] that composition with this lagrangian correspondence gives back the fusion procedure from [1].
Remark 5.5. Notice that Perf sends the conjectural fully dualizable object $k$ in CY$_0$ from Remark 3.10 to the fully dualizable object Perf$_k$ in Lag$_n$. As a consequence Perf shall intertwine the conjecturally fully extended TFT from Remark 3.10 with the fully extended TFT $\text{Map}(\,-, \text{Perf}_k)$. What we have done above is following this guiding idea and applying it in an ad hoc way to the case of the pair-of-pants.

5.3 Open questions

Before applying reduction, we have a 1-shifted lagrangian structure on the morphism

$$\text{Perf}_{kQ_{loc}} \longrightarrow \text{Perf}_{k[x^\pm 1]}^{V(Q)}.$$ 

Fixing a dimension vector $\vec{n} \in (\mathbb{Z}_{\geq 0})^{V(Q)}$, one can consider the open substacks of dimension $\vec{n}$ amplitude 0 modules. This leads to a 1-shifted lagrangian structure on the morphism

$$[\text{Rep}(kQ_{loc}, \vec{n})/GL_{\vec{n}}] \longrightarrow [GL_{\vec{n}}/GL_{\vec{n}}].$$

(note that $\text{Rep}(kQ_{loc}, \vec{n}) \simeq D\text{Rep}(kQ_{loc}, \vec{n})$). Knowing from §5.1 that the 1-shifted symplectic structure on the target is the standard one on the adjoint quotient, we obtain that $\text{Rep}(kQ_{loc}, \vec{n})$ is a quasi-hamiltonian $GL_{\vec{n}}$-space. We conjecture that it coincides with the quasi-hamiltonian structure on the very same space from [34, 35, 36, 5].

Observe that it suffices to prove the conjecture for the simplest case $Q = A_2$. Indeed, in the above references the general case is obtained from the $A_2$ one by the fusion process of [1]. We proceeded in the same way in §4.2, and it follows from §5.2 that our fusion procedure coincides with the one of [1] for substacks of amplitude 0 modules.

In order to prove the conjecture for $A_2$, one could try to prove a similar statement directly at the noncommutative level. To achieve this, one would first have to rigorously prove that Van den Bergh’s noncommutative quasi-hamiltonian structures [36] naturally lead to relative Calabi–Yau structures (as was argued in the introduction).

Finally, we believe that our 1-Calabi–Yau structure on the dg-version of the multiplicative preprojective algebra shall give back the non-degenerate pairing appearing in [3] (in the case of a nodal curve with rational components) on the one hand, and could probably be recovered from [28] on the other hand. In both cases, it is very likely that the proof of the comparison will again go through a reduction to the $A_2$ quiver, using fusion.
