ABSTRACT: We present two new classes of black string solutions in the context of mimetic gravity. The horizon topology of these solutions can be either a flat $T^2$ torus with topology $S^1 \times S^1$, or a standard cylindrical model with topology $R \times S^1$. The first class describes uncharged rotating black string which its asymptotic behaviour is approximately anti-de Sitter (AdS), while the second class represents asymptotically AdS charged rotating black string. We study the casual structure and physical properties of these spacetimes and calculate the mass and angular momentum per unit length of rotating black strings.
1 Introduction

The idea of the mimetic gravity was proposed [1], in order to shed the light on the problem of dark matter. Roughly speaking, isolating the conformal degree of freedom of the gravitational field in a covariant way, it was shown that the conformal degree of freedom can be dynamical even in the absence of matter. As a result, the extra scalar longitudinal degree of freedom of the gravitation field, can be interpreted as the energy density of the mimetic field which scales in term of the scale factor $a$, as $a^{-3}$, which resembles the contribution of pressureless dust, without needing to particle dark matter [1]. In the past few years, mimetic theory of gravity has arisen a considerable attentions both in the cosmological setup as well as in stationary background. Cosmological dynamics of mimetic gravity, with various form of the potential for the mimetic field, has been investigated [2, 3]. It has been confirmed that this scenario can describe the thermal history of the universe, namely the successive sequence of radiation, matter, and dark-energy eras [3]. Besides, at late times, mimetic cosmology is capable to alleviate the cosmic coincidence problem and can be brought into good agreement with observational data [3]. It has been realized that with modification to the action of mimetic gravity, this model can address the singularities in contracting Friedmann and Kasner universes and yields a universe with limiting curvature and regular bounce [4]. Considering the coupling between mimetic scalar field with a vector field, an anisotropic model of mimetic cosmology was explored in [5]. While inflationary model in the context of mimetic $f(G)$ gravity has been explored [6], a unified description of dark energy and dark matter in the context of mimetic theory was suggested in [7]. Other studies on the mimetic cosmology can be found in [8–17].

Parallel to the mimetic cosmology, the studies on static and stationary solutions of mimetic gravity started and have also being continued. Static and spherically symmetric black hole solutions of mimetic gravity have been explored in [18, 19]. The studies have also been generalized to modified Gauss-Bonnet mimetic gravity [20] as well as $f(R)$ mimetic theory [21–24]. In particular, it has been realized that, by suitably chosen mimetic potential for a given $f(R)$ gravity, this model admits an inflationary cosmology compatible with
Planck observations [21]. It was also observed that by modifying the action of mimetic gravity, a regular black hole can be exist without singularity inside the Schwarzschild spacetime [25]. Topological black holes in mimetic gravity in the presence of constant potential for the mimetic field were recently obtained in [26]. By gluing an exterior static solution to a time-dependent anisotropic interior solution, the authors of [27] constructed mimetic black hole spacetime. They also revealed that these two solutions match continuously on the event horizon [27]. The authors of [28, 29] considered static and rotating solutions of mimetic gravity with flat or cylindrical horizon in the presence of cosmological constant. However, the obtained solution in [28, 29] are indeed nothing but the well-known black brane/string solutions of Einstein gravity. The reason is that they have simply assumed $g_{tt} = -g^{rr}$, and arrived at a special solution of the mimetic field equations. In order to reflect the impact of the extra degree of freedom of the gravitational field equations, encoded in the mimetic scalar field, on the metric functions, one need to consider the more general spacetime with $g_{tt} \neq -g^{rr}$ [18, 19, 26, 27, 30–32]. Other studies on mimetic gravity can be carried out in [33–38].

One of the main question concerning mimetic theory, is that whether this theory is capable to reproduce the inferred flat rotation curves of galaxies. It was shown that adding a non-minimal coupling between matter and mimetic field yields the appearance of an extra force and the resulting equations of motion in the weak field limit provides a Modified Newtonian Dynamics (MOND)-like [39] theory which may alleviate the flat rotation curves of spiral galaxies without needing to particle dark matter. Also, constructing the potential associated with the mimetic field, by applying an inverse approach, for a general static spherically symmetric spacetime, it has been shown that the corrections to the Schwarzschild spacetime could provide an explanation for the inferred flat rotation curves of spiral galaxies within the mimetic gravity framework [19]. More recently, it has been realized [26] that one is capable to reproduce the flat galactic rotation curves, in the context of mimetic gravity, without neither modifying the action [39] nor taking into account a complicated potential for the mimetic field [19]. Indeed, the original theory of mimetic gravity [1] was proposed in such a way that it naturally mimics dark matter as a geometrical effect. It was argued that the origin of the responsible term for recovering the flat galactic rotation curves in a static spacetime, is exactly the one which mimics dark matter in the cosmological setup [26].

In this paper, we are going to construct the general rotating black string solutions in the context of mimetic gravity. The rotating solutions of the Einstein equation with a negative cosmological constant with cylindrical and toroidal horizons have been investigated in [40]. The extension to include the Maxwell field has been done and the static and rotating electrically charged black string have been considered in [41–44]. When the gauge field is in the form of nonlinear electrodynamics, rotating black string solutions have been explored in [45, 46]. The studies on the rotating black strings were also generalized to dilaton gravity [47, 48], holographic superfluids [49] and $f(R)$ gravity [50].

This paper is structured as follows. In Sec. 2, we introduce the action and basic field equations. In Sec. 3, we analyze rotating black string in the context of mimetic gravity. In Sec. 4, we generalize our study to the case of charged rotating mimetic black string. We
2 Field equations

The action of mimetic gravity in the presence of mimetic potential is \[ S = \int d^4x \sqrt{-g} \left[ R + \lambda (\partial \phi \partial \phi - \epsilon) - V(\phi) + \mathcal{L}_m \right], \] (2.1)

where \( R \) is the Ricci scalar curvature, \( \lambda \) is the Lagrange multiplier, and \( V = V(\phi) \) is the potential for the mimetic scalar field \( \phi \). Here \( \mathcal{L}_m = -F_{\mu\nu}F^{\mu\nu} \) is the Lagrangian of the Maxwell field, where \( F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu \) is the electromagnetic field tensor and \( A_\mu \) is the gauge potential. Besides, \( \epsilon = \pm 1 \) depends on the spacelike or timelike nature of the vector field \( \partial_\mu \phi \). \( \epsilon = +1 \) corresponds to spacelike vector field \( \partial_\mu \phi \), while \( \epsilon = -1 \) indicates timelike \( \partial_\mu \phi \). Through this paper we set \( 8\pi G_N = 1 \) and work in the metric signature \((-,+,+,+).\)

From the variation of the above action with respect to \( \lambda \), one immediately finds

\[ \nabla^\mu (\lambda \partial_\mu \phi) = \frac{1}{\epsilon} \frac{dV(\phi)}{d\phi}, \] (2.2)

This constraint imposes strong restriction on the functional form of \( \phi \) which in general depends on the metric line elements of the underlying theory. This condition can also be understood by assuming the physical metric \( g_{\mu\nu} \) to be a function of two variables; namely an auxiliary metric \( \tilde{g}_{\mu\nu} \) plus a scalar field \( \phi \) and redefine the metric as \( g_{\mu\nu} = \epsilon (\tilde{g}^{\alpha\beta} \partial_\alpha \phi \partial_\beta \phi) \tilde{g}_{\mu\nu} \) [1]. Then, one can immediately recovers (2.2). It was argued that considering this non-invertible conformal/disformal transformation, increases the number of degrees of freedom in such a way that in addition to two transverse degrees of freedom describing gravitons, the gravitational field acquires an extra dynamical longitudinal mode [32, 51].

The equations of motion can be derived by varying the action with respect to the metric \( g_{\mu\nu} \), the scalar field \( \phi \), and the gauge field \( A_\mu \). The result is

\[ G_{\mu\nu} = \lambda \partial_\mu \phi \partial_\nu \phi - \frac{1}{2} g_{\mu\nu} V(\phi) + T_{\mu\nu}, \] (2.3)

\[ \nabla^\mu (\lambda \partial_\mu \phi) = - \frac{1}{2} \frac{dV(\phi)}{d\phi}, \] (2.4)

\[ \partial_\mu \left( \sqrt{-g} F^{\mu\nu} \right) = 0, \] (2.5)

where the energy momentum tensor of the Maxwell field is given by

\[ T_{\mu\nu} = 2F_{\mu\gamma}F_{\nu}^{\gamma} - \frac{1}{2} g_{\mu\nu} F^{\alpha\beta} F_{\alpha\beta}, \] (2.6)

Now, we take the trace of Eq. (2.3), combining with Eq. (2.2), yields

\[ \lambda = \epsilon (G - T + 2V), \] (2.7)

where \( G = G^\mu_\mu \) and \( T = T^\mu_\mu \) are, respectively, the trace of the Einstein tensor and energy momentum tensor. Inserting \( \lambda \) in the field Eqs. (2.3) and (2.4), we arrive at

\[ G_{\mu\nu} = \epsilon (G - T + 2V) \partial_\mu \phi \partial_\nu \phi - \frac{1}{2} g_{\mu\nu} V(\phi) + T_{\mu\nu}, \] (2.8)
\[ \nabla^\mu [(G - T + 2V) \partial_\mu \phi] = -\frac{\epsilon}{2} \frac{dV(\phi)}{d\phi}. \]  \hspace{1cm} (2.9)

Our aim here is to construct rotating black string solutions of the above field equations and investigate their properties. The metric of four-dimensional rotating solution with cylindrical or toroidal horizons can be written as \[ (2.10) \]

\[ ds^2 = -f(r)g^2(r)(\Xi dt - ad\varphi)^2 + \frac{dr^2}{f(r)} + \frac{r^2}{l^4} \left(adt - \Xi l^2 d\varphi \right)^2 + \frac{r^2}{l^2} dz^2, \]

where the constants \(a\) and \(l\) have dimensions of length and as we will see later, \(a\) is the rotation parameter and \(l\) can be interpreted as the AdS radius, in case of constant potential. Compared to the line element of the rotating black string of Einstein gravity \[ (2.11) \]

\[ f(r)\phi'^2 = \epsilon, \quad \phi(r) = \pm \int \frac{dr}{\sqrt{\epsilon f(r)}} + \text{const}, \]

where without loss of generality one may choose + sign of integral. The scalar field is always constrained by Eq. (2.2) or, equality in our case, by Eq. (2.11). Therefore, we have no new degrees of freedom for the scalar field \(\phi\). Indeed, this constrained scalar field is not dynamical by itself, but induces mimetic dark matter in Einstein theory making the longitudinal mode of gravity dynamical \[ (2.12) \]

\[ \partial^\mu \phi \epsilon \] depending on the sign of the metric function \(f(r)\). Let us denote the positive real root of equation \(f(r) = 0\) by \(r_+\). Clearly, \(r_+\) is the radius of the event horizon of the black string (indeed \(g_{\theta\theta} = f(r) = 0\) determines the horizon), for which the metric function \(f(r)\) changes sign over it. For outer solution where \(r > r_+\), we have \(f(r) > 0\), while for inner solution \((r < r_+)\), we expect \(f(r) < 0\). Clearly, in case of timelike \(\partial^\mu \phi\) \((\epsilon = -1)\), for outer solution \((f(r) > 0)\), the mimetic field becomes imaginary, while for inner solution \((f(r) < 0)\), \(\phi\) is a real function as well. Clearly, for spacelike \(\partial^\mu \phi\) \((\epsilon = 1)\), the situation exchanges, i.e., \(\phi\) is real for outer solution \((f(r) > 0)\), and becomes imaginary for inner solution \((f(r) < 0)\). Let us remind that in the cosmological setup the vector field \(\partial^\mu \phi\) is always timelike because it

\[ -4 - \]
plays the role of the four-velocity $u^\mu$ of the perfect fluid, where $\phi$ is the velocity potential [1]. Indeed, in the background of Friedmann-Robertson-Walker universe the general solution of the constraint equation (2.2) is $\phi = \pm t + A$, where $A$ is an integration constant, and without loss of generality one can identify $\phi = t$ [2]. However, in the context of black hole/string, where, by definition, the spacetime has an event horizon, the vector field $\partial_r \phi$ changes from a spacelike vector to a timelike vector over the horizon. However, since, the scalar field $\phi$ is not dynamical by itself, one may not worry about this behaviour and can still search for black hole/string solutions with real $f(r)$.

Considering the metric (2.10), the gauge potential takes the form

$$A_\mu = h(r) \left( \Xi \delta^0_\mu - a \delta^\phi_\mu \right).$$  \hfill (2.12)

With this gauge potential at hand, the nonvanishing components of the electromagnetic tensor become

$$F_{tr} = \Xi h'(r), \quad F_{\varphi r} = -ah'(r) = -\frac{a}{\Xi} F_{tr}. $$  \hfill (2.13)

Inserting the gauge potential (2.12) into Eq. (2.5), one finds that the non-vanishing components of the Maxwell equation are just the $(t)$ and $(\varphi)$ components, which both of them yield the following equation

$$rh''(r)g(r) - rh'(r)g'(r) + 2h'(r)g(r) = 0, \quad (2.14)$$

where by prime we denote $r$ derivative. The above equation admits the following unique solution

$$h'(r) = \frac{q}{\sqrt{r^2}}g(r), \quad (2.15)$$

where we denote the constant of integration by $q$, since it should be related to the electric charge of the black hole. Hence from (2.13), we obtain

$$F_{tr} = \Xi \frac{q}{r^2} g(r), \quad F_{\varphi r} = -\frac{a}{r^2} q g(r).$$  \hfill (2.16)

Inserting metric (2.10), condition (2.11), and the electromagnetic fields (2.16) into the field equations (2.8), we arrive at the following equations for the non-vanishing components of the gravitational field equations

$$g f^2 \Xi^2 \left[ 2 r^3 f' + 2 f r^2 + \nabla (\phi) r^4 + 2 q^2 \right] + a^2 g \left( -2 r^3 f' - r^4 f'' - r^4 V(\phi) + 2 q^2 \right)$$

$$= \frac{1}{2} \left( -2 r^4 f g'' - 2 r^3 f g' - 3 r^4 f' g' \right) \equiv 0, \quad (2.17)$$

$$3 r^3 g f' + 2 r^3 f g' + r^2 g f + 3 r^4 f' g' + 2 r^4 f g'' + r^4 g f'' + \frac{3}{2} r^4 g V(\phi) - q^2 g = 0.\quad (2.18)$$

$$\Xi^2 \left[ 2 r^3 (fg)' + 3 r^4 f g' + 2 r^4 f g'' + r^4 g f'' + r^4 g V(\phi) - 2 q^2 g \right]$$

$$- a^2 g \left( 2 r^3 f' + 2 r^2 f + r^4 V(\phi) + 2 q^2 \right) = 0, \quad (2.19)$$

$$2 r^3 (fg)' + 3 r^4 f g' + 2 r^4 f g'' + r^4 g f'' + r^4 g V(\phi) = 2 q^2 g = 0, \quad (2.20)$$

- 5 -
\[ \Xi a \left( 3r^4 f'g' - 2gf r^2 - 4q^2 g + 2r^3 fg' + r^4 gg'' + 2r^4 f g'' \right) = 0. \]  \tag{2.21}

Our aim here is to solve the above field equations and obtain the unknown functions \( f(r) \) and \( g(r) \). Clearly, our solutions should also satisfy Eq. (2.9) for the scalar field. During this paper we consider the case for which the potential is constant, namely, \( V(\phi) = V_0 = -2\Lambda \), where for later convenience we assume this constant to be positive definite, i.e. \( \Lambda = 3/l^2 > 0 \).

Multiplying Eq. (2.20) by factor \( \Xi^2 l^2 \) and subtracting the resulting equation from (2.19), we arrive at

\[ r^3 f' + r^2 f + \frac{r^4}{2} V(\phi) + q^2 = 0. \] \tag{2.22}

Substituting \( V(\phi) = -2\Lambda \) in Eq. (2.22), and solving for \( f(r) \), we find

\[ f(r) = -\frac{m}{r} + \frac{q^2}{r^2} + \frac{\Lambda}{3} r^2, \] \tag{2.23}

where \( m \) and \( q \) are integration constants which are, respectively, related to the mass and charge of the black string. Inserting solution (2.23) into Eq. (2.18), we find the following equation for the metric function \( g(r) \):

\[ (2\Lambda r^5 - 6mr^2 + 6q^2 r)g'' + (8\Lambda r^4 + 3mr - 12q^2)g' = 0. \] \tag{2.24}

Solving yields

\[ g(r) = c_1 + c_2 \int \frac{r^2 dr}{(\Lambda r^4 - 3mr + 3q^2)^{3/2}}, \] \tag{2.25}

where \( c_1 \) and \( c_2 \) are the constants of integration. In the limiting case where \( c_2 = 0 \), our solution is nothing but the corresponding one of Einstein gravity which is indeed the solution obtained in [28]. Without loss of generality we can set \( c_1 = 1 \). Indeed, the effects of \( c_1 \) in function (2.25) can be absorbed by rescaling \( t \to t/c_1 \) and \( \varphi \to \varphi/c_1 \) in the line element (2.10). Thus, we rewrite the general solution as

\[ g(r) = 1 + b \int \frac{r^2 dr}{(\Lambda r^4 - 3mr + 3q^2)^{3/2}}, \] \tag{2.26}

where \( b \) is a constant which reflects the imprint of the mimetic field in the solutions. One can easily check that the obtained solutions (2.23) and (2.26) are fully satisfied the field equations (2.9) and (2.17)-(2.21). Since the integral in the function (2.26) cannot be calculated easily, we consider in the following two sections the uncharged and charged rotating black strings, separately.

3 Uncharged mimetic black string

In this case \( (q = 0) \), the field Eq. (2.24) reduces to

\[ (2\Lambda r^5 - 6mr^2)g'' + (8\Lambda r^4 + 3mr)g' = 0, \] \tag{3.1}
which admit the following solution
\[ g(r) = 1 + \frac{b_0 \, r^{3/2}}{\sqrt{\Lambda r^3 - 3m}}, \quad (3.2) \]
where \( b_0 \) is a constant with dimension \([\text{length}]^{-1}\) which incorporates the imprint of the mimetic field on the spacetime metric. The horizon is determined by \( f(r_+) = 0 \), which leads to \( r_+ = (3m/\Lambda)^{1/3} \). Let us note that \( g(r) \) diverges at \( r_+ \). Indeed \( r_+ \) is a coordinate singularity and all curvature invariants have finite values at \( r_+ \). From expression \( g(r) \) we see that the solution is ill-defined for \( r < r_+ \). Therefore, one may exclude the region \( 0 < r < r_+ \) from the spacetime by redefinition of the coordinate \( r \rightarrow \rho = \left( r^3 - r_+^3 \right)^{1/3} \). Let us note that \( g(r) \) diverges at \( r_+ \). Indeed \( r_+ \) is a coordinate singularity and all curvature invariants have finite values at \( r_+ \). From expression \( g(r) \) we see that the solution is ill-defined for \( r < r_+ \). Therefore, one may exclude the region \( 0 < r < r_+ \) from the spacetime by redefinition of the coordinate \( r \rightarrow \rho = \left( r^3 - r_+^3 \right)^{1/3} \). Thus, in the new coordinate \( \rho = 0 \) corresponds to \( r = r_+ \), and the spacetime is regular for \( \rho > 0 \).

In order to see the asymptotic behavior of the solutions, we consider the non-rotating case \((a = 0)\), where the line elements of the black string is given by
\[ ds^2 = -f(r)g^2(r)dt^2 + \frac{dr^2}{f(r)} + r^2(d\varphi^2 + \frac{dz^2}{r^2}). \quad (3.3) \]
Therefore, the \((tt)\) component of the static black string is given by \(-\mathbf{g}_{tt} = f(r)g^2(r) = B(r)\), where
\[ B(r) = \left( -\frac{m}{r} + \frac{\Lambda r^2}{3} \right) \left[ 1 + \frac{b_0 \, r^{3/2}}{\sqrt{\Lambda r^3 - 3m}} \right]^2. \quad (3.4) \]
Expanding \( g(r) \) and \( B(r) \) for large values of \( r \), we arrive at
\[ g(r) \approx 1 + \frac{b_0 \, r^{3/2}}{\sqrt{\Lambda} r^{1/3}} + \frac{3mb_0}{2\Lambda^{3/2}r^3} + O\left( \frac{1}{r^6} \right), \]
\[ B(r) \approx r^2\left( \Lambda + b_0^2 + 2b_0\sqrt{\Lambda} \right) - \frac{m}{r} \left( 1 + \frac{b_0 \sqrt{\Lambda}}{r^3} \right) + O\left( \frac{1}{r^4} \right). \]
Thus as \( r \to \infty \), the asymptotic behaviour of the solutions is not exactly AdS space\(^1\) and get modified due to the presence of the mimetic field \( \phi \) which its imprint incorporates in the metric functions via the constant \( b_0 \). Roughly speaking, we can see that the asymptotic behaviour of uncharged black string in mimetic gravity is approximately AdS, unless in the limiting case where \( b_0 = 0 \), the asymptotic behaviour of the solutions become AdS. As we shall see later, this asymptotic behaviour has a crucial effect on the conserved quantities of the spacetime.

It is also interesting to calculate the curvature scalars of this spacetime. Expanding the Ricci scalar and the Kretschmann invariant around \( r = 0 \), we arrive at
\[ \lim_{r \to 0} R = \frac{\text{const.}}{\sqrt{r^3}} - 4\Lambda + b_0^2 + \cdots, \]
\[ \lim_{r \to 0} R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} = \frac{12m^2}{r^6} - \frac{17mb_0^2}{r^3} + \cdots \]
\(^1\)For asymptotic AdS spacetime one expects \( f(r) = B(r) \approx \Lambda r^2/3 \). In this paper, our notation is such that we have defined \( \Lambda = -3/l^2 > 0 \), and therefore \( \Lambda > 0 \) corresponds to AdS space. The reason for this choice is that the term \( \sqrt{\Lambda} \) appears in our solutions, which implies that it should be positive definite.
Thus, both curvature invariants diverge as \( r \to 0 \), which confirms that there is an essential singularity located at \( r = 0 \). On the other side, for the asymptotic region where \( r \to \infty \), the invariants of the spacetime are obtained as

\[
\lim_{r \to \infty} R = -4\Lambda, \quad \lim_{r \to \infty} R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} = \frac{8}{3}\Lambda^2,
\]

It is also easy to show that Ricci and Kretschmann invariants have finite values on the horizon \( r_+ \). Having a look on Eq. (3.4), one may wonder that at the horizon, the function \(-g_{tt}(r) = B(r)\) diverge and the metric becomes singular. However, this is indeed not the case. Simplifying the metric function (3.4), it can be rewritten

\[
B(r) = \left( \frac{\sqrt{\Lambda r^3 - 3m + b_0 r^{3/2}}}{3r} \right)^2
\]

which clearly has a finite value at \( r_+ \). Furthermore, from the above expression we observe that \( B(r) \) is well-defined for \( r > r_+ \) and has a minimum value \( B(r) \big|_{\text{min}} = b_0^2 r_+^2 / 3 \) at the horizon.

One may also look for the surface where the redshift becomes infinite. The infinite redshift surface is the surface where clock intervals in flat space correspond to infinite time intervals on the infinite redshift surface. More precisely, for an emitter \( E \) and receiver \( R \) with fixed spatial coordinates in a stationary spacetime, the gravitational frequency shift of a photon is, quite generally, given by [52]

\[
\frac{\nu_R}{\nu_E} = \left[ \frac{g_{tt}(A)}{g_{tt}(B)} \right]^{1/2},
\]

where \( A \) is the event at which the photon is emitted and \( B \) the event at which it is received. Thus, we see that if the photon is emitted from a point with fixed spatial coordinates, then \( \nu_R \to 0 \) in the limit \( g_{tt} \to 0 \), so that the photon suffers an infinite redshift. Thus a surface defined by \( g_{tt} = 0 \) is also often called an infinite redshift surface. For the Schwarzschild spacetime, both an infinite redshift surface and event horizon coincide, but in more general axisymmetric spacetime such as Kerr black holes these surfaces do not coincide. In our case, by setting \(-g_{tt} = B(r) = 0\), we find that the surface of infinite redshift is given by

\[
r_s = \left( \frac{3m}{\Lambda - b_0^2} \right)^{1/3}.
\]

Thus the infinite redshift surface only exist provided we have \( \Lambda > b_0^2 \). It can be seen that for \( b_0 = 0 \) the infinite redshift surface coincides with the event horizon. This is indeed an expected result, since in this case our solutions reduce to black string solutions of Einstein gravity. The behaviour of the metric functions \( f(r) \) and \( g(r) \) are depicted in Figs. 1-3. From Figs. 1 and 2 we see that rotating black string in mimetic gravity has only one horizon at finite radius \( r_+ \) where \( f(r) \) and hence \( B(r) = f(r)g^2(r) \) change sign on it. We observe that with increasing \( m \) or decreasing \( \Lambda \), the radius of this horizon increases as well.
which can be easily understood from its definition. Besides, as $r \to 0$, the metric function diverges, which confirm that there is a singularity at $r = 0$ which already confirmed that it is indeed an essential singularity. Finally, from Fig. 3 it is observed that the function $g(r)$ approach to constant value $1 + b_0/\sqrt{\Lambda}$ in large $r$ limit.

We finish this section by calculating the mass and angular momentum of the rotating mimetic black strings. We shall use the counterterm method inspired by AdS/CFT correspondence. In our case the suitable boundary term which removes the divergences of the action can be written

$$S_b = \frac{1}{8\pi} \int_{\partial M} d^3 x \sqrt{-\gamma} \left( \Theta(\gamma) + \frac{2}{7} \right),$$

(3.13)

where $\Theta$ is the trace of the extrinsic curvature $\Theta^{\mu\nu}$ for the boundary $\partial M$ and $\gamma$ is the
induced metric on the boundary. The second term in (3.13) is the suitable counterterm. Variation of the action (3.13) with respect to boundary metric $\gamma_{\mu\nu}$ yields the following finite stress-energy tensor \[ T^{ab} = \frac{1}{8\pi} \left[ \Theta^{\mu\nu} - \Theta^{\mu}_{\gamma^{\mu\nu}} + \frac{2}{7} \gamma^{\mu\nu} \right]. \] (3.14)

In order to compute the conserved charges of the spacetime, we choose a spacelike surface $\mathcal{B}$ in the boundary $\partial \mathcal{M}$ with metric $\sigma_{ij}$, and write the boundary metric in ADM (Arnowitt-Deser-Misner) form:

$$\gamma_{ab}dx^a dx^a = -N^2 dt^2 + \sigma_{ij} (d\varphi^i + V^i dt) (d\varphi^j + V^j dt),$$

where the coordinates $\varphi^i$ are the angular variables parameterizing the hypersurface of constant $r$ around the origin, and $N$ and $V^i$ are the lapse and shift functions respectively. For the Killing vector field $\xi$ on the boundary, the quasilocal conserved quantities associated with the stress tensors of Eq. (3.14) are given by [43]

$$Q(\xi) = \int_{\mathcal{B}} d^2x \sqrt{\sigma} T_{ab} n^a \xi^b, \quad (3.15)$$

where $\sigma$ is the determinant of the metric $\sigma_{ij}$, $\xi$ and $n^a$ are, respectively, the Killing vector field and the unit normal vector on the boundary $\mathcal{B}$. For boundaries with timelike ($\xi = \partial/\partial t$) and rotational ($\varsigma = \partial/\partial \varphi$) Killing vector fields, one obtains the conserved mass and angular momenta of the system enclosed by the boundary $\mathcal{B}$ as [43]

$$M = \int_{\mathcal{B}} d^2x \sqrt{\sigma} T_{ab} n^a \xi^b, \quad (3.16)$$
$$J = \int_{\mathcal{B}} d^2x \sqrt{\sigma} T_{ab} n^a \varsigma^b. \quad (3.17)$$

**Figure 3.** The behavior of $g(r)$ for rotating black string. Here we have taken $b_0 = 1/2$ and $m = 2$. 
It is important to note that both $M$ and $J$ are independent of the particular choice of foliation $B$ within the surface $\partial M$ while they depend on the location of the boundary $B$ in the spacetime. Then, it is a matter of calculations to show that the mass and angular momentum per unit length of the rotating string when $B \to \infty$ are given by

$$M = \frac{(3\Xi^2 - 1)m}{16\pi l} + \frac{b_0 m \sqrt{3}}{24\pi}, \quad (3.18)$$

$$J = \frac{3\sqrt{\Xi^2 - 1}m}{16\pi}, \quad (3.19)$$

where we have also used $\Lambda = 3/l^2$. When $a = 0$ ($\Xi = 1$), the angular momentum per unit volume vanishes, which confirms that parameter $a$ is indeed the rotational parameter of the black string. Compared to the mass and angular momentum of black string solutions of Einstein gravity [42, 43], we see that the angular momentum do not change, while the mass get an additional term. When $b_0 = 0$, the mass also reduces to the one of Einstein gravity [42, 43].

4 Charged mimetic black string

Now we consider the general solutions given by (2.23) and (2.26). Since we are looking for the analytical solutions and the integral in (2.26) cannot be done analytically, we study the behaviour in two ranges. For large $r$, the dominant term in the integrand is $\Lambda r^4$ and we have

$$g(r) = 1 + b \int \frac{r^2 dr}{(\Lambda r^4 - 3mr + 3q^2)^{3/2}} \approx 1 + \frac{b}{\Lambda^{3/2}} \int \frac{dr}{r^4} + \cdots \approx 1 - \frac{b}{3\Lambda^{3/2}} \frac{1}{r^3} + \cdots \quad (4.1)$$

Thus the metric function $B(r) = f(r)g^2(r)$, for large $r$, is

$$B(r) = -\frac{m}{r} + \frac{q^2}{r^2} + \frac{\Lambda r^2}{3} - \frac{2b}{9\sqrt{\Lambda}} + O\left(\frac{1}{r^4}\right), \quad (4.2)$$

which contains an additional term of $O(1/r)$ compared to charged rotating black string solution of Einstein gravity [42]. This term reflects the imprint of mimetic field on the spacetime. We observe that the asymptotic behaviour of the solutions is AdS which differs from the uncharged case where the spacetime was approximately asymptotically AdS. On the other hand when $r \to 0$, we can neglect the term $\Lambda r^4$ and the solution becomes

$$g(r) \approx 1 + b \int \frac{r^2 dr}{(3q^2 - 3mr)^{3/2}} \approx 1 + \sqrt{3}b \left[ 2 \left(\frac{2q}{3m}\right)^3 + \left(\frac{r}{3q}\right)^3 + \cdots \right], \quad (4.3)$$

and thus

$$B(r) \approx \left( -\frac{m}{r} + \frac{q^2}{r^2} + \frac{\Lambda r^2}{3} \right) \left\{ 1 + \sqrt{3}b \left[ 2 \left(\frac{2q}{3m}\right)^3 + \left(\frac{r}{3q}\right)^3 + \cdots \right] \right\}^2. \quad (4.4)$$
From (4.5) we observe that near the singularity where \( r \to \infty \), we have \( B(r) \to \infty \), as one expected. When \( b = 0 \), our solutions given in (4.3) and (4.5) reduce to asymptotically AdS charged black string of Einstein gravity.

The horizon can be obtained by solving \( f(r) = 0 \), where \( f(r) \) is given by Eq. (2.23). Thus, the horizons are the real root of equation \( \Lambda r^4 - 3mr + 3q^2 = 0 \). Depending on the values of the parameters this equation may have zero, one or two roots. The cases with zero or one root correspond to naked singularity and extremal black hole, respectively. When this equation has two roots we encounter a black hole with two inner and outer horizon.

**Figure 4.** The behavior of \( f(r) \) for charged rotating black string with different \( q \), where we have taken \( m = 3, \Lambda = 2 \).

**Figure 5.** The behavior of \( B(r) = f(r)g^2(r) \) for charged rotating black string given in Eq. (4.3) with different \( q \). Here we have taken \( m = 2, b = 3 \) and \( \Lambda = 1 \).
Figure 6. The behavior of $g(r)$ for charged rotating black string for large $r$ limit with $\Lambda = 2$.

Figure 7. The behavior of $F_{tr}(r)$ for charged rotating black string for different $q$. Here we have taken $b = 1$, $\Lambda = 2$, $\Xi = 1.2$.

The behavior of the metric functions for charged rotating black string are depicted in Figs. 4-6. From Fig. 4, we see that, depending on the metric parameters, our solutions can represent black string with two horizons, an extremal black string or naked singularity. From Fig. 5, we also observe that our solutions admit two, one or zero surface of infinite redshift if the metric parameters are chosen suitably. We have also plotted the behavior of $g(r)$ in Fig. 6, where it can be seen that $g(r) \to 1$ for large values of $r$ and goes to $-\infty$ as $r \to 0$.

Given the function $g(r)$, the explicit form of the electric field, for large $r$, is given by

$$F_{tr} = \frac{q\Xi}{r^2} \left[ 1 - \frac{b}{3\Lambda^{3/2} r^3} \frac{1}{r^3} + O \left( \frac{1}{r^5} \right) \right].$$

(4.6)
Figure 8. The behavior of $F_{tr}(r)$ for charged rotating black string for different parameter $b$. Here we have taken $q = 1.5$, $\Lambda = 2$, $\Xi = 1.2$.

Let us note that for $b \neq 0$, the electric field has a maximum value at $r_{\text{max}} = \left(\frac{5b}{6\Lambda^{1/2}}\right)^{1/3}$, and goes to zero as $r \to \infty$. This maximum value appears since the imprint of the mimetic field which contributes to the second negative term of (4.6) reduces the electric field compared to the case of Einstein gravity. Figs. 7 and 8 demonstrate the behaviour of the electric field $F_{tr}(r)$ for charged rotating mimetic black strings. From these figures we observe that the maximum value of electric field increases with increasing $q$, while it decreases and shifts to larger $r$ with increasing $b$. This can be understood since for larger $b$ the effects of the mimetic field makes the electric field weaker. The large $r$ limit behaviour of the metric functions as well as $F_{tr}(r)$ and $F_{\varphi r}(r)$ indicate that far from the black string ($r \gg r_+$), the effects of the mimetic field disappear and one recovers the Einstein gravity up to a constant.

We then look for the curvature singularity. To do that, we expand the scalar invariants for the obtained solutions,

$$\lim_{r \to 0} R = -\frac{126q^2}{r^4} + \cdots$$

$$\lim_{r \to 0} R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} = \frac{26124q^4}{r^8} + \cdots$$

Therefore, we have an essential singularity located at $r = 0$. On the other side, for the asymptotic region where $r \to \infty$, the invariants of the spacetime are obtained as

$$\lim_{r \to \infty} R = -4\Lambda,$$

$$\lim_{r \to \infty} R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} = \frac{8}{3}\Lambda^2.$$
unit length of the charged rotating black string are given by

\[ M = \frac{(3\Xi^2 - 1)m}{16\pi l} + \frac{b(\Xi^2 - 1)\sqrt{3}}{72\pi}, \]  
\[ J = \frac{\Xi\sqrt{\Xi^2 - 1}(27m + 2\sqrt{3}bl)}{144\pi}. \]

(4.11)  
(4.12)

When \( b = 0 \), the above expressions for the mass and angular momentum restore their respective expressions in Einstein gravity. Let us note that \( M \) and \( J \) differ for charged and uncharged rotating black strings. This may due to the fact that the asymptotic behaviour of these two classes of solutions are different. For the uncharged string, the asymptotic behaviour is approximately AdS, while for charged rotating string, the solutions are asymptotically AdS. However, this issue deserves further investigation.

5 Conclusion and discussion

In conclusions, we have obtained two new classes of rotating black string solutions in the context of mimetic gravity and in the presence of a constant potential, \( V(\phi) = -2\Lambda \) for the mimetic field \( \phi \). We first, derived exact analytical solutions for uncharged rotating black string and investigated their physical properties. In this case, we found that the imprint of the mimetic field on the gravitational field equations makes a deviation from the AdS space for the the asymptotic behaviour of the solution and yields an approximately AdS spacetime. We also obtained the surface of infinite red shift and observed that it is different from the event horizon and only exist for \( \Lambda > b_0^2 \). When \( b_0 = 0 \), the infinite redshift surface coincides with the event horizon. Then, we explored charged rotating mimetic black string. In this case we could obtain analytical solutions, after expanding the integrand in Eq. (2.26), namely for large/small values of \( r \). In this case our solution is asymptotically AdS and may have no horizon (naked singularity), one or two horizons depending on the metric parameters. Besides, both electric field \( F_{tr} \) and magnetic field \( F_{\varphi r} \) diverge for small \( r \), they have a maximum value at finite \( r \) and go to zero as \( r \to \infty \).

For both class of solutions, we also observed that the Kretschmann invariant \( R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} \) and the Ricci scalar diverge at \( r = 0 \), and they are finite for \( r \neq 0 \). Thus, there is a n essential singularity located at \( r = 0 \). Besides, \( R_{\mu\nu\rho\sigma}R^{\mu\nu\rho\sigma} \to 8\Lambda^2/3 \) and \( R \to -4\Lambda \) as \( r \to \infty \). In the absence of the mimetic field, our solutions reduce to the asymptotically AdS rotating black string in Einstein gravity [42, 43]. We also calculated the mass and angular momentum per unit length of the rotating black strings which has an additional term compared to the case of rotating string in Einstein gravity [42, 43].

Let us confess that we also made some attempts to construct exact analytical solutions in case of variable potential, e.g., \( V(\phi(r)) = V(r) \). Unfortunately, we failed to find exact analytical solutions which fully satisfy the field equations \(^2\). For instance, if we examine

\(^2\) Note that the obtained solutions in Ref. [19] are not exact analytical solutions, and only valid for some ranges of \( r \). Indeed they constructed potential for the mimetic field, by using an inverse approach, i.e., by guessing a metric function and inserting it into the field equations to derive the functional form of the
\[ V = -2\alpha r^{-n} \] we obtain, for uncharged case \((q = 0)\), the following solution for Eq. (2.22)

\[ f(r) = \frac{\alpha r^{2-n}}{3-n} - \frac{c_1}{r} \] \hspace{1cm} (5.1)

Then depending on the value of \(n\), one can solve the field equations (2.17)-(2.21) to obtain the function \(g(r)\). For instance, for \(n = 2\) these equations admit the following consistent unique solution

\[ g(r) = c_1 + 2\alpha r + \frac{c_2 r^{3/2}}{\sqrt{\alpha r - c_1}}, \] \hspace{1cm} (5.2)

where \(c_1\) and \(c_2\) are integration constants \(^3\). The main challenge is that the obtained solutions for variable potential do not satisfy the equation of motion (2.9) of the scalar field. We have examined a wide range of functions for the potential and arrived at the same conclusion; the obtained solutions from the Einstein equations (2.8) do not satisfy the equation of motion (2.9) for the scalar field. This may be due to the nature of mimetic gravity which implies that \(\phi\) is not a dynamical scalar field by itself, but only makes the longitudinal mode of gravity to be dynamical. However, this issue is not well settle down and certainly needs further clarification.

Many issues are remained for future investigations. First of all, this study can be generalized to higher dimensional spacetime by exploring the rotating black branes/holes in the framework of mimetic gravity. One may also try to derive \((2 + 1)\)-dimensional BTZ like solutions of mimetic gravity. Investigation the geodesic motion of massless and massive particles around this spacetime is also another task. It is also interesting to explore thermodynamics, thermal stability, and phase transition of mimetic black holes/strings. We leave these issue for future studies.
