Exercise-induced coronary artery dissection in a 54-year-old male without atherosclerosis: A case report

Paul Ellis, Victoria Grey, Anthony D’Sa, Derek Connolly

ABSTRACT

Introduction: Spontaneous coronary artery dissection (SCAD) is an unusual cause of chest pain most often presenting in peripartum or postpartum women. The SCAD precipitated by exercise in patients without underlying atherosclerosis is very rare and has been described in literature only on a few occasions. It has never been described in a male above the age of 40.

Case Report: We present the case of a 54-year-old male presented with acute ST elevation myocardial infarction having suffered a left anterior descending artery dissection following an intense gym workout. He was successfully managed with coronary stenting. The patient suffered from on-going chest pain after initial recovery and was investigated with CT coronary angiography to assess stent patency and for evidence of underlying coronary artery disease. This showed a calcium score of 0 and no evidence of underlying atherosclerosis with a patent stent.

Conclusion: In conclusion, SCAD should be considered in the differential diagnosis of patients presenting with acute coronary syndrome, even those without coronary risk factors.

INTRODUCTION

Spontaneous coronary artery dissection is an extremely rare condition that has a variety of presentations including angina, acute coronary syndrome, heart failure, arrhythmias and, in some cases, sudden death [1, 2]. We describe the case of a 54-year-old male with exercise induced coronary artery dissection presenting with acute coronary syndrome with discussion and review of literature.

CASE REPORT

A 54-year-old male who had just finished his first ever gym session with a personal trainer was presented with a two-hour history of central chest pain radiating to his left arm. He had never experienced this chest pain before. The pain settled with the administration of sublingual nitrates and aspirin 300 mg.
The patient denied any significant past medical history and had no personal or family history of ischemic heart disease. He was a non-smoker, exercised regularly and did not use recreational drugs. His baseline serum cholesterol was 5.2 mmol/L with HDL 1.3 mmol/L, and he had been started on simvastatin 40 mg daily recently by his family doctor.

Physical examination was unremarkable including no signs of connective tissue disease.

A 12-lead ECG showed subtle 1 mm ST elevation in V5 and V6. Chest radiograph showed clear lung fields and no cardiomegaly.

Coronary angiography revealed a dissection flap in the proximal left anterior descending artery, TIMI grade II flow (Figure 1). This was subsequently successfully stented with deployment of a Xience Prime 3.5x12 mm post dilated to 4 mm with an NC Trek non-compliant balloon inflated to 16 atmospheres.

Cardiac enzymes were elevated with serial troponins of 16 ng/L on presentation and 54 ng/L four hours later.

The patient was discharged with aspirin 75 mg, perindopril 2 mg, atorvastatin 80 mg daily and ticagrelor 90 mg twice daily.

Three months later, the patient continued to have atypical chest pain and was keen to know whether his myocardial infarction was related to coronary disease. Cardiac computed tomography scan was performed to assess stent patency and the degree of coronary artery atherosclerosis. This demonstrated an Agatston calcium score of 0 and the coronary angiography did not identify any coronary artery disease and demonstrated a patent stent in the left anterior descending artery (Figure 2).

The patient was started on a cardiac rehabilitation program and continues to make good progress six months after the coronary artery dissection.

**DISCUSSION**

This case is unique as it demonstrates a spontaneous left anterior descending artery dissection caused by exercise alone without the presence of atherosclerosis in a middle aged man. It is also the first reported case of utilization of CT coronary angiography to investigate for atherosclerosis in a patient with SCAD.

We reviewed 13 cases of exercise induced coronary artery dissection from 1995 to 2014. Nine of these patients were male and the mean age at the time of dissection was 36 years of age ranging from 17 to 53 years. The risk factors each patient had were analyzed; 30.7% were smokers, 30% had high cholesterol and 15.3% had a family history of ischemic heart disease [1, 3–12]. Obesity was identified as a further risk factor in one of these patients [5]. In addition, one patient was an ex-smoker and had stopped smoking 6 years prior to the dissection [12]. The remaining 6 patients were found to have no risk factors for coronary artery disease or risk factors were not declared. The female to male ratio of these 6 patients was equal [1, 3, 7, 8, 10, 13].

From literature reviewed, seven cases (53.8%) were associated with aerobic activity and five cases (38.4%) were associated with anaerobic activity disease [1, 3–12]. One further case that was found was associated with severe emotional distress and anxiety [3]. Additionally, five patients had delayed presentation after the initial event, the longest delay in presentation being a patient who presented following a cycling tour who had suffered angina pain for four months but had not sought medical attention [9].
The left anterior descending artery was the vessel most commonly affected with eight of the cases in literature review involving this artery alone [3–6, 8, 9, 12]. Three further cases involved only the circumflex artery and finally two cases involved multiple coronary vessels [1, 3, 7, 10, 11].

Spontaneous coronary artery dissection (SCAD) is a rare and unusual cause of acute coronary syndrome with an approximate incidence of between 0.07% and 0.1% of patients having coronary angiography [14, 15]. Since the first described case of spontaneous coronary artery dissection by Pretty et al. [16] in 1931 three main groups of patients with SCAD have been identified [17]:

(i) Peripartum and post partum women.
(ii) Patients with underlying atherosclerosis.
(iii) Idiopathic group without risk factors for coronary artery disease [11].

Women are most commonly affected [17], one study finding that 70% of all cases of SCAD from 1931 to 2008 were men, 26.1% of which were either pregnant or postpartum [18]. It has been postulated that high levels of oestrogen and progesterone with increased levels of collagenases during and after pregnancy may contribute to the development of SCAD in this group of patients [8, 10].

The second group is with underlying atherosclerosis. There is debate as to whether this group has truly had spontaneous coronary artery dissection because of the underlying weakness in the artery wall predisposing them to SCAD [6, 17]. Tweet et al. suggest that plaque dissection may well represent a differing presentation of typical acute coronary syndrome and that non-atherosclerotic SCAD is clinically separate [15].

The third group is that of idiopathic origin in patients without atherosclerosis. This includes those with connective tissue disease; such as Marfans syndrome, cocaine use [19], vasculitis, chest trauma, and as in this case, vigorous exercise [15]. Of the small proportion of cases where exercise is alone believed to be the precipitating event, many have risk factors or are found to have atherosclerosis with coronary angiography [3, 4] and the coronary dissection cannot be considered truly SCAD. We have found only one case that has described exercise induced coronary artery dissection in a patient without atherosclerosis demonstrated with CT coronary angiography in a 25-year-old male [7].

The pathogenesis of SCAD is still poorly understood due to its rarity. Alfonso et al. has identified two pathological subsets of patients [20]. The first are those with an intimal tear where the true and false lumens communicate directly. Initial intimal disruption may be due to a number of factors including structural changes in the vessel wall, increased shearing stress from hyperdynamic circulation or physical exertion [5]. Patients of second group are those who presented without an intimal tear. It has been suggested that this group may have a primary abnormality in the vasa vasorum [20]. In both subsets of patients, on-going hemorrhage or expanding hematoma within the false lumen compromises the true coronary lumen which manifests in myocardial ischemia and the presentation of acute coronary syndrome [3, 7, 20].

The SCAD usually presents with dissection of a single vessel, the left anterior descending artery being most commonly affected [10]. Management of SCAD depends on a multitude of factors. These include location of dissection, number of coronary vessels involved, patient presentation and patient preference. Many studies agree that surgery with coronary artery bypass grafting is most suitable for involvement of the left main stem or for multiple vessel involvement. Studies where percutaneous coronary intervention has been used mostly involves the stenting of a single vessel [3, 5, 8, 9] including the case described. Medical therapy has also been demonstrated to be an effective treatment option but is often used in stable patients without ongoing ischemia, in cases where extensive dissection is not suitable for intervention or in those that decline surgical or percutaneous intervention [1, 2, 6, 7, 13].

CONCLUSION

In conclusion, spontaneous coronary artery dissection should be considered in the differential diagnosis of young patients or those without risk factors presenting with acute coronary syndrome.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.

Most Favored Author program
Join this program and publish any number of articles free of charge for one to five years.

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

We welcome you to interact with us, share with us, join us and of course publish with us.

CONNECT WITH US

We thank you for your interest and support. We look forward to working with you.
