Abstract. When the Ohta-Kawasaki theory for diblock copolymers is applied to a bounded domain with the Neumann boundary condition, one faces the possibility of micro-domain interfaces intersecting the system boundary. In a particular parameter range, there exist stationary assemblies, stable in some sense, that consist of both perturbed discs in the interior of the system and perturbed half discs attached to the boundary of the system. The circular arcs of the half discs meet the system boundary perpendicularly. The number of the interior discs and the number of the boundary half discs are arbitrarily prescribed and their radii are asymptotically the same. The locations of these discs and half discs are determined by the minimization of a function related to the Green’s function of the Laplace operator with the Neumann boundary condition. Numerical calculations based on the theoretical findings show that boundary half discs help lower the energy of stationary assemblies.

1. Introduction. Morphological phases exist in multi-constituent physical or biological systems characterized by controlled growth. Common in these systems is that a deviation from homogeneity has a strong positive feedback on its further increase, and in the meantime a longer ranging confinement mechanism exists to limit increase and spreading. As a result, exquisitely structured patterns, known as morphological phases in materials science, arise in such systems as orderly outcomes of self-organization principles.

This study is to a large extent motivated by the diblock copolymer theory of Ohta and Kawasaki [8]. A diblock copolymer is a block copolymer whose molecular structure is a linear subchain of A-monomers grafted covalently to another subchain of B-monomers [2]. Because of the repulsion between the unlike monomers, the different type subchains tend to segregate, but as they are chemically bonded in chain molecules, segregation of subchains lead to local micro-phase separation: micro-domains rich in either A-monomers or B-monomers emerge as a result. These morphological structures determine the mechanical, optical, electrical, ionic, barrier and other physical properties.

Here we consider an ideal situation where micro-domains are clearly separated from each other by interfaces with zero width [7, 10, 4]. Mathematically, let \( D \) be a bounded domain in \( \mathbb{R}^2 \); \( D \) is assumed to be of class \( C^2 \), a condition necessary for many results in [9]. The energy functional is defined for every Lebesgue measurable subset \( \Omega \) of \( D \) whose Lebesgue measure is fixed at \( \omega |D| \):

\[
|\Omega| = \omega |D|. \quad (1.1)
\]

Here \( \omega \in (0, 1) \) is one of the two parameters in this problem. We write \( |\Omega| \) for the two dimensional Lebesgue measure of \( \Omega \) and \( |D| \) for the Lebesgue measure of \( D \). The free energy of \( \Omega \) is given by

\[
\mathcal{J}(\Omega) = P_D(\Omega) + \frac{\gamma}{2} \int_D |(-\Delta)^{-1/2}(\chi_\Omega - \omega)|^2 \, dx. \quad (1.2)
\]

Here \( P_D(\Omega) \) is the perimeter of \( \Omega \) in \( D \). In the case that \( \Omega \) is piecewise \( C^1 \), it is the length of the part of the boundary of \( \Omega \) that is inside \( D \). For a general \( \Omega \), see [11, 9] for the definition of \( P_D(\Omega) \). The part of the boundary of \( \Omega \) inside \( D \) is called the interface of \( \Omega \). It separates \( \Omega \) from \( D \setminus \Omega \).

To define the operator \((-\Delta)^{-1/2}\), let \( u \) be the solution of the following Poisson’s equation with the Neumann boundary condition:

\[
-\Delta u = f \quad \text{in} \ D, \quad \partial_\nu u = 0 \quad \text{on} \ \partial D, \quad \int_D u(x) \, dx = 0, \quad (1.3)
\]

where \( f \in L^2(D) \) and \( \int_D f(x) \, dx = 0 \). In (1.3) \( \partial_\nu \) stands for the outward normal derivative at \( \partial D \). Because the integral of \( f \) is 0, the partial differential equation with the boundary condition is solvable. The solution is unique up to an additive constant. The condition \( \int_D u(x) \, dx = 0 \) fixes this constant and gives us a unique solution. The map \( f \to u \) from the space of \( \{ f \in L^2(D) : \int_D f(x) \, dx = 0 \} \) to itself defines the operator \((-\Delta)^{-1} \). Since this operator is bounded and positive definite, it has a positive square root, which is \((-\Delta)^{-1/2}\) in (1.2). Like \((-\Delta)^{-1} \), \((-\Delta)^{-1/2}\) is a nonlocal operator. It acts on \( \chi_\Omega - \omega \) where \( \chi_\Omega \) is the characteristic function of \( \Omega \); \( \chi_\Omega(x) = 1 \) if \( x \in \Omega \) and \( \chi_\Omega(x) = 0 \) if \( x \in D \setminus \Omega \).

The notion of stationary sets in the most general sense is given in [9, (2.12)]. If the interface of \( \Omega \) is \( C^2 \), then \( \Omega \) is stationary if and only if it satisfies the following Euler-Lagrange equation and the intersection condition:

\[
K(\partial \Omega \cap D) + \gamma I(\Omega) = \lambda \quad \text{on} \ \partial \Omega \cap D, \quad (1.4)
\]

\[
\partial_\nu \Omega \cap D \perp \partial D \quad \text{at} \ \partial \Omega \cap D \cap \partial D. \quad (1.5)
\]

In (1.4), \( K(\partial \Omega \cap D) \) is the curvature of the curve \( \partial \Omega \cap D \) with respect to the normal vector inward towards \( \Omega \). The variable \( I(\Omega) \) is called the inhibitor of \( \Omega \). It is the solution of the Poisson’s equation (1.3) with \( f = \chi_\Omega - \omega \):

\[
-\Delta I(\Omega) = \chi_\Omega - w \quad \text{in} \ D, \quad \partial_\nu I(\Omega) = 0 \quad \text{on} \ \partial D, \quad \int_D I(\Omega)(x) \, dx = 0. \quad (1.6)
\]

The equation (1.5) asserts that the interface of \( \Omega \) is perpendicular to \( \partial D \) if the two meet.

One of the morphological phases observed in diblock copolymers is the cylindrical phase [2]. One monomer constituent is small in volume compared to the other monomer constituent. The minority monomers form many parallel cylinders in a system. Take \( D \) to be a cross section of the system. Then these cylinders give rise to an assembly \( \Omega \) of discs.
In [11] Ren and Wei showed the existence of disc assemblies as stationary sets of the functional $\mathcal{J}$. In such a stationary assembly, $\Omega$ is a union of multiple components, each of which is a perturbed disc located inside the domain $D$. Their result requires that the parameters $\omega$ and $\gamma$ be in a particular range where $\omega$ is sufficiently small and $\gamma$ is suitably large. Their proof also shows that these assemblies are stable in some sense. All the perturbed discs in their stationary assembly have approximately the same radius. If $\xi_{1,i}, \ldots, \xi_{n,i}$ are the centers of the discs in a stationary assembly found in [11], then $(\xi_{1,i}, \ldots, \xi_{n,i})$ is close to a minimum of a function $F_i$. This function is given by

$$F_i(\xi_1^i, \xi_2^i, \ldots, \xi_n^i) = \sum_{j \leq n_i} R(\xi_j^i, \xi_j^i) + 2 \sum_{j < k \leq n_i} G(\xi_j^i, \xi_k^i).$$

(1.7)

Here $n_i$ is the number of perturbed discs in the assembly, and $\xi_1^i, \ldots, \xi_n^i$ are distinct points in $D$. The subscript $i$ used here indicates that the points $\xi_j^i$ are in the interior of $D$, not on the boundary of $D$. This point will become important later.

The function $G$ is the Green’s function of $-\Delta$ on $D$ with the Neumann boundary condition; namely it satisfies

$$-\Delta_x G(x,y) = \delta(x) - \frac{1}{|D|} \text{ in } D, \quad \partial_{\nu_x} G(x,y) = 0 \text{ on } \partial D, \quad \int_D G(x,y) \, dx = 0 \quad (1.8)$$

for all $y \in D$. One writes $G$ as a sum of two parts:

$$G(x,y) = \frac{1}{2\pi} \log \frac{1}{|x - y|} + R(x,y),$$

(1.9)

where the first term is the fundamental solution of the $-\Delta$ operator, and the second term $R$, which appears in (1.7), is the regular part of $G$, a smooth function on $D \times D$.

One caveat in Ren and Wei’s work is that the discs in their stationary assemblies do not touch the boundary of $D$. One can avoid the issue of the domain boundary by assuming that $D$ is a rectangle and imposing the periodic boundary condition instead of the Neumann boundary condition; see [3, 6, 1, 5]. We prefer working with the more realistic Neumann boundary condition. In this case if the interface of a stationary set meets the domain boundary $\partial D$, (1.5) states that it does so perpendicularly.

Finding a stationary set whose interface meets the domain boundary is a difficult problem. The first non-trivial result came in our work [9]. When $\omega$ is sufficiently small and $\gamma$ is suitably large, there exists a stationary set shaped like a perturbed half disc, stable in some sense, whose boundary inside $D$ (a perturbed half circle) meets $\partial D$ perpendicularly. A crucial quantity introduced in [9] is termed $R_b(\xi_b, \xi_b)$, $\xi_b \in \partial D$, given by

$$R_b(\xi_b, \xi_b) = \lim_{y \in D, y \to \xi_b} G(\xi_b, y) - \frac{1}{\pi} \log \frac{1}{|\xi_b - y|}, \quad \xi_b \in \partial D.$$  

(1.10)

Note that the second term in 1.10 is twice the fundamental solution of $-\Delta$. If $\xi_{b,b} \in \partial D$ is the center of the perturbed half disc stationary set found in [9] and the parameters $\omega$ and $\gamma$ are in the same range as in this paper specified in Theorem 1.1, then $\xi_{b,b}$ is close to a minimum of the function

$$\xi_b \to R_b(\xi_b, \xi_b), \quad \xi_b \in \partial D.$$  

(1.11)

In this paper we construct stationary assemblies, stable in some sense, that contain both perturbed discs in the interior of $D$ and perturbed half discs that are
attached to $\partial D$. The perturbed discs and perturbed half discs in a stationary assembly have approximately the same radius, and the locations of their centers are also determined asymptotically.

Let $n_i$ and $n_b$ be non-negative integers. We use the convention that the subscript $i$ is attached to quantities related to the interior discs of an assembly, and the subscript $b$ is attached to quantities related to the boundary half discs. For a stationary assembly of $n_i$ perturbed discs inside $D$ and $n_b$ perturbed half discs attached to $\partial D$, it is convenient to introduce the average radius as a parameter in place of $\omega$; namely let $\rho > 0$ so that

$$\omega|D| = n_i \pi \rho^2 + \frac{n_b \pi \rho^2}{2}. \quad (1.12)$$

Now $\rho$ and $\gamma$ are the two parameters of our problem.

**Theorem 1.1.** Let $n_i$, $n_b$ be non-negative integers. There exists $\sigma > 0$ depending on $n_i$, $n_b$, and $D$, and for every $\epsilon > 0$ there exists $\delta > 0$ depending on $\epsilon$, $n_i$, $n_b$, and $D$, such that if

1. $\rho < \delta$,
2. $\frac{1 + \epsilon}{\rho \log \frac{\delta}{\rho}} < \gamma < \frac{\sigma}{\rho}$,

then $J$ admits a stationary assembly $\Omega_*$ of $n_i$ perturbed interior discs and $n_b$ perturbed boundary half discs, satisfying the constraint $|\Omega_*| = n_i \pi \rho^2 + \frac{n_b \pi \rho^2}{2}$.

Define a function

$$F(\xi_1^i, \ldots, \xi_n^i, \xi_1^b, \ldots, \xi_n^b) = \sum_{j \leq n_i} R(\xi_j^i, \xi_j^i) + \frac{1}{4} \sum_{j \leq n_b} R_b(\xi_j^b, \xi_j^b) + 2 \sum_{j < k \leq n_i} G(\xi_j^i, \xi_k^i)$$

$$+ \frac{1}{2} \sum_{j < k \leq n_b} G(\xi_j^b, \xi_j^b) + \sum_{j \leq n_i, k \leq n_b} G(\xi_j^i, \xi_k^b) \quad (1.13)$$

in the domain

$$\Xi = \left\{ \xi = (\xi_1^i, \ldots, \xi_n^i, \xi_1^b, \ldots, \xi_n^b) : \xi_j^i \in D \text{ for } j = 1, \ldots, n_i, \xi_j^i \neq \xi_k^i \text{ if } j \neq k, \right. \xi_k^b \in \partial D \text{ for } j = 1, \ldots, n_b, \xi_j^i \neq \xi_k^b \text{ if } j \neq k \right\}. \quad (1.14)$$

Because $G(x, y) \to 0$ if $|x - y| \to 0$ and $R(z, z) \to 0$ if $z \to \partial D$, $F(\xi) \to 0$ if $\xi \to \partial \Xi$. More precisely, for every $M \in \mathbb{R}$ there exists a compact subset $K$ of $\Xi$ such that $F(\xi) > M$ whenever $\xi \in \Xi \setminus K$. In particular $F$ admits a minimum in $\Xi$. The next theorem gives the sizes and the locations of the discs and half discs in the stationary assemblies.

**Theorem 1.2.** Let $\xi_{j, i}^i \in D$ and $\xi_{k, b}^b \in \partial D$ be the centers and $r_{j, i}^i$ and $r_{k, b}^b$ be the radii of the perturbed discs and half discs in the stationary assembly $\Omega_*$ of Theorem 1.1.

1. As $\rho \to 0$, $\frac{r_{j, i}^i}{\rho} \to 1$ and $\frac{r_{k, b}^b}{\rho} \to 1$.
2. As $\rho \to 0$, every limit point of $(\xi_{1, i}^1, \ldots, \xi_{n, i}^n, \xi_{1, b}^1, \ldots, \xi_{n, b}^n)$ along a subsequence is a minimum of $F$.

This stationary assembly is stable in some sense.

These two theorems contain very detailed information about the stationary assemblies. Figure 1 shows several stationary assemblies when $D$ is the unit disc. The range for $n_i$ is the set of integers from 0 to 10 and the range for $n_b$ is the set of
even integers from 0 to 20. In all these assemblies \( n_i + \frac{n_b}{2} = 10 \). The locations of the discs and half discs are determined by numerical minimization of \( F \).

Probably the most important reason to study stationary assemblies with both interior discs and boundary half discs is to see whether one can lower the free energy of a stationary assembly of only interior discs by replacing some interior discs by some boundary half discs. In the proofs of the main theorems, one obtains detailed information on the stationary assemblies. This allows us to compare their energy. We present examples where stationary assemblies with only interior discs have higher energy than some stationary assemblies with both interior discs and boundary half discs.

The proofs of Theorems 1.1 and 1.2 are organized as follows. In section 2 one constructs approximately stationary assemblies of interior discs and boundary half discs. The centers and radii of the discs and half discs are to be determined. In
section 3 one formulates a problem $S(\Phi) = 0$ in a Hilbert space. A solution to this problem solves the Euler-Lagrange equation (1.4) up to the constant $\lambda$. Namely that a solution of $S(\Phi) = 0$ represents a set $\Omega$ of multiple components. On the boundary of each component, the equation (1.4) holds. However the constant $\lambda$ varies from component to component.

To solve $S(\Phi) = 0$, one actually solves a weaker problem in section 4: $\Pi S(\Phi) = 0$ where $\Pi$ is a projection operator. Here one uses a fixed point argument with the help of the invertibility of a linear operator. The resulting solutions are an improvement of the previously constructed approximately stationary assemblies. Finally in section 5 one chooses centers and radii properly so that the solution of $\Pi S(\Phi) = 0$ is also a solution of $S(\Phi) = 0$ and a solution of (1.4).

Section 6 is devoted to the question of the advantage of stationary assemblies with both interior discs and boundary half discs over stationary assemblies with just interior discs.

2. Approximately stationary assemblies. We start with a construction of an assembly of exact discs inside $D$ and perturbed half discs attached to $\partial D$. Let $\alpha > 0$, $\beta \in (0,1)$, and set

$$\Xi_\alpha = \{ \xi = (\xi^1_1, \ldots, \xi^n_1, \xi^1_b, \ldots, \xi^n_b) : \xi^i_j \in D, \text{dist}(\xi^i_j, \partial D) \geq \alpha, \quad |\xi^i_j - \xi^k_l| \geq 2\alpha \forall j \neq k, \xi^i_j \in \partial D, \quad |\xi^i_j - \xi^k_l| \geq 2\alpha \forall j \neq k \}$$

$$W_\beta = \{ r = (r^1_1, \ldots, r^n_1, r^1_b, \ldots, r^n_b) : r^i_j, r^i_b \in [(1-\beta)\rho, (1+\beta)\rho], \sum_{j \leq n_i} \pi(r^j)^2 + \sum_{j \leq n_b} \frac{\pi(r^j)^2}{2} = n_i \pi \rho^2 + \frac{n_b \pi \rho^2}{2} \}.$$ (2.1)

Note that we write $\xi$ for $(\xi^1_1, \ldots, \xi^n_1, \xi^1_b, \ldots, \xi^n_b)$ and $r$ for $(r^1_1, \ldots, r^n_1, r^1_b, \ldots, r^n_b)$ in this paper. The number $\alpha$ is small enough so that

$$\min_{\xi \in \Xi_\alpha} F(\xi) = \inf_{\xi \in \Xi \backslash \Xi_\alpha} F(\xi);$$ (2.3)

the number $\beta$ is also small so that for all $t \in [(1-\beta)^2, (1+\beta)^2]$, $g''(t) > 0$ where $g(t) = \frac{8\sqrt{t}}{1+\epsilon} + t^2$. (2.4)

In (2.3) the set $\Xi$ is the domain of $F$, given in (1.14); in (2.4) $\epsilon > 0$ is the number in the statement of Theorem 1.1. Note that, since $F(\xi) \rightarrow \infty$ if $\xi \rightarrow \partial \Xi$, (2.3) holds if $\alpha$ is sufficiently small. Also, since $g''(1) = -\frac{2}{1+\epsilon} + 2 > 0$, a small $\beta$ can be found so that (2.4) holds. The significance of the conditions (2.3) and (2.4) will emerge later in the paper. For now we only think of $\alpha$ and $\beta$ as two small fixed numbers.

Let $\xi = (\xi^1_1, \ldots, \xi^n_1, \xi^1_b, \ldots, \xi^n_b) \in \Xi_\alpha$ and $r = (r^1_1, \ldots, r^n_1, r^1_b, \ldots, r^n_b) \in W_\beta$. We first make $n_i$ discs centered at $\xi^i_j$ of radius $r^j$:

$$E^i_j = \{ x \in \mathbb{R}^2 : |x - \xi^i_j| < r^j \}.$$ (2.5)

Before making perturbed half discs attached to the domain boundary $\partial D$, one needs to set up coordinate frames on $\partial D$. Let

$$t \rightarrow r(t)$$ (2.6)
be a parametrization of a part of \( \partial D \). We sometimes identify \( t \) with \( \mathbf{r}(t) \) if no confusion arises, and write \( t \in \partial D \). Let \( \mathbf{t}(t) \) and \( \mathbf{n}(t) \) be the unit tangent and normal vectors of \( \partial D \) at \( t \) respectively. Assume that
\begin{enumerate}
  \item \( \mathbf{t}(t) = \frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} \),
  \item \( \mathbf{n}(t) = i \mathbf{t}(t) \), i.e. \( (\mathbf{t}(t), \mathbf{n}(t)) \) is a right-handed coordinate system,
  \item \( \mathbf{n}(t) \) points inward with respect to \( D \).
\end{enumerate}

In this paper to simplify notation, \( \mathbb{R}^2 \) is identified with \( \mathbb{C} \). Then \( i \mathbf{t}(t) \), the counterclockwise 90 degree rotation of \( \mathbf{t}(t) \), is just the complex product of \( i \) and \( \mathbf{r}(t) \), the latter viewed as a complex number. The arc length variable \( s \) measured from a fixed point on \( \partial D \) is given by
\[
\frac{ds}{dt} = |\mathbf{r}'(t)|. \tag{2.7}
\]
The (signed) curvature \( \kappa \) of \( \partial D \) is defined with respect to the inward normal vector \( \mathbf{n} \) so that
\[
\frac{dt}{ds} = \kappa \mathbf{n}, \quad \frac{d\mathbf{n}}{ds} = -\kappa \mathbf{t}. \tag{2.8}
\]
With \( \mathbf{r}(t) \) being the center, \( \mathbf{t}(t) \) and \( \mathbf{n}(t) \) form a right-handed orthonormal frame so that any point \( x \) inside \( D \) or outside \( D \) can be described by
\[
x = \mathbf{r}(t) + (\mathbf{t}(t), \mathbf{n}(t)) \begin{pmatrix} p_1 \\ p_2 \end{pmatrix}, \tag{2.9}
\]
where \( p_1 \) and \( p_2 \) are the coordinates of \( x \) under this frame. The transformation \( T_t \) is defined to be
\[
T_t : p = \begin{pmatrix} p_1 \\ p_2 \end{pmatrix} \rightarrow \mathbf{r}(t) + (\mathbf{t}(t), \mathbf{n}(t)) \begin{pmatrix} p_1 \\ p_2 \end{pmatrix}, \tag{2.10}
\]
so that \( x = T_t(p) \). We call \( x \) a point in the original space and \( p \) the coordinate vector of \( x \) under the \((\mathbf{t}(\xi), \mathbf{n}(\xi))\) frame.

Introduce a function \( f \) which is locally the graph of \( \partial D \) under the \((\mathbf{t}(t), \mathbf{n}(t))\) frame. More precisely, for \( \tau \) near \( t \) there exist \( p_1 \) and \( p_2 \) such that \( \mathbf{r}(\tau) = \mathbf{r}(t) + p_1 \mathbf{t}(t) + p_2 \mathbf{n}(t) \). The correspondence \( p_1 \rightarrow p_2 \) defines a function whose graph is \( \partial D \) near \( t \) under the \((\mathbf{t}(t), \mathbf{n}(t))\) frame. Since this function depends on the fixed point \( t \), we treat it as a function of two variables, \( p_1 \) and \( t \): \( p_2 = f(p_1, t) \). With \( f \) we have
\[
\mathbf{r}(\tau) = \mathbf{r}(t) + (\mathbf{t}(t), \mathbf{n}(t)) \begin{pmatrix} p_1 \\ f(p_1, t) \end{pmatrix}. \tag{2.11}
\]
Note that
\[
f(0, t) = D_1 f(0, t) = 0, \quad \text{for all } t \in \partial D. \tag{2.12}
\]
In this paper we write \( D_1 f \) for the first partial derivative of \( f \) with respect to its first argument, and \( D_2^2 f \) for the second partial derivative of \( f \) with respect to its first argument, etc.

The function \( f \) also provides a way to locally flatten the domain \( D \). Define a transformation \( Q_t \) by
\[
Q_t \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \begin{pmatrix} u_1 \\ u_2 + f(u_1, t) \end{pmatrix}. \tag{2.13}
\]
The derivative of \( Q_t \) is
\[
\frac{DQ_t}{Du} = \begin{bmatrix} 1 & 0 \\ D_1 f(u_1, t) & 1 \end{bmatrix}, \quad \text{and} \quad \left. \frac{DQ_t}{Du} \right|_{u=0} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{2.14}
\]
The inverse of \( Q_t \) is
\[
Q_t^{-1} \left( \begin{array}{c} p_1 \\ p_2 \\
\end{array} \right) = \left( \begin{array}{c} p_1 \\ p_2 - f(p_1, t) \\
\end{array} \right).
\tag{2.15}
\]

Now we are ready to make perturbed half discs attached to \( \partial D \). For each pair of \( \xi_i^j \) and \( r_i^b \) let
\[
E_b^j = \{ x = T_{\xi_i^j} \circ Q_{\xi_i^j}(u) : |u| < r_i^b, \ u = (u_1, u_2), \ u_2 > 0 \}. \tag{2.16}
\]

With these discs and perturbed half discs one obtains an assembly
\[
E = \left( \bigcup_{j \leq n} E_b^j \right) \cup \left( \bigcup_{j \leq n_b} E_b^j \right). \tag{2.17}
\]
The discs and half discs in \( E \) are non-overlapping if \( \rho \) is small because of the definition of \( \Xi_\alpha \). We use \( E \) as an approximate solution to the equations (1.4) and (1.5). The energy of \( E \) is estimated below. Its proof, which we omit, is a combination of [11, Lemma 3.2] and [9, Lemma 2.3].

**Lemma 2.1.**
\[
J(E) = \sum_{j \leq n} 2\pi r_i^j + \sum_{j \leq n_b} \pi r_i^b + O(\rho^2)
+ \frac{\gamma}{2} \left[ \sum_{j \leq n} \left( \frac{\pi(r_i^j)^4}{2} \log \frac{1}{r_i^j} + \frac{\pi(r_i^j)^4}{8} + \left( \frac{\pi(r_i^j)^2}{2} \right)^2 R(\xi_i^j, \xi_i^j) \right) \right]
+ \sum_{j \leq n_b} \left( \frac{\pi(r_i^b)^4}{4} \log \frac{1}{r_i^b} + \frac{\pi(r_i^b)^4}{16} + \left( \frac{\pi(r_i^b)^2}{2} \right)^2 R_b(\xi_i^b, \xi_i^b) \right)
+ 2 \sum_{j \leq n, k \leq n_b} \left( \frac{\pi(r_i^j)^2(r_i^k)^2}{2} \right) G(\xi_i^j, \xi_i^k) + 2 \sum_{j \leq n, k \leq n_b} \left( \frac{\pi(r_i^j)^2}{2} \right) G(\xi_i^j, \xi_i^k)
+ 2 \sum_{j \leq n, k \leq n_b} \pi(r_i^j)^2 \left( \frac{\pi(r_i^k)^2}{2} \right) G(\xi_i^j, \xi_i^k) + O(\gamma \rho^2).
\]

3. **A Hilbert space.** Lemma 3.1 below is a standard result on the variation of the length of a curve, and Lemma 3.2 gives a formula for the variation of an integral on a set. Following the two lemmas, the first variation of \( J \) is derived in Lemma 3.3.

Suppose that \( R(\theta), \ \theta \in [a, b] \), is a parametrized curve. The unit tangent vector of \( R \) is \( T \) given by
\[
T(\theta) = \frac{R'(\theta)}{|R'(\theta)|}. \tag{3.1}
\]
Let \( N \) be a unit normal vector to \( R \) and \( K \) be the curvature of \( R \), so that \( KN \) is the curvature vector of \( R \). Moreover
\[
\frac{dT}{ds} = KN, \tag{3.2}
\]
where \( ds = |R'(\theta)|d\theta \) is the length element. A deformation of \( R \) is a family of curves \( R_\varepsilon \), parametrized by \( \varepsilon \) in a neighborhood of 0, so that \( R_0 = R \).

**Lemma 3.1.** Let \( R(\theta), \ \theta \in [a, b] \), be a curve and \( R_\varepsilon(\theta) \) be a deformation of \( R(\theta) \). Denote by \( X \) the infinitesimal element of the deformation \( R_\varepsilon \):
\[
X(\theta) = \frac{\partial R_\varepsilon(\theta)}{\partial \varepsilon} |_{\varepsilon = 0}.
\]
Then
\[
\frac{d}{d\varepsilon} \bigg|_{\varepsilon = 0} \int_a^b |R_\varepsilon'| d\theta = T \cdot X \bigg|_{a}^{b} - \int_a^b KN \cdot X \, ds,
\]
where \( d \) is the arc length element of \( R_\varepsilon \) and \( N \) is the unit normal vector to \( R_\varepsilon \).
and thus set represented by elements in a Hilbert space. General assembly $\Omega$ of perturbed discs and half discs. Such perturbations will be

Also map it to $E$ and this set is a perturbation of $E$.

\[ \text{Lemma 3.3.} \] Suppose that a bounded domain $\Omega$ is enclosed by a curve $\partial \Omega$, and $\Omega_\varepsilon$ is a deformation of $\Omega$. Let $X$ be the infinitesimal element of the deformation of $\partial \Omega$. Then

\[ \left. \frac{d}{d\varepsilon} \right|_{\varepsilon=0} \int_{\Omega_\varepsilon} f(x) \, dx = - \int_{\partial \Omega} f(x) N \cdot X \, ds \]

where $N$ is the inward unit normal vector on $\partial \Omega$.

Let us consider a set $\Omega$ with $n_i$ components $\Omega^i_i$ inside $D$ and $n_b$ components $\Omega^b_b$ that touch the boundary of $D$. The first variation of this set is given by the following lemma.

\[ \text{Lemma 3.3.} \] Let $\Omega_\varepsilon$ be a deformation of a set $\Omega$ which consists of interior components $\Omega^i_i$ and boundary components $\Omega^b_b$ in $D$ with piecewise $C^1$ interface parametrized by $R^i_i(\theta)$, $\theta \in [a, b]$, $j = 1, \ldots, n$, $\mu = i, b$. Then

\[ \frac{d\phi(\Omega)}{d\varepsilon} \bigg|_{\varepsilon=0} = - \sum_{j=1}^{n_b} \int_{\partial \Omega^j_b \cap D} (K(\partial \Omega \cap D) + \gamma I(\Omega)) N^j_b \cdot X^j_b \, ds \]

Also

\[ \frac{d|\Omega_\varepsilon|}{d\varepsilon} \bigg|_{\varepsilon=0} = - \sum_{j \leq n_b, \mu = i, b} \int_{\partial \Omega^j_j \cap D} N^j_\mu \cdot X^j_\mu \, ds. \]

In this section we find a way to perturb the approximate solution $E$ to a more general assembly $\Omega$ of perturbed discs and half discs. Such perturbations will be represented by elements in a Hilbert space.

To perturb an interior component $E^i_i$ of $E$ we need a $2\pi$-periodic function $\phi^i_i$ and thus set

\[ P^i_i = \left\{ te^{i\theta} : \theta \in S^1, t \in [0, \sqrt{(r^i_i)^2 + 2\phi^i_i(\theta)}] \right\}. \quad (3.3) \]

The circle $S^1$ is used to denote the interval $[0, 2\pi]$ with identified end points. Shift $P^i_i$ by $\xi^i_i$ to

\[ \Omega^i_i = \xi^i_i + P^i_i, \quad (3.4) \]

and this set is a perturbation of $E^i_i$. To perturb a boundary component $E^b_b$, let

\[ P^b_b = \left\{ te^{i\theta} : \theta \in (0, \pi), t \in [0, \sqrt{(r^b_b)^2 + 2\phi^b_b(\theta)}] \right\}, \quad (3.5) \]

and then map it to

\[ \Omega^b_b = T_{\xi^b_b} \circ Q_{\xi^b_b}(P^b_b) \quad (3.6) \]

to yield a perturbation of $E^b_b$. Now set

\[ \Omega = \left( \bigcup_{j \leq n_i} \Omega^i_i \right) \cup \left( \bigcup_{j \leq n_b} \Omega^b_b \right). \quad (3.7) \]
Obviously $\phi_i^j$ and $\phi_0^j$ need to be small compared to $(r_i^j)^2$ and $(r_0^j)^2$ respectively for the definitions (3.3) and (3.5) to be meaningful. We also need some smoothness for $\phi_i^j$ and $\phi_0^j$ for $J(\Omega)$ to be defined. Let us start with a Hilbert space

\[
\mathcal{Z} = \left\{ \Phi = (\phi_1^1, \ldots, \phi_1^{n_1}, (\phi_0^1, \phi_1^1), \ldots, (\phi_0^{n_b}, \phi_1^{n_b})) : \\
\phi_i^j \in L^2(S^1), \int_0^{2\pi} \phi_i^j = 0, \ j = 1, \ldots, n_i, \\
\phi_0^j \in L^2(0, \pi), \ \phi_0^j, \phi_n^j \in \mathbb{R}, \ \int_0^\pi \phi_0^j = 0, \ j = 1, \ldots, n_b \right\}. \tag{3.8}
\]

The inner product in $\mathcal{Z}$ is

\[
\langle \Phi, \Psi \rangle = \sum_{j \in N_i} \int_0^{2\pi} \phi_i^j \psi_i^j + \sum_{j \in N_b} \left( \phi_0^j \psi_0^j + \phi_n^j \psi_n^j + \int_0^\pi \phi_0^j \psi_0^j \right). \tag{3.9}
\]

The constraints

\[
\int_0^{2\pi} \phi_i^j = 0, \ j = 1, \ldots, n_i, \ \int_0^\pi \phi_0^j = 0, \ j = 1, \ldots, n_b \tag{3.10}
\]

ensure that the area of $\Omega_i^j$ is fixed at $\pi(r_i^j)^2$ and the area of $\Omega_0^j$ is fixed at $\pi(r_0^j)^2/2$, since

\[
|\Omega_i^j| = \int_0^{2\pi} \int_0^{\sqrt{(r_i^j)^2 + 2\phi_i^j}} r \, dr \, d\theta = \pi(r_i^j)^2 + \int_0^{2\pi} \phi_i^j \, d\theta = \pi(r_i^j)^2 \\
|\Omega_0^j| = \int_0^\pi \int_0^{\sqrt{(r_0^j)^2 + 2\phi_0^j}} r \, dr \, d\theta = \frac{\pi(r_0^j)^2}{2} + \int_0^\pi \phi_0^j \, d\theta = \frac{\pi(r_0^j)^2}{2}.
\]

Note that $|\Omega_i^j| = |P_i^j|$ since the Jacobian of $Q_{\phi_i^j}$ equals 1 by (2.14).

Next is a subspace $\mathcal{Y}$ of $\mathcal{Z}$,

\[
\mathcal{Y} = \left\{ \Phi \in \mathcal{Z} : \ \phi_i^j \in H^1(S^1), \ \phi_0^j \in H^1(0, \pi), \ \phi_0^j = \phi_0^j(0), \ \phi_n^j = \phi_n^j(\pi) \right\}. \tag{3.11}
\]

Let $\xi$ and $r$ be held fixed. Then the set $\Omega$ is represented by $\Phi$ and $J$ is viewed as a functional of $\Phi$. In this setting, the domain of $J$ is a neighborhood of the 0 element in $\mathcal{Y}$:

\[
\text{Dom}(J) = \{ \Phi \in \mathcal{Y} : \|\Phi\|_\mathcal{Y} < br^2 \}, \tag{3.12}
\]

where $b$ is a sufficiently small positive constant, independent of $\rho$, so that

\[
(r_i^j)^2 + 2\phi_i^j(\theta) > 0, \ \text{for all} \ \theta \in S^1, \ (r_0^j)^2 + 2\phi_0^j(\theta) > 0, \ \text{for all} \ \theta \in (0, \pi). \tag{3.13}
\]

This makes (3.3) and (3.5) geometrically meaningful definitions of perturbed discs and half discs respectively.

It is easy to make a deformation in $\mathcal{Y}$. Let $\Phi \in \text{Dom}(J)$ and $\Psi \in \mathcal{Y}$. Then

\[
\Phi \rightarrow \Phi + \varepsilon \Psi \tag{3.14}
\]

defines a deformation of $\Phi$. Consequently it gives rise to a deformation $\Omega_\varepsilon$, represented by $\Phi + \varepsilon \Psi$, of the assembly $\Omega$ represented by $\Phi$. This deformation leads to the first variation

\[
\frac{d}{d\varepsilon} \bigg|_{\varepsilon=0} J(\Phi + \varepsilon \Psi). \tag{3.15}
\]

Another subspace $\mathcal{X}$ of $\mathcal{Z}$ is

\[
\mathcal{X} = \left\{ \Phi \in \mathcal{Z} : \ \phi_i^j \in H^2(S^1), \ \phi_0^j \in H^2(0, \pi), \ \phi_0^j = \phi_0^j(0), \ \phi_n^j = \phi_n^j(\pi) \right\}. \tag{3.16}
\]
The three spaces are nested: $\mathcal{X} \subset \mathcal{Y} \subset \mathcal{Z}$. In the case that $\Phi \in \mathcal{X}$, integration by parts yields

$$\frac{d}{d\varepsilon} \bigg|_{\varepsilon=0} J(\Phi + \varepsilon \Psi) = \langle S(\Phi), \Psi \rangle.$$  
(3.17)

In (3.17) $S$ is a nonlinear operator defined on

$$\text{Dom}(S) = \{ \Phi \in \mathcal{X} : \| \Phi \|_\mathcal{X} < b \rho^2 \}$$  
(3.18)

where $b$ is the same as the one in (3.12). More specifically

$S = (S^1_1, \ldots, S^1_n, (S^2_0, S^2_\pi, S^2_b), \ldots, (S^n_0, \ldots, S^n_0, S^n_b))$  
(3.19)

where

$$S^j_0(\Phi) = K(\partial \Omega \cap D)(R^j_i(\theta)) + I(\Omega)(R^j_i(\theta)) - \lambda^j_i(\Phi)$$  
(3.20)

$$S^j_0(\Phi) = -\bar{\bar{T}}^j(0) \cdot \frac{1}{\sqrt{(r^j_0)^2 + 2\phi^j_0(0)}} \left( D_1 f \left( \sqrt{(r^j_0)^2 + 2\phi^j_0(0)}, \xi^j_0 \right) \right)$$  
(3.21)

$$S^j_\pi(\Phi) = \bar{T}^j(\pi) \cdot \frac{1}{\sqrt{(r^j_\pi)^2 + 2\phi^j_\pi(\pi)}} \left( -D_1 f \left( -\sqrt{(r^j_\pi)^2 + 2\phi^j_\pi(\pi)}, \xi^j_\pi \right) \right)$$  
(3.22)

$$S^j_b(\Phi) = K(\partial \Omega \cap D)(R^j_b(\theta)) + I(\Omega)(R^j_b(\theta)) - \lambda^j_b(\Phi).$$  
(3.23)

The range of $S$ is a subspace of $\mathcal{Z}$.

Here $\Omega$ is the assembly represented by $\Phi$. The interface of the component $\Omega^j_i$ (resp. $\Omega^j_b$) is parametrized by $R^j_i$ (resp. $R^j_b$):

$$R^j_i(\theta) = \xi^j_i + \sqrt{(r^j_i)^2 + 2\phi^j_i(\theta)e^{i\theta}}, \quad j = 1, \ldots, n_i$$  
(3.24)

$$R^j_b(\theta) = T^j_i \circ Q^j_i \left( \sqrt{(r^j_b)^2 + 2\phi^j_b(\theta)e^{i\theta}} \right), \quad j = 1, \ldots, n_b.$$  
(3.25)

The tangent and normal vectors of $R^j_\mu$ are denoted $T^j_\mu$ and $N^j_\mu$.

For $R^j_b$, let $\bar{R}^j_b$ be the parametrization under the $(t(\xi^j_b), n(\xi^j_b))$ frame so that

$$\bar{R}^j_b(\theta) = Q^j_i(\sqrt{(r^j_b)^2 + 2\phi^j_b(\theta)e^{i\theta}}), \quad R^j_b(\theta) = T^j_i(\bar{R}^j_b(\theta)).$$  
(3.26)

The tangent and normal vectors of $\bar{R}^j_b$ are denoted $\bar{T}^j_b$ and $\bar{N}^j_b$ respectively.

In (3.20) and (3.23), $\lambda^j_\mu(\Phi)$ are numbers chosen such that

$$\int_0^{2\pi} S^j_\mu(\Phi) d\theta = 0, \quad j = 1, \ldots, n_i, \quad \int_0^{\pi} S^j_b(\Phi) d\theta = 0, \quad j = 1, \ldots, n_b.$$  
(3.27)

If an assembly $\Omega$ represented by $\Phi$ is a solution of $S(\Phi) = 0$, then $\Omega$ satisfies the equations

$$K(\partial \Omega^j_i) + \gamma I(\Omega) = \lambda^j_i \quad \text{on} \quad \partial \Omega^j_i, \quad j = 1, \ldots, n_i$$  
(3.28)

$$K(\partial \Omega^j_b) + \gamma I(\Omega) = \lambda^j_b \quad \text{on} \quad \partial \Omega^j_b \cap D, \quad j = 1, \ldots, n_b$$  
(3.29)

$$T^j_b \perp \partial D \quad \text{on} \quad \partial D, \quad j = 1, \ldots, n_b.$$  
(3.30)

Since the $\lambda^j_\mu$’s vary from component to component, $\Omega$ is generally not a solution of (1.4).

If $R_\varepsilon$ is a deformation of $R$ such that $R_0 = R$, then the infinitesimal element is

$$X^j_\mu = \left. \frac{\partial R^j_\varepsilon}{\partial \varepsilon} \right|_{\varepsilon=0}, \quad X^j_b = \left. \frac{\partial \bar{R}^j_\varepsilon}{\partial \varepsilon} \right|_{\varepsilon=0}.$$
This deformation may be more general than the one considered in (3.14). Nevertheless the end points of each perturbed half disc can only move along the boundary of D in this deformation. Define \( X^j_i \) and \( X^j_b \) in \( \mathbb{R} \) by

\[
X^j_i(0) = \frac{X^j_i}{\sqrt{(r^j_i)^2 + 2\phi^j_i(0)}} \left( \frac{1}{D_1 f(\sqrt{(r^j_i)^2 + 2\phi^j_i(0)}, \xi^j_i)} \right),
\]

\[
X^j_b(0) = \frac{X^j_b}{\sqrt{(r^j_b)^2 + 2\phi^j_b(0)}} \left( \frac{1}{D_1 f(-\sqrt{(r^j_b)^2 + 2\phi^j_b(0)}, \xi^j_b)} \right).
\]

The first variation formula in Lemma 3.3 can now be written as

\[
\frac{\partial J(\Phi)}{\partial \varepsilon} \bigg|_{\varepsilon=0} = -\sum_{j \leq n_i} \int_{\partial \Omega^j_i} (S^j_i(\Phi) + \lambda^j_i(\Phi))N^j_i \cdot X^j_i \, ds
\]

\[
+ \sum_{j \leq n_b} \left( S^j_b(\Phi)X^j_i + S^j_i(\Phi)X^j_b - \int_{\partial \Omega^j_i \cap D} (S^j_b(\Phi) + \lambda^j_b(\Phi))N^j_b \cdot X^j_b \, ds \right).
\]

(3.33)

The next lemma gives an estimate of \( S(0) \), where the element 0 in \( \mathcal{X} \) represents the approximate assembly \( E \). The proof of this lemma is a combination of [11, Lemma 3.1] and [9, Lemma 4.5].

**Lemma 3.4.**

\[
S^j_i(0) = \frac{1}{r^j_i} + \gamma \left[ \frac{(r^j_i)^2}{2} \log \frac{1}{r^j_i} + \pi (r^j_i)^2 R(\xi^j_i, \xi^j_i) + \sum_{k \leq n_i, k \neq j} \pi (r^k_i)^2 G(\xi^j_i, \xi^k_i) \right.
\]

\[
+ \sum_{k \leq n_b} \frac{\pi (r^k_b)^2}{2} G(\xi^j_i, \xi^k_b) + O(\rho^3) \right) - \lambda^j_i(0)
\]

(3.34)

\[
S^j_b(0) = O(1)
\]

(3.35)

\[
S^j_i(0) = O(1)
\]

(3.36)

\[
S^j_b(0) = \frac{1}{r^j_b} + O(1) + \gamma \left[ \frac{(r^j_b)^2}{2} \log \frac{1}{r^j_b} + \frac{\pi (r^j_b)^2}{2} R_b(\xi^j_b, \xi^j_b) + \sum_{k \leq n_b, k \neq j} \frac{\pi (r^k_b)^2}{2} G(\xi^j_b, \xi^k_b) \right.
\]

\[
+ \sum_{k \leq n_i} \pi (r^k_i)^2 G(\xi^j_b, \xi^k_i) + O(\rho^3) \right) - \lambda^j_b(0).
\]

(3.37)

Note that Lemma 3.4 implies the following.

**Lemma 3.5.** \( \|S(0)\|_Z = O(1) \).

It is not realistic to solve the equation \( S(\Phi) = 0 \) for any given \( \xi \). Instead we will solve a weaker equation first. Let us define three more subspaces at this point.

\[
\mathcal{Z}_0 = \{ \Phi \in \mathcal{Z} : \int_0^{2\pi} \phi^j_0 \cos \theta = \int_0^{2\pi} \phi^j_0 \sin \theta = 0, \; j = 1, ..., n_i, \}
\]

\[
\phi^j_0 - \phi^j_n + \int_0^{\pi} \phi^j_b \cos \theta = 0, \; j = 1, ..., n_b \}
\]

(3.38)

\[
\mathcal{Y}_0 = \mathcal{V} \cap \mathcal{Z}_0
\]

(3.39)

\[
\mathcal{X}_0 = \mathcal{X} \cap \mathcal{Z}_0.
\]

(3.40)
The projection from $\mathcal{Z}$ to $\mathcal{Z}_0$ is denoted $\Pi$, defined by the inner product (3.9). One first looks for an element in $\lambda'_j$ that solves $\Pi S(\Phi) = 0$. Later one finds some special $\xi$ for which $S(\Phi) = 0$.

When $S(\Phi) = 0$ is solved for all $r \in W_\beta$, one finds some special $r$ such that in the equations (3.28-3.30) for the solution of $S(\Phi) = 0$ associated with this particular $r$, all the $\lambda'_j$ are the same and hence (1.4) holds.

Because of (3.10), if $\Phi$ is represented by $\Phi \in \mathcal{Z}$, the measure of $\Omega^i_\beta$ is $\pi (r^i_\beta)^2$ and the measure of $\Omega^j_\beta$ is $\pi (r^j_\beta)^2$. If in addition $\Phi \in \mathcal{Z}_0$, one interprets that $\xi^j_1$ is the center of the perturbed disc $\Omega^j_\beta$ and that $\xi^j_2$ is the center of the perturbed half disc $\Omega^j_\beta$. The subspace $\mathcal{Z}_0$ gives precise meanings of the center and radius of a perturbed disc or half disc. When $\Phi \in \mathcal{Z}_0$, we call the $\xi^j_1$’s and the $\xi^j_2$’s the centers of the perturbed discs and half discs in $\Phi$ and the $r^j_1$’s and the $r^j_2$’s their radii.

4. Solve $\Pi S(\Phi) = 0$. Again consider $\mathcal{J}$ as a functional on $\text{Dom}(\mathcal{J}) \subset \mathcal{Y}$. Let $\Phi \rightarrow \varepsilon_1 \Psi + \varepsilon_2 \Upsilon$ be a two parameter deformation. Then the second variation of $\mathcal{J}$ can be written as

$$\frac{\partial^2}{\partial \varepsilon_1 \partial \varepsilon_2} \mathcal{J}(\Phi + \varepsilon_1 \Psi + \varepsilon_2 \Upsilon) = \langle S'(\Phi)(\Psi), \Upsilon \rangle.$$

Here $S'$ is the Fréchet derivative of $\mathcal{S}$. For each $\Phi \in \text{Dom}(\mathcal{S}) \subset \mathcal{X}$, $S'(\Phi)$ is a linear operator from $\mathcal{X}$ to $\mathcal{Z}$. Then $\langle S'(\Phi)(\Psi), \Upsilon \rangle$ is defined for $\Phi \in \text{Dom}(\mathcal{S}) \subset \mathcal{X}$, $\Psi \in \mathcal{X}$, and $\Upsilon \in \mathcal{Z}$. The left side of (4.1) is also meaningful if $\Phi \in \text{Dom}(\mathcal{J}) \subset \mathcal{Y}$ and $\Psi, \Upsilon \in \mathcal{Y}$.

**Lemma 4.1.**

1. When $\rho$ and $\gamma \rho^3$ are sufficiently small,

$$\|\Pi S'(0)(\Psi)\|_x \geq \frac{1}{2\rho^3} \|\Psi\|_x$$

holds for all $\Psi \in \mathcal{X}_0$. The linear map $\Pi S'(0)$ is one-to-one and onto from $\mathcal{X}_0$ to $\mathcal{Z}_0$ and whose inverse is bounded by $\|\Pi S'(0)^{-1}\| \leq 2\rho^3$.

2. When $\rho$ and $\gamma \rho^3$ are small,

$$\langle \Pi S'(0)(\Psi), \Psi \rangle \geq \frac{1}{2\rho^3} \|\Psi\|^2_\mathcal{Y}$$

for all $\Psi \in \mathcal{Y}_0$.

**Proof.** The operator $S'(0)$ is decomposed into

$$S'(0) = \mathcal{H} + \mathcal{M},$$

where $\mathcal{H}$ is the major part and $\mathcal{M}$ is the minor part. Let

$$\mathcal{H} = (\mathcal{H}^i_1, ..., \mathcal{H}^{n_i}_i, (\mathcal{H}^1_0, \mathcal{H}^1_\pi, \mathcal{H}^1_0), ..., (\mathcal{H}^{n_i}_0, \mathcal{H}^{n_i}_\pi, \mathcal{H}^{n_i}_0)).$$

Then

$$\mathcal{H}^i_1(\Psi) = -\frac{1}{(r^i_\beta)^3} \left( (\psi^i_0)'' + \psi^i_0 \right) - h^i_1(\Psi)$$

$$\mathcal{H}^i_0(\Psi) = -\frac{1}{(r^i_\beta)^3} (\psi^i_0)'(0)$$

$$\mathcal{H}^i_\pi(\Psi) = \frac{1}{(r^i_\beta)^3} (\psi^i_0)'(\pi)$$

(4.6) (4.7) (4.8)
\[ \mathcal{H}_j^i(\Psi) = -\frac{1}{(r_j^i)^3} \left( (\psi_j^i)^{\prime\prime} + \psi_j^i \right) - h_j^i(\Psi) \] (4.9)

where the \( h_j^i(\Psi) \)'s are numbers chosen such that

\[ \int_0^{2\pi} \mathcal{H}_i^i(\Psi) = 0, \quad j = 1, ..., n_i, \quad \int_0^\pi \mathcal{H}_b^j(\Psi) = 0, \quad j = 1, ..., n_b. \] (4.10)

The operator \( \mathcal{H} \) has a non-trivial kernel which is the direct sum of

\[ E_j^i, 1 = \{ \Psi : \psi_j^i = A_1 \cos \theta + A_2 \sin \theta, \ A_1, A_2 \in \mathbb{R}, \ \text{other components of } \Psi \ \text{are 0} \}, \] (4.11)

\[ E_j^b, 0 = \{ \Psi : (\psi_j^0, \psi_j^\pi, \psi_j^b) = B(1, -1, \cos \theta), \ B \in \mathbb{R}, \ \text{other components of } \Psi \ \text{are 0} \}. \] (4.12)

In other words 0 is an eigenvalue of \( \mathcal{H} \) and the associated eigenspace is the direct sum of the \( E_j^i, 1 \)'s and the \( E_j^b, 0 \)'s. Denote this eigenvalue of multiplicity \( n_i + n_b \) by

\[ \lambda_j^i, 1 = 0, \quad j = 1, ..., n_i, \quad \lambda_j^b, 0 = 0, \quad j = 1, ..., n_b. \] (4.13)

The other eigenspaces of \( \mathcal{H} \) are

\[ E_j^i, m = \{ \Psi : \psi_j^i = A_1 \cos m\theta + A_2 \sin m\theta, \ A_1, A_2 \in \mathbb{R}, \ \text{other components of } \Psi \ \text{are 0} \}, \quad m \geq 2 \] (4.14)

\[ E_j^b, m = \{ \Psi : (\psi_j^0, \psi_j^\pi, \psi_j^b) = B(\varphi_m(0), \varphi_m(\pi), \varphi_m), \ B \in \mathbb{R}, \ \text{other components of } \Psi \ \text{are 0} \}, \quad m \geq 1. \] (4.15)

In (4.15), the functions \( \varphi_m \) are

\[ \varphi_m = \begin{cases} \cos \mu_m \left( \theta - \frac{\pi}{2} \right) - \frac{2 \sin \frac{\pi \mu_m}{2}}{\pi \mu_m} & \text{if } m \geq 1 \text{ is odd} \\ \sin \mu_m \left( \theta - \frac{\pi}{2} \right) & \text{if } m \geq 1 \text{ is even} \end{cases}. \] (4.16)

The \( \mu_m \)'s in (4.16) are given as follows. Consider two algebraic equations

\[ \frac{\pi \mu (\mu^2 - 1)}{2(\mu^2 - 1) - \pi \mu^2} = \tan \frac{\pi \mu}{2} \] (4.17)

\[ \frac{\mu}{\mu^2 - 1} = \tan \frac{\pi \mu}{2} \] (4.18)

both considered for \( \mu > 1 \). The solutions to (4.17) are denoted \( \mu_1, \mu_3, \mu_5, ... \), and the solutions to (4.18) are denoted \( \mu_2, \mu_4, \mu_6, ... \). Moreover

\[ 1 < \mu_1 < 2 < \mu_2 < 3 < \mu_3 < 4 < \mu_4 < ... < 2k - 1 < \mu_{2k - 1} < 2k - 2k < 2k + 1 ... \] (4.19)

and

\[ \lim_{k \to \infty} (\mu_{2k - 1} - (2k - 1)) = 0, \quad \lim_{k \to \infty} (\mu_{2k} - 2k) = 0. \] (4.20)

The eigenvalue of \( \mathcal{H} \) associated to \( E_j^i, m \) is clearly

\[ \lambda_j^i, m = \frac{m^2 - 1}{(r_j^i)^3}. \] (4.21)
It is shown in [9, Lemma 3.1] that the eigenvalue associated to $E_{b,m}^j$ is

$$\lambda_{b,m}^j = \frac{\mu_{m}^2 - 1}{(r_b^j)^3}. \quad (4.22)$$

The space $Z_s$ is exactly the subspace of $Z$ that is perpendicular to all the kernel of $\mathcal{H}$, i.e., perpendicular to all $E_{i,1}^j$, $j = 1, \ldots, n_i$, and $E_{b,0}^j$, $j = 1, \ldots, n_b$. It can be written as a direct sum:

$$Z_s = (\oplus_{j=1}^{n_i} \oplus_{m=2}^{\infty} E_{i,m}^j) \oplus (\oplus_{j=1}^{n_b} \oplus_{m=1}^{\infty} E_{b,m}^j). \quad (4.23)$$

The operator $\Pi \mathcal{H}$ restricted to $\mathcal{X}_s$ maps from $\mathcal{X}_s$ to $Z_s$; it is identical to $\mathcal{H}$ restricted to $\mathcal{X}_s$. Moreover in expression $(4.6)$ and $(4.9)$ $h^j_b(\Psi) = 0$ when $\Psi \in \mathcal{X}_s$. The eigenvalues of $\Pi \mathcal{H}$,

$$\lambda_{i,m}^j, \ j = 1, 2, \ldots, n_i, \ m = 2, 3, 4, \ldots, \ \lambda_{b,m}^j, \ j = 1, 2, \ldots, n_b, \ m = 1, 2, 3, \ldots, \quad (4.24)$$

are all positive. Let us denote a pair of orthonormal eigenfunctions associated to the eigenspace $E_{i,m}^j$ by $e_{i,m,1}^j$ and $e_{i,m,2}^j$ and a normalized eigenfunction associated to $E_{b,m}^j$ by $e_{b,m}^j$. For any $\Psi \in Z_s$, one can expand

$$\Psi = \sum_{j=1}^{n_i} \sum_{m=2}^{\infty} \sum_{p=1}^{2} C_{i,m,p}^j e_{i,m,p}^j + \sum_{j=1}^{n_b} \sum_{m=1}^{\infty} C_{b,m}^j e_{b,m}^j. \quad (4.25)$$

The norms in $Z_s$, $\mathcal{Y}_s$ and $\mathcal{X}_s$ are taken to be

$$\|\Psi\|_Z^2 = \sum_{j=1}^{n_i} \sum_{m=2}^{\infty} \sum_{p=1}^{2} |C_{i,m,p}^j|^2 + \sum_{j=1}^{n_b} \sum_{m=1}^{\infty} |C_{b,m}^j|^2, \quad \text{if } \Psi \in Z_s, \quad (4.26)$$

$$\|\Psi\|_Y^2 = \sum_{j=1}^{n_i} \sum_{m=2}^{\infty} \sum_{p=1}^{2} |C_{i,m,p}^j|^2 (m^2 - 1) + \sum_{j=1}^{n_b} \sum_{m=1}^{\infty} |C_{b,m}^j|^2 (\mu_{m}^2 - 1), \quad \text{if } \Psi \in \mathcal{Y}_s, \quad (4.27)$$

$$\|\Psi\|_X^2 = \sum_{j=1}^{n_i} \sum_{m=2}^{\infty} \sum_{p=1}^{2} |C_{i,m,p}^j|^2 (m^2 - 1)^2 + \sum_{j=1}^{n_b} \sum_{m=1}^{\infty} |C_{b,m}^j|^2 (\mu_{m}^2 - 1)^2, \quad \text{if } \Psi \in \mathcal{X}_s. \quad (4.28)$$

It is shown in [9, Lemma 3.2] that the $\| \cdot \|_Y$ norm is equivalent to the usual $H^1$ norm of a Sobolev space and the $\| \cdot \|_X$ norm is equivalent to the $H^2$ norm.

Since for $\Psi \in \mathcal{Y}_s$,

$$\langle \Pi \mathcal{H} \Psi, \Psi \rangle = \sum_{j=1}^{n_i} \sum_{m=2}^{\infty} \sum_{p=1}^{2} |C_{i,m,p}^j|^2 \lambda_{i,m}^j + \sum_{j=1}^{n_b} \sum_{m=1}^{\infty} |C_{b,m}^j|^2 \lambda_{b,m}^j. \quad (4.29)$$

we deduce from (4.27) and (4.28) that

$$\|\Pi \mathcal{H} \Psi\|_Z \geq \frac{1}{1.5 \rho^2} \|\Psi\|_X, \ \forall \Psi \in \mathcal{X}_s, \quad (4.30)$$

$$\langle \Pi \mathcal{H} \Psi, \Psi \rangle \geq \frac{1}{1.5 \rho^2} \|\Psi\|_Y^2, \ \forall \Psi \in \mathcal{Y}_s, \quad (4.31)$$

if $\beta$ in (2.2) is so small that $r_i^j$ and $r_b^j$ are sufficiently close to $\rho$. 
Regarding the minor part $\mathcal{M}$, one has
\[
\|\mathcal{M}(\Psi)\|_Z \leq C \left(\frac{1}{\rho^2} + \gamma\right) \|\Psi\|_X \quad (4.32)
\]
\[
|\langle \mathcal{M}(\Psi), \Psi \rangle| \leq C \left(\frac{1}{\rho^2} + \gamma\right) \|\Psi\|_Y^2. \quad (4.33)
\]

The details of these estimates are found in the proofs of [11, Lemma 5.2] and [9, Lemma 5.1]. Then (4.2) follows from (4.30) and (4.32), and (4.3) follows from (4.31) and (4.33).

Finally to show that $\Pi S'(0)$ is from $X_\delta$ onto $Z_\delta$, note that $\Pi S'(0)$ is an unbounded self-adjoint operator on $Z_\delta$ with the domain $X_\delta \subset Z_\delta$. If $Y \in Z_\delta$ is perpendicular to the range of $\Pi S'(0)$, i.e. $\langle \Pi S'(0)(\Psi), Y \rangle = 0$ for all $\Psi \in X_\delta$, then the self-adjointness of $\Pi S'(0)$ implies that $Y \in X_\delta$ and $\Pi S'(0)(Y) = 0$. By the estimate in part 1, $Y = 0$. Hence, the range of $\Pi S'(0)$ is dense in $Z_\delta$. The estimate in part 1 also implies that the range of $\Pi S'(0)$ is a closed subspace of $Z_\delta$. Therefore $\Pi S'(0)$ is onto. \hfill \square

**Lemma 4.2.** When $\rho$ and $\gamma \rho^3$ are sufficiently small, for each $\xi \in \Xi_\alpha$ and $r \in W_\beta$, the equation $\Pi S(\Phi) = 0$ admits a solution $\Phi_* \in \text{Dom}(S) \cap X_\delta$ satisfying $\|\Phi_*\|_X = O(\rho^3)$.

The proof of this lemma uses a fixed point argument. It makes use of Lemmas 3.5 and 4.1. See the proof of [9, Lemma 6.1] for more details.

The first part of the next lemma shows that $\Phi_*$ is non-degenerate; the second part asserts that $\Phi_*$ is locally energy minimizing among assemblies of perturbed discs and half discs of prescribed centers and radii. The proof of the lemma is the same as the one of [9, Lemma 6.2].

**Lemma 4.3.** 1. For all $\Psi \in X_\delta$
\[
\|\Pi S'(\Phi_*)(\Psi)\|_Z \geq \frac{1}{4 \rho^2} \|\Psi\|_X.
\]

2. For all $\Psi \in Y_\delta$
\[
\langle \Pi S'(\Phi_*)(\Psi), \Psi \rangle \geq \frac{1}{4 \rho^2} \|\Psi\|_Y^2.
\]

The energy of $\Phi_*$ turns out to be very close to the energy of the approximate assembly $E$, as stated in the following lemma. The proof is similar to that of [9, Lemma 6.3].

**Lemma 4.4.** It holds uniformly with respect to $\xi \in \Xi_\alpha$ and $r \in W_\beta$ that
\[
\mathcal{J}(\Phi_*) = \sum_{j \leq n_1} 2\pi r_j^4 + \sum_{j \leq n_b} \pi r_b^4
\]
\[
+ \frac{\gamma}{2} \left[ \sum_{j \leq n_1} \left( \frac{\pi (r_j^4)}{8} \log \frac{1}{r_j^4} + \frac{\pi (r_j^4)}{2} \right) + \left( \frac{\pi (r_j^4)}{8} \right)^2 R(\xi_j, \xi_j') \right]
\]
\[
+ \sum_{j \leq n_b} \left( \frac{\pi (r_j^4)}{4} \log \frac{1}{r_b^4} + \frac{\pi (r_j^4)}{16} \right) + \left( \frac{\pi (r_b^4)}{2} \right)^2 R_b(\xi_b, \xi_b') \right)
\]
\[
+ 2 \sum_{j < k \leq n_1} \pi^2 r_j^2 r_k^2 G(\xi_j, \xi_k) + 2 \sum_{j < k \leq n_b} \left( \frac{\pi (r_b^4)}{2} \right)^2 G(\xi_b, \xi_b')
\]
\[ n_i + \frac{n_b}{2} \quad n_i \quad n_b \quad \text{Minimum } F \]

Table 1. Stationary assemblies with \( n_i + \frac{n_b}{2} \) less than or equal to 4.

\[ + 2 \sum_{j \leq n_i, k \leq n_b} \pi (r_j^i)^2 \left( \frac{\pi (r_k^b)^2}{2} \right) G(\xi_j, \xi_k) \right] + O(\rho^2). \]

5. **Find the right \( \xi \) and \( r \).** Now we emphasize that \( \Phi^* \), the solution of \( \Pi S(\Phi^*) = 0 \) found in Lemma 4.2, depends on \( \xi \) and \( r \), and we denote it by \( \Phi^*(\xi, r) \). The energy of \( \Phi^*(\xi, r) \) can be viewed as a function of \( \xi \) and \( r \), and thus denoted by \( J(\xi, r) \):

\[ J(\xi, r) = J(\Phi^*(\xi, r)), \quad (\xi, r) \in \Xi_\alpha \times W_\beta. \] (5.1)

This function is estimated in Lemma 4.4.

**Lemma 5.1.**

1. Let \( r \in W_\beta \) be fixed. If \( \xi^*_* \) is a critical point of the function \( \xi \to J(\xi, r) \) from \( \Xi_\alpha \) to \( \mathbb{R} \), then \( S(\Phi^*_*(\xi^*_*, r)) = 0 \).
2. If \( (\xi^*_*, r^*_*) \) is a critical point of the function \( (\xi, r) \to J(\xi, r) \) from \( \Xi_\alpha \times W_\beta \) to \( \mathbb{R} \), then \( \Phi^*_*(\xi^*_*, r^*_*) \) is a stationary assembly of \( J \).

**Proof.** Denote the parametrization of the boundary of the perturbed discs in \( \Phi^*_*(\xi, r) \) by \( R^1_1, R^2_2, \ldots, R^n_n \), where

\[ R^i_j(\theta) = \xi^i_j + \sqrt{(r^i_j)^2 + 2\phi^i_j(\theta) e^{i\theta}}. \] (5.2)

The unit tangent and normal vectors of \( R^i_j \) are

\[ T^i_j(\theta) = \frac{\partial R^i_j(\theta)}{\partial \theta}, \quad N^i_j(\theta) = i T^i_j(\theta). \] (5.3)
respectively. Note that $N^b_j(\theta, \beta, \xi)$ is inward pointing.

For the perturbed half discs in $\Phi_*$, denote by $R^i_j(\theta)$, $T^i_j(\theta)$, and $N^i_j(\theta)$, $j = 1, ..., n_b$, the parametrization of the boundary, the unit tangent vector, and the unit normal vector respectively. The corresponding quantities under the $(t(\xi^i_j), n(\xi^i_j))$ frame are $\bar{R}^i_j(\theta)$, $\bar{T}^i_j(\theta)$, and $\bar{N}^i_j(\theta)$. Let us denote the rotation matrix

$$M(\xi^i_j) = (t(\xi^i_j), n(\xi^i_j)).$$

Then

$$R^i_j(\theta) = r(\xi^i_j) + M(\xi^i_j)\bar{R}^i_j(\theta)$$

where

$$\bar{R}^i_j(\theta) = \left(\sqrt{(r^i_j)^2 + 2\phi^{i,b}_j(\theta)\cos \theta}, \sqrt{(r^i_j)^2 + 2\phi^{i,b}_j(\theta)\cos \theta} + f(\sqrt{(r^i_j)^2 + 2\phi^{i,b}_j(\theta)\cos \theta})\right).$$

Fix $r$ and vary each $\xi^i_j$, $k = 1, ..., n_i$, $q = 1, 2$. This leads to a deformation of $\Phi_*$ and a variation along the path

$$\frac{\partial J(\xi, r)}{\partial \xi^{k,q}} = -\sum_{j \leq n_i} \int_{\partial \Omega^i_j} (S^i_j(\Phi_*) + \lambda^i_j(\Phi_*))N^i_j \cdot X^i_j(k, q) \, ds$$

$$+ \sum_{j \leq n_b} \left(\int_{\partial \Omega_j^i} (S^j_0(\Phi_*)X^j_0(k, q) + S^j_0(\Phi_*)X^j_2(k, q) - \int_{\partial \Omega_j^i} (S^j_0(\Phi_*) + \lambda^j_0(\Phi_*))N^j_0 \cdot X^j_2(k, q) \, ds\right)$$

by (3.33). Here $X(k, q)$ is the infinitesimal element of the deformation:

$$X^i_j(k, q) = \frac{\partial R^i_j}{\partial \xi^{k,q}}$$

and $X^0_i(k, q)$ and $X^2_i(k, q)$ are given by (3.31) and (3.32) respectively. Similarly one varies each $\xi^b_j$ to obtain

$$\frac{\partial J(\xi, r)}{\partial \xi^{b,k}} = -\sum_{j \leq n_i} \int_{\partial \Omega^i_j} (S^i_j(\Phi_*) + \lambda^i_j(\Phi_*))N^i_j \cdot X^i_j(k) \, ds$$

$$+ \sum_{j \leq n_b} \left(\int_{\partial \Omega_j^i} (S^j_0(\Phi_*)X^j_0(k) + S^j_0(\Phi_*)X^j_2(k) - \int_{\partial \Omega_j^i} (S^j_0(\Phi_*) + \lambda^j_0(\Phi_*))N^j_0 \cdot X^j_2(k) \, ds\right)$$

where $X(k)$ is the infinitesimal element of the deformation:

$$X^i_j(k) = \frac{\partial R^i_j}{\partial \xi^{b,k}}.$$
Since the deformations $\mathbf{X}(k, q)$ and $\mathbf{X}(k)$ preserve the area of each component,
\begin{align}
\int_{\partial \Omega_i^r} \mathbf{N}_i^j \cdot \mathbf{X}_i^j (k, q) \, ds &= 0, \quad j = 1, \ldots, n_i \\
\int_{\partial \Omega_b^r} \mathbf{N}_b^j \cdot \mathbf{X}_b^j (k, q) \, ds &= 0, \quad j = 1, \ldots, n_b \\
\int_{\partial \Omega_i^l} \mathbf{N}_i^j \cdot \mathbf{X}_i^j (k) \, ds &= 0, \quad j = 1, \ldots, n_i \\
\int_{\partial \Omega_b^l} \mathbf{N}_b^j \cdot \mathbf{X}_b^j (k) \, ds &= 0, \quad j = 1, \ldots, n_b.
\end{align}

One can drop the $\lambda_i^j(\Phi_*)$ terms in (5.7) and (5.9) and arrive at
\begin{align}
\frac{\partial J(\xi, r)}{\partial \xi_{i,q}^k} &= - \sum_{j \leq n_i} \int_0^{2\pi} (A_i^j \cos \theta + A_i^j \sin \theta) \mathbf{N}_i^j \cdot \mathbf{X}_i^j (k, q) \, d\theta \\
&\quad + \sum_{j \leq n_b} \left( B_j^i X_j^i (k, q) - B_j^i X_j^i (k, q) - \int_0^{2\pi} B_j^i \cos \theta \mathbf{N}_b^j \cdot \mathbf{X}_b^j (k, q) \, d\theta \right) \\
\frac{\partial J(\xi, r)}{\partial \xi_{b}^k} &= - \sum_{j \leq n_i} \int_0^{2\pi} (A_i^j \cos \theta + A_i^j \sin \theta) \mathbf{N}_i^j \cdot \mathbf{X}_i^j (k) \, d\theta \\
&\quad + \sum_{j \leq n_b} \left( B_j^i X_j^i (k) - B_j^i X_j^i (k) - \int_0^{2\pi} B_j^i \cos \theta \mathbf{N}_b^j \cdot \mathbf{X}_b^j (k) \, d\theta \right)
\end{align}

At a critical point $\xi_*$ of $\xi \to J(\xi, r)$, the left sides of (5.19) and (5.20) vanish and one obtains a linear homogeneous system for $A_p^j$ and $B_j^i$. One can show, as in the proof of [9, Lemma 8.1], that this system is non-singular and hence
\begin{align}
A_p^j(\xi_*, r) &= 0, \quad j = 1, \ldots, n_i, \quad p = 1, 2, \quad B_j^i(\xi_*, r) = 0, \quad j = 1, \ldots, n_b
\end{align}

proving the first part of the lemma.

For the second part of the lemma, we replace $r$ by a more convenient variable $m$:
\begin{align}
m_i^j = \pi(r_i^j)^2, \quad m_b^j = \pi(r_b^j)^2
\end{align}

One varies each $m_b^j$ to obtain another deformation of $\Phi_*$. Since $A_p^j(\xi_*, m_*) = 0$ and $B_j^i(\xi_*, m_*) = 0$, the first variation formula (3.33) yields
\begin{align}
\left. \frac{\partial J(\xi, m)}{\partial m^k \nu} \right|_{(\xi, m) = (\xi_*, m_*)} &= - \sum_{j \leq n_i} \int_{\partial \Omega_i^r} \lambda_i^j(\xi_*, m_*) \mathbf{N}_i^j \cdot \mathbf{X}_i^j (\nu, k) \, ds \\
&\quad - \sum_{j \leq n_b} \int_{\partial \Omega_b^r} \lambda_b^j(\xi_*, m_*) \mathbf{N}_b^j \cdot \mathbf{X}_b^j (\nu, k) \, ds \\
&\quad = - \sum_{j \leq n_i} \lambda_i^j(\xi_*, m_*) \frac{\partial \Omega_i^j}{\partial m^k \nu} - \sum_{j \leq n_b} \lambda_b^j(\xi_*, m_*) \frac{\partial \Omega_b^j}{\partial m^k \nu} \\
&\quad = - \sum_{j \leq n_i} \lambda_i^j(\xi_*, m_*) \frac{\partial m_i^j}{\partial m^k \nu} - \sum_{j \leq n_b} \lambda_b^j(\xi_*, m_*) \frac{\partial m_b^j}{\partial m^k \nu}
\end{align}
there exists a Lagrange multiplier 

Here $X$ is the infinitesimal element of the deformation. Note that the area of the component $\Omega_p$ is not preserved in this deformation. Because $m_p^i$ are constrained by

$$
\sum_{j \leq n_i} m_i^j + \sum_{j \leq n_b} \frac{m_b^j}{2} = \omega |D|,
$$

there exists a Lagrange multiplier $\lambda \in \mathbb{R}$ such that

$$
\frac{\partial J(\xi, m)}{\partial m_k^i} \bigg|_{(\xi, m) = (\xi, m_s)} + \lambda = 0, \quad \frac{\partial J(\xi, m)}{\partial m_b^j} \bigg|_{(\xi, m) = (\xi, m_s)} + \frac{\lambda}{2} = 0.
$$

It follows from (5.23) and (5.25) that

$$
\lambda_k^b(\xi_s, m_s) = \lambda, \quad k = 1, \ldots, n_P, \quad \nu = i, b.
$$

This proves the second part of the lemma.

**Proof of Theorem 1.1.** Consider $J$ in the domain $\Xi_\alpha \times W_\beta$ where $\Xi_\alpha$ and $W_\beta$ are given in (2.1) and (2.2) respectively. One views $\Xi_\alpha$ as a compact $2n_i + n_b$ dimensional manifold with boundary and $W_\beta$ as a compact $n_i + n_b - 1$ dimensional manifold with boundary. Then $\Xi_\alpha \times W_\beta$ is a compact $3n_i + 2n_b - 1$ dimensional manifold with boundary. For each $(\xi, r) \in \Xi_\alpha \times W_\beta$ there is $\Phi_\ast(\xi, r)$ that solves $\Pi S(\Phi_\ast(\xi, r)) = 0$ by Lemma 4.2. Since $\Xi_\alpha \times W_\beta$ is compact, there exists $(\xi_s, r_s) \in \Xi_\alpha \times W_\beta$ that minimizes $J$ in $\Xi_\alpha \times W_\beta$. It suffices to show that $(\xi_s, r_s)$ is in the interior of $\Xi_\alpha \times W_\beta$.

First prove

$$
\frac{r_s^j}{\rho} \rightarrow 1 \text{ and } \frac{r_s^j}{\rho} \rightarrow 1, \text{ as } \rho \rightarrow 0.
$$

Let $R_i^j = \frac{r_i^j}{\rho}$ and $R_b^j = \frac{r_b^j}{\rho}$, so $R = (R_i^1, \ldots, R_i^{n_i}, R_b^1, \ldots, R_b^{n_b})$ is a scaled version of $r$. By Lemma 4.4 we write

$$
J(\xi, r) = J(\xi, R) = \left( \gamma \rho^4 \log \frac{1}{\rho} \right) J_1(R) + \gamma \rho^4 J_2(\xi, R) + O(\rho^2)
$$

where

$$
J_1(R) = \frac{1}{\gamma \rho^3 \log \frac{1}{\rho}} \left( \sum_{j \leq n_i} 2\pi R_i^j + \sum_{j \leq n_b} \pi R_b^j \right)
+ \frac{1}{2} \left[ \sum_{j \leq n_i} \frac{\pi(R_i^j)^4}{4} + \sum_{j \leq n_b} \frac{\pi(R_b^j)^4}{4} \right]
$$

$$
J_2(\xi, R) = \frac{1}{2} \left[ \sum_{j \leq n_i} \left( \frac{\pi(R_i^j)^4}{2} \log \frac{1}{R_i^j} + \frac{\pi(R_i^j)^4}{8} + \left( \frac{\pi(R_i^j)^2}{2} \right)^2 R_i(\xi_i^j, \xi_i^j) \right) \right]
+ \sum_{j \leq n_b} \left( \frac{\pi(R_b^j)^4}{4} \log \frac{1}{R_b^j} + \frac{\pi(R_b^j)^4}{16} + \left( \frac{\pi(R_b^j)^2}{2} \right)^2 R_b(\xi_b^j, \xi_b^j) \right).
$$
\[ +2 \sum_{j<k \leq n_i} \pi^2(R_j^i)^2(R_k^i)^2G(\xi_j^i, \xi_k^i) \]
\[ +2 \sum_{j<k \leq n_b} \left( \frac{\pi(R_j^b)^2}{2} \right) \left( \frac{\pi(R_k^b)^2}{2} \right)G(\xi_j^b, \xi_k^b) \]
\[ +2 \sum_{j \leq n_i, k \leq n_b} \pi(R_j^i)^2 \left( \frac{\pi(R_k^b)^2}{2} \right)G(\xi_j^i, \xi_k^b) \].
\[ (5.30) \]

Because of the lower bound \( \frac{1}{\rho^3 \log \frac{1}{\rho^3}} < \gamma \) for \( \gamma \) in this theorem, the term \( O(\rho^3) \) in (5.28) is much smaller than the other two terms in (5.28). By (2.4), the condition \( \frac{1}{\gamma \rho^3 \log \frac{1}{\rho^3}} < \frac{1}{1+\beta} \) in the theorem, the range \( R_i^j, R_b^j \in [1-\beta, 1+\beta] \), and the constraint
\[ \sum_{j \in N_i} (R_j^i)^2 + \sum_{j \in N_b} (R_j^b)^2 = n_i + \frac{n_b}{2}, \]
(5.31)
one derives that \( J_1 \) is minimized at \( R_i^j = R_b^j = 1 \). The corresponding \( r_i^j = r_b^j = \rho \) is a point in the interior of \( W_\beta \). Since (5.28) implies that
\[ \frac{1}{\gamma \rho^4 \log \frac{1}{\rho^4}} J(\xi, R) \to J_1(R), \text{ as } \rho \to 0, \]
(5.32)
uniformly with respect to \( \xi \) and \( R, R_* = \frac{\tau_\rho}{\rho} \) must converge to the minimum of \( J_1 \), i.e.
\[ R_* \to (1, \ldots, 1, 1, \ldots, 1) \text{ as } \rho \to 0, \]
(5.33)
so (5.27) follows. Next consider \( J(\xi, r_*) \) where \( \xi \in \Xi_\alpha \) but \( r \) is taken to be \( r_* \) and correspondingly \( R = R_* \). By (5.28) and (5.33),
\[ \lim_{\rho \to 0} \frac{1}{\gamma \rho^4} \left( J(\xi, R) - \left( \gamma \rho^4 \log \frac{1}{\rho} \right) J_1(R_*) \right) = \lim_{\rho \to 0} J_2(\xi, R_*) \]
\[ = \frac{1}{2} \left( \frac{n_i \pi}{8} + \frac{n_b \pi}{16} + \pi^2 F(\xi) \right) \]
(5.34)
uniformly with respect to \( \xi \). Consequently, since \( J_1 \) does not depend on \( \xi \), every limit point of \( \xi_* \) along a subsequence must be a minimum of \( F \) in \( \Xi_\alpha \). But (2.3) says that a minimum of \( F \) in \( \Xi_\alpha \) is also a minimum of \( F \) in \( \Xi \) and it is not on the boundary of \( \Xi_\alpha \).

The last assertion and (5.27) imply that when \( \rho \) is small, \( (\xi_*, r_*) \) is in the interior of \( \Xi_\alpha \times W_\beta \). Therefore \( (\xi_*, r_*) \) is a critical point of \( J \), and the theorem follows from Lemma 5.1.2. \( \square \)

**Proof of Theorem 1.2.** The first part is proved in (5.27) and the second part is proved after (5.34). Our assertion that \( \Phi_\alpha(\xi_*, r_*) \) is a stable assembly is based on the fact that this stationary point is obtained in successive (local) minimization procedures. In section 4 for each \((\xi, r)\) in \( \Xi_\alpha \times W_\beta \), \( \Phi_\alpha(\xi, r) \) was found as a fixed point. Because of Lemma 4.3.2, \( \Phi_\alpha(\xi, r) \) is locally minimizing in \( \mathcal{X}_\alpha \), i.e. locally minimizing in the class of assemblies whose discs are centered at \( \xi_\mu^i \) and of radii \( r_\mu^j \). Then in the proof of Theorem 1.1, \((\xi_*, r_*)\) is taken to be the minimum of \( J(\Phi_\alpha(\xi, r)) \) with respect to \((\xi, r)\) in \( \Xi_\alpha \times W_\beta \). \( \square \)
Table 2. Stationary assemblies with $n_i + \frac{n_b}{2} = 10$.  

| $n_i + \frac{n_b}{2}$ | $n_i$ | $n_b$ | $\text{Minimum } F$ |
|------------------------|------|------|---------------------|
| 10                     | 10   | 0    | -2.5781             |
| 10                     | 9    | 2    | -2.5819             |
| 10                     | 8    | 4    | **-2.5885**         |
| 10                     | 7    | 6    | -2.5793             |
| 10                     | 6    | 8    | -2.5644             |
| 10                     | 5    | 10   | -2.5433             |
| 10                     | 4    | 12   | -2.4791             |
| 10                     | 3    | 14   | -2.2864             |
| 10                     | 2    | 16   | -1.9222             |
| 10                     | 1    | 18   | -1.3549             |
| 10                     | 0    | 20   | -0.3911             |

6. **Boundary half discs lower energy.** Let $\Phi_*(\xi^*, r_*)$ be an stationary assembly found in Theorem 1.1. Since the $r_{j,i}$ and $r_{j,b}$ are all close to $\rho$ according to Theorem 1.2, by Lemma 4.4 $\mathcal{J}(\Omega_*)$ is approximately equal to

$$\mathcal{J}(\Omega_*) \approx 2\pi \left( n_i + \frac{n_b}{2} \right) \rho + \frac{\pi \gamma \rho^4 \log \frac{1}{\rho} \left( n_i + \frac{n_b}{2} \right)}{4} + \frac{\pi \gamma \rho^4 \left( n_i + \frac{n_b}{2} \right)}{16} + \frac{\pi^2 \gamma \rho^4 F(\xi_*)}{2}.$$  

Assume that $\gamma$ and $\omega$ are in a specific parameter range such that

$$\gamma = \frac{\mu}{\omega^{3/2} \log \frac{1}{\omega}} = \frac{\mu}{\left( \frac{n_i + \frac{n_b}{2}}{|D|} \right)^{3/2} \rho^3 \log \frac{|D|}{(n_i + \frac{n_b}{2}) \pi \rho^2}}.$$  

for a fixed $\mu > 0$. The leading order of the free energy calculated from (6.1) is

$$2\pi \left( n_i + \frac{n_b}{2} \right) \rho + \frac{\pi \gamma \rho^4 \left( n_i + \frac{n_b}{2} \right) \log \frac{1}{\rho}}{4} = 2\sqrt{\omega |D| \pi} \sqrt{n_i + \frac{n_b}{2}}$$

$$+ \sqrt{\omega |D|^2 \mu \frac{1}{8\pi}} \frac{1}{n_i + \frac{n_b}{2}} + \text{smaller term.}$$  

With respect to $n_i + \frac{n_b}{2}$ the last quantity is minimized at

$$n_i + \frac{n_b}{2} \approx \frac{|D| \mu^{2/3}}{4\pi}.$$  

This gives the optimal number of discs in a stationary assembly. Note that under (6.2) and (6.4), the corresponding $\rho$ and $\gamma$ fall into the range specified in Theorem 1.1.

One should compare the energy of stationary assemblies of the same area, i.e. the same $\omega$, and the same number of discs, i.e. the same $n_i + \frac{n_b}{2}$. In particular one can compare stationary assemblies of the same area and of the optimal number of discs. Then all disc radii are approximately equal to the same $\rho$. One must look at the higher order term to distinguish the energy of these assemblies. By (6.1), the
energy in the higher order is determined by $F(\xi_*).$ This leads to the minimization of $F.$

Let the domain $D$ be the unit disc $\{x \in \mathbb{R}^2 : |x| < 1\}$ so that the Green’s function of $-\Delta$ is explicitly known:

$$G(x, y) = \frac{1}{2\pi} \log \frac{1}{|x - y|} + \frac{1}{2\pi} \left( \frac{|x|^2}{2} + \frac{|y|^2}{2} + \log \frac{1}{|x|^2 - 1} \right) - \frac{3}{8\pi}. \quad (6.5)$$

Table 1 lists the numerical minimum value of $F$ together with $n_i + \frac{n_b}{2}$, $n_i$, and $n_b$. A row with highlighted minimum $F$ value is the stationary assembly with the lowest energy among all stationary assemblies of the same $\omega$ and the same $n_i + \frac{n_b}{2}$. For instance, when $n_i + \frac{n_b}{2} = 3$ the stationary assembly with the lowest energy has 2 interior discs and 2 boundary half discs.

One has a more realistic scenario when $n_i + \frac{n_b}{2}$ is a large number. Table 2 lists stationary assemblies with $n_i + \frac{n_b}{2} = 10$. Here the assemblies with 9, 8, 7 interior discs respectively have lower energy than the one with interior discs only. The assembly of the lowest energy has 8 interior discs and 4 boundary half discs.

As one finds the minimum of $F$ numerically, the centers of the interior discs and the boundary half discs of a stationary assembly are determined. Figure 1 shows these stationary assemblies based on the numerical minimum of $F$ for all the cases with $n_i + \frac{n_b}{2} = 10$.
