Abstract
Quantum entanglement is among the most fundamental, yet from classical intuition also most surprising properties of the fully quantum nature of physical reality. We report several experiments performed on IBM’s Quantum Experience demonstrating envariance – entanglement assisted invariance. Envariance is a recently discovered symmetry of composite quantum systems, which is at the foundational origin of physics and a quantum phenomenon of pure states. These very easily reproducible and freely accessible experiments on Quantum Experience provide simple tools to study the properties of envariance, and we illustrate this for several cases with “quantum universes” consisting of up to five qubits.

Keywords: Quantum mechanics

1. Introduction

Entanglement – at the foundational origin of physics

In many aspects classical intuition fails to describe the fully quantum nature of physical reality. In particular, the way quantum states share information and how they are correlated can at times be a bit “spooky” [1, 2]. However, nowadays there is little doubt that quantum entanglement is real [3, 4], and that the quantum mechanical description of physical reality is, indeed, complete [5, 6, 7].
Although quantum entanglement might be counterintuitive from a classical point of view, its very nature is at the core of the foundations of physics. For instance, it has been well-established that statistical mechanics is deeply rooted in properties and consequences of entangled quantum states [2, 8, 9, 10, 11], and quantum entanglement is essentially what will make potential quantum computers work [12].

An important and at the same time particularly peculiar consequence of entanglement is the existence of purely non-classical symmetries. Consider a quantum system, $S$, which is fully entangled with an environment, $E$, and let $|ψ_{SE}\rangle$ denote the composite state in a “quantum universe”, $S \otimes E$. Then $|ψ_{SE}\rangle$ is called envariant under a unitary map $U_S = u_S \otimes I_E$, if $|ψ_{SE}\rangle$ exhibits entanglement assisted invariance under $U_S$.

By this we mean that $|ψ_{SE}\rangle$ is invariant under $U_S$, if there exists another unitary $U_E = I_S \otimes u_E$ which only acts on $E$ but not on $S$ such that,

$$U_S |ψ_{SE}\rangle = (u_S \otimes I_E) |ψ_{SE}\rangle = |η_{SE}\rangle$$

$$U_E |η_{SE}\rangle = (I_S \otimes u_E) |η_{SE}\rangle = |ψ_{SE}\rangle.$$  \hspace{1cm} (1)

Thus, $U_E$ “does the job” of the inverse map of $U_S$ on $S$—assisted by the quantum environment $E$, see Eq. (1). This quantum symmetry, aka envariance [13] is a symmetry of pure quantum states, which has no direct classical analog. Pure states of classical, composite systems are given by Cartesian, rather than by tensor products, and hence such an environment assisted inverse cannot exist [14].

The importance of envariance for the foundations of physics can hardly be underestimated. Originally discovered in a derivation of Born’s rule [13, 14, 15, 16], it quickly became clear that the emergence of classical reality from quantum physics is deeply rooted in envariantly shared quantum information [17, 18, 19]. Nevertheless, the experimental demonstration of envariance poses formidable technological challenges that were only recently overcome in two (quantum) optical experiments [20, 21].

**Quantum computing in the cloud**

In May 2016 IBM made a fully functional, 5-qubit quantum computer publicly available via the world wide web [22]. The architecture is based on 5 transmon qubits in a star geometry, and a full Clifford algebra is available [22]. The system is freely available through IBM’s cloud, and several experiments have already been reported, such as the verification of entropic uncertainty relations [23], the implementation of quantum error correction [24, 25], the experimental test of Mermin inequalities [26], “easy” quantum state tomography [27], and a demonstration of quantum teleportation [28].
Envariance in the cloud

In this paper we report a simple and easily reproducible demonstration of envariance on IBM’s Quantum Experience. Thus, the purpose of this demonstration is twofold: (i) we report a freely accessible, and pedagogical experiment demonstrating properties of entanglement with the first quantum computer in the cloud, and (ii) we demonstrate envariance in a “universe” consisting of up to five qubits, which goes beyond the technically challenging experiments in quantum optics, which (so far) have been restricted to only two qubits.

In the following we briefly describe the 5-qubit quantum computer in Sec. 2, before we report the outcome of several experiments demonstrating envariance in Sec. 3. The analysis is concluded with a few remarks in Sec. 4.

2. Background

In May 2016 IBM made a universal quantum computer available to the public via the IBM cloud [22, 29], and which is housed at the IBM T.J. Watson Research Center in New York [29]. Currently, Quantum Experience consists of 5 transmon qubits [30, 31], that are connected in a star geometry. Principally, a full Clifford algebra [32] is available, with the exception that the CNOT gate can only be performed on the center qubit with any of the four peripheral qubits.

Programming the quantum computer is conveniently provided via a graphical user interface, which IBM dubbed the composer. The interface is so accessible and operational that it has been suggested that now any undergraduate student could perform experiments on a “real-life quantum computer” [28]. However, the system is robust enough to also allow research experiments [25], and in particular the demonstration of quantum entanglement [26]. Quantum Experience is calibrated daily, and typically its temperature is around a few mK and the decoherence times of the single qubits are about 50–100 μs.

However, it should be emphasized that a shortcoming of Quantum Experience is that only projective measurements of the single qubit states in z-direction qubits can be performed, i.e., it can be measured whether the single qubits are in |↑⟩ or |↓⟩. No quantum tomography for the joint state is available, which means that no direct measurements of correlations between qubits can be performed.

3. Experimental

As outlined above, envariance is a purely quantum symmetry of entangled quantum systems. A joint quantum state, |ψ_{SE}⟩ living in a “quantum universe”, S ⊗ E, is
called envariant under a unitary map, $U_S$, which acts only on the system, $S$, if the action of $U_S$ can be undone by another unitary acting only its complement $\mathcal{E}$. The principle is most easily illustrated with a simple example:

Suppose $S$ and $\mathcal{E}$ are each given by two-level systems, where $\{|\uparrow\rangle_S, |\downarrow\rangle_S\}$ are the eigenstates of $S$ and $\{|\uparrow\rangle_\mathcal{E}, |\downarrow\rangle_\mathcal{E}\}$ span $\mathcal{E}$. Now, further assume that $|\psi_{SE}\rangle \propto |\uparrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E} + |\downarrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E}$ and $U_S$ is a swap in $S - U_S$ “flips” $S$’s spin. Then, we have

\[
|\uparrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E} + |\downarrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E} \xrightarrow{U_S} |\downarrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E} + |\uparrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E}.
\] (2)

The action of $U_S$ on $|\psi_{SE}\rangle$ can be restored by a swap, $U_\mathcal{E}$, on $\mathcal{E}$,

\[
|\downarrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E} + |\uparrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E} \xrightarrow{U_\mathcal{E}} |\downarrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E} + |\uparrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E}.
\] (3)

Thus, the swap $U_\mathcal{E}$ on $\mathcal{E}$ restores the pre-swap $|\psi_{SE}\rangle$ without “touching” $S$, i.e., the global state is restored by solely acting on $\mathcal{E}$.

### 3.1. Swaps in multiple qubits

The above example can be readily implemented on Quantum Experience. We performed experiments with quantum “universes” consisting of 2, 3 and 5 qubits.

#### 3.1.1. Swaps in 2 qubits

We begin with the simplest situation, in which the quantum system $S$ is given by a single qubit, and the environment $\mathcal{E}$ is also only a single qubit.

Per default all qubits are prepared on Quantum Experience in the down state, and hence we first have to prepare $|\psi_{SE}\rangle \propto |\uparrow\rangle_S \otimes |\uparrow\rangle_\mathcal{E} + |\downarrow\rangle_S \otimes |\downarrow\rangle_\mathcal{E} \equiv |\uparrow\rangle + |\downarrow\rangle$.

The whole algorithm is depicted in Figure 1, which is taken from the graphical user interface of Quantum Experience. For this experiment qubit $Q_2$ was chosen as system $S$ and qubit $Q_1$ was chosen as environment $\mathcal{E}$.

Preparing the initial state, $|\psi_{SE}\rangle$, is achieved by applying a Hadamard-gate on one qubit ($Q_1$), followed by a CNOT operation entangling $S$ and $\mathcal{E}$. The first swap (2) is

---

1. Note that for the present purpose we use the word “swap” in the sense that it is illustrated in Eq. (2). This is the language coined the original papers by Zurek [10, 18]. Sometimes this operation is also called a “flip”, and “swap” is reserved for two qubit operations.
Figure 1. Depiction of a quantum algorithm equivalent to the envariant swap operation, cf. Eqs. (2)–(3). $Q_2$ is chosen as system, $S$, and $Q_1$ is the quantum environment, $E$. Per default all qubits are initially prepared in their ground states, $|\downarrow\rangle = |0\rangle$. Our desired initial state, $|\psi_{SE}\rangle \propto |\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle$, is obtained by performing a Hadamard-gate, $H$ (blue box) on $Q_1$, followed by a CNOT. The swap in $S$ is realized by a bitflip, i.e., a $\sigma_x$-gate ($X$ in Quantum Experience’s notation, green boxes), which can be counteracted by a bitflip in $E$. The pink boxes at the end of the algorithm depict the projective measurements of the qubits’ states.

Table 1. Relative frequencies of the final states obtained from the algorithm depicted in Figure 1 for several separate runs with either 1024 or 8192 shots; $B$ is the classical fidelity (4) with respect to the theoretically expected values.

|        | $|\downarrow\rangle$ | $|\uparrow\rangle$ | $|\downarrow\uparrow\rangle$ | $|\uparrow\downarrow\rangle$ | $B$  |
|--------|-----------------------|---------------------|-------------------------------|-------------------|------|
| theory | 0.5                   | 0                   | 0.5                           | 1                 |      |
| run 1  | 0.475                 | 0.046               | 0.037                         | 0.442             | 0.957|
| run 2  | 0.468                 | 0.043               | 0.041                         | 0.448             | 0.957|
| run 3  | 0.481                 | 0.042               | 0.035                         | 0.442             | 0.961|
| run 4  | 0.435                 | 0.053               | 0.057                         | 0.456             | 0.944|

then realized by performing a $\sigma_x$-gate on $S$, which can be “counteracted” by another $\sigma_x$-gate on $E$. Finally, the states of $S$ and $E$ are measured separately.\(^2\)

The algorithm was run 4 times for different peripheral qubits, with 1024 or 8192 shots, where 8192 is the maximal number of shots allowed on Quantum Experience for a “single run”. The results of the experiments are summarized in Table 1. To assess the quality of the experiment we compute the classical fidelity, i.e., the Bhattacharyya coefficient,\(^3\) which is given by [33]

$$B = \sum_i \sqrt{p_i q_i}.$$

(4)

where $p_i$ is the frequency of the observed states, {$|\downarrow\rangle, |\uparrow\rangle, |\downarrow\uparrow\rangle, |\uparrow\downarrow\rangle$}, and $q_i$ is the theoretical prediction $q_{\downarrow} = 0.5$, $q_{\uparrow} = 0$, $q_{\downarrow\uparrow} = 0$, and $q_{\uparrow\downarrow} = 0.5$. On average we obtained a fidelity of 95.5%.

\(^2\) Note again that Quantum Experience does not provide measurements of the joint state, but that qubits can only be measured separately.

\(^3\) Quantum Experience only provides projective measurements on single spins. Thus, full quantum tomography of the joint multi-qubit state is neither practical nor readily available.
Figure 2. Depiction of a quantum algorithm equivalent, which illustrates the importance of a judicious choice of the initial state. As before, $Q_2$ is chosen as system, $S$, and $Q_1$ is the quantum environment, $E$. However we start in $|\psi_{SE}\rangle = |\uparrow\rangle$. As in Figure 1 the unitaries $U_S$ and $U_E$ are given by $\sigma_x$-gates.

Table 2. Relative frequencies of the final states obtained from the algorithm depicted in Figure 2 for several separate runs with either 1024 or 8192 shots.

|       | $|\downarrow\downarrow\rangle$ | $|\downarrow\uparrow\rangle$ | $|\uparrow\downarrow\rangle$ | $|\uparrow\uparrow\rangle$ |
|-------|-------------------------------|-------------------------------|-------------------------------|-------------------------------|
| theory| 0                             | 0                             | 0                             | 1                             |
| run 1 (1024) | 0.001                         | 0.039                         | 0.032                         | 0.982                         |
| run 2 (8192) | 0.002                         | 0.036                         | 0.032                         | 0.931                         |

As a general observation we note that in both optical experiments [20, 21] higher fidelities were achieved. However, demonstrating envariance for two qubits on Quantum Experience poses hardly any technical challenge, and more complicated situations including higher dimensional systems can be studied as well.

**Counter example**

Before we move on to higher dimensional systems, however, we briefly illustrate the judicious choice of the initial states and the unitary maps. Envariance is a symmetry of quantum states, $|\psi_{SE}\rangle$, under a pair of unitary maps, $U_S$ and $U_E$. This means that if we apply the same map to a different initial state $|\tilde{\psi}_{SE}\rangle$ the map on $E$ does no longer act like the inverse of $U_S$, or more mathematically $|\tilde{\psi}_{SE}\rangle \neq U_E U_S |\psi_{SE}\rangle$.

To demonstrate the latter comment on Quantum Experience we omitted the initial state preparation, and acted with the two swap operation directly on the default ground state $|\tilde{\psi}_{SE}\rangle = |\downarrow\downarrow\rangle$, cf. Figure 2.

Table 2 summarizes the observed frequencies for several runs. We observe that rather then returning to the initial state $|\downarrow\downarrow\rangle$ the concocted map $U_E U_S$ produces $|\uparrow\uparrow\rangle$ (to very high probability).
Figure 3. Depiction of a quantum algorithm equivalent to the envariant swap operation, cf. Eqs. (5)–(6). $Q_2$ and $Q_1$ are chosen to span the system, $S$, and $Q_0$ is the quantum environment, $E$. Our desired initial state, $|\psi_{SE}\rangle \propto |\uparrow\uparrow\rangle_S \otimes |\uparrow\rangle_E + |\downarrow\downarrow\rangle_S \otimes |\downarrow\rangle_E \equiv |\uparrow\uparrow\rangle + |\downarrow\downarrow\rangle$, is obtained by performing a Hadamard-gates, $H$ (blue box) on $Q_1$ and $Q_2$, and an $\sigma_X$-gate (green box) on $Q_2$, followed by two CNOTs entangling $S$ and $E$, and concluded by final Hadamard-gates on all three qubits. The swap in $S$ is realized by two bitflips, i.e., two $\sigma_X$-gates in $S$, which can be counteracted by a single bitflip in $E$. The pink boxes at the end of the algorithm depict again the projective measurement of the qubits’ states.

3.1.2. Swaps in 3 qubits

As a second example we consider a situation, in which the system $S$ consist of two qubits, while the environment $E$ is still given by only a single qubit. In complete analogy to the previous example, we start with the GHZ-state, $|\psi_{SE}\rangle \propto |\uparrow\uparrow\rangle_S \otimes |\uparrow\rangle_E + |\downarrow\downarrow\rangle_S \otimes |\downarrow\rangle_E \equiv |\uparrow\uparrow\rangle + |\downarrow\downarrow\rangle$. As before, we will now demonstrate that such a state is envariant under a swap operation, namely

$$
|\uparrow\uparrow\rangle_S \otimes |\uparrow\rangle_E + |\downarrow\downarrow\rangle_S \otimes |\downarrow\rangle_E \xrightarrow{U_S} |\downarrow\downarrow\rangle_S \otimes |\uparrow\rangle_E + |\uparrow\uparrow\rangle_S \otimes |\downarrow\rangle_E .
$$

(5)

which can be restored by

$$
|\downarrow\downarrow\rangle_S \otimes |\uparrow\rangle_E + |\uparrow\uparrow\rangle_S \otimes |\downarrow\rangle_E \xrightarrow{U_E} |\downarrow\downarrow\rangle_S \otimes |\downarrow\rangle_E + |\uparrow\uparrow\rangle_S \otimes |\uparrow\rangle_E .
$$

(6)

The whole algorithm is depicted in Figure 3.

Table 3 summarizes the outcome of this experiment. We observe that while envariance is still evidently demonstrated the initial state is only restored with an average fidelity of 88.7%.

The lower fidelity is readily understood as a consequence of decoherence, which is more effective in the more complicated quantum system.
Table 3. Relative frequencies of the final states obtained from the algorithm depicted in Figure 3 for several separate runs with either 1024 or 8192 shots; $B$ is the classical fidelity \( (4) \) with respect to the theoretically expected values.

| State  | 1111 | 1101 | 1011 | 1001 | 0111 | 0101 | 0011 | 0001 | B     |
|--------|------|------|------|------|------|------|------|------|-------|
| theory | 0.5  | 0    | 0    | 0    | 0    | 0    | 0    | 0.5  | 1     |
| run 1  | 0.420| 0.029| 0.033| 0.056| 0.047| 0.062| 0.036| 0.316| 0.856 |
| run 2  | 0.427| 0.032| 0.016| 0.035| 0.038| 0.073| 0.021| 0.357| 0.885 |
| run 3  | 0.483| 0.021| 0.028| 0.016| 0.026| 0.040| 0.022| 0.365| 0.919 |

Figure 4. Depiction of a quantum algorithm equivalent to the envariant swap operation, cf. Eqs. \((7)-(8)\). $Q_4$, $Q_3$ and $Q_2$ are chosen to span the system, $S$, and $Q_1$ and $Q_0$ are the quantum environment, $\mathcal{E}$. The initial GHZ-state, $|\psi_{SE}\rangle \propto |1111\rangle_S + |1111\rangle_E$, is obtained by performing Hadamard-gates on $Q_4$, $Q_3$, $Q_1$ and $Q_0$, and a $\sigma_X$-gate on $Q_2$, followed by CNOTs entangling $S$ and $\mathcal{E}$, and concluded by final Hadamard-gates on all five qubits. The swap in $S$ is realized by three bitflips, i.e., three $\sigma_X$-gates in $S$, which can be counteracted by two bitflips in $\mathcal{E}$.

3.1.3. Swaps in 5 qubits

The largest “quantum universe” that can be realized on Quantum Experience consists of 5 qubits. Hence, we chose as a final example for envariant swaps the quantum system $S$ to comprise 3 qubits, which leaves 2 qubits for $\mathcal{E}$. Accordingly, we have,

$$
|111\rangle_S \otimes |\uparrow\downarrow\rangle_E + |1\downarrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E \xrightarrow{U_S} |1\uparrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E + |1\downarrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E.
$$

which can be restored by

$$
|1\downarrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E + |1\uparrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E \xrightarrow{U_E} |1\downarrow\downarrow\rangle_S \otimes |\downarrow\downarrow\rangle_E + |1\uparrow\downarrow\rangle_S \otimes |\uparrow\uparrow\rangle_E.
$$

The corresponding algorithm is depicted in Figure 4.
Table 4. Relative frequencies of the final states obtained from the algorithm depicted in Figure 4 for several separate runs with either 1024 or 8192 shots; B is the classical fidelity (4) with respect to the theoretically expected values.

|     | ivering | other | ivering | B  |
|-----|---------|-------|---------|----|
| theory | 0.5     | 0     | 0.5     | 1  |
| run 1 (8192) | 0.297   | 0.476 | 0.227   | 0.722 |
| run 2 (1024) | 0.273   | 0.501 | 0.227   | 0.706 |
| run 3 (8192) | 0.308   | 0.470 | 0.222   | 0.726 |
| run 4 (8192) | 0.348   | 0.376 | 0.276   | 0.789 |

The possible outcome for such an algorithm includes $2^5 = 32$ states, and therefore we only list the frequencies with which we obtained the theoretically expected states in Table 4. On average we only found the resorted state with a fidelity of 73.6%, and hence the demonstration is not quite as convincing as for the above two examples with smaller Hilbert spaces.

Our best guess is that the bigger aberrations originate in decoherence and non-perfect implementation of the single gates. This conjecture could be verified or falsified by performing the experiments in a such way that their durations become close to the single qubit decoherence time. This way, one would be able to quantify the effect the decoherence. Further analysis of our present results, however, without direct access to and benchmarking of the experimental systems is hardly feasible.

3.2. Other operations on 2 qubits

To conclude the analysis with two further examples we now return to the smallest “quantum universe”, in which $S$ and $E$ are given by single qubits. The next two examples elucidate that $|\psi_{SE}\rangle \propto |\uparrow\rangle_S \otimes |\uparrow\rangle_E + |\downarrow\rangle_S \otimes |\downarrow\rangle_E$ is not only invariant under swaps, cf. Eqs. (4)--(5), but actually under all unitary maps [10].

3.2.1. Creating and destroying superpositions

As a first example consider the algorithm of Figure 5. In comparison to the previous example in Figure 1 we replaced the bitflip operation by Hadamard-gates. Physically, Hadamard-gates can be understood as operations that create and destroy superpositions. One easily convinces oneself that $|\psi_{SE}\rangle \propto |\uparrow\rangle_S \otimes |\uparrow\rangle_E + |\downarrow\rangle_S \otimes |\downarrow\rangle_E$ is also invariant under $U_S = H_S \otimes I_E$, where $H = 1/2 (|\downarrow\rangle \langle \downarrow| + |\uparrow\rangle \langle \uparrow| + |\downarrow\rangle \langle \uparrow| - |\uparrow\rangle \langle \downarrow|)$ and $U_E = I_S \otimes H_E$.

In Table 5 we summarize our findings. We observe that once again envariance is demonstrated with an average fidelity of 95.8%. 
Figure 5. Depiction of a quantum algorithm equivalent to an invariant operation creating and destroying superpositions. $Q_2$ is chosen as system, $S$, and $Q_1$ is the quantum environment, $E$. As before, our desired initial state, $\psi_{SE} \propto |\downarrow\downarrow\rangle + |\uparrow\uparrow\rangle$, is obtained by performing a Hadamard-gate, $H$, on $Q_1$, followed by a CNOT.

Table 5. Relative frequencies of the final states obtained from the algorithm depicted in Figure 5 for several separate runs with either 1024 or 8192 shots; $B$ is the classical fidelity (4) with respect to the theoretically expected values.

|       | $|\downarrow\downarrow\rangle$ | $|\downarrow\uparrow\rangle$ | $|\uparrow\downarrow\rangle$ | $|\uparrow\uparrow\rangle$ | $B$     |
|-------|-------------------------------|-------------------------------|-------------------------------|-------------------------------|--------|
| theory| 0.5                           | 0                             | 0                             | 0.5                           | 1      |
| run 1 (1024) | 0.515                        | 0.036                         | 0.040                         | 0.409                         | 0.960  |
| run 2 (8192)  | 0.518                        | 0.036                         | 0.048                         | 0.398                         | 0.955  |

Figure 6. Depiction of a quantum algorithm equivalent to an invariant operation consisting of creating and destroying superpositions, and bitflips. $Q_2$ is chosen as system, $S$, and $Q_1$ is the quantum environment, $E$. In contrast to previous examples, here we chose the unitary map on $S$ to be given not only by a single gate, but rather as a concoction of a Hadamard-gate and a $\sigma_X$-gate, i.e., $U_S = H_S \cdot \sigma_X \otimes I_E$.

3.2.2. Superpositions and bitflips

Finally, we chose $U_S$ to be a concoction of a Hadamard-gate and a $\sigma_X$-gate, i.e., $U_S = H_S \cdot \sigma_X \otimes I_E$. The corresponding algorithm is illustrated in Figure 6.

Table 6 summarizes our findings. Envariance is observed with an average fidelity of 95.8%.
Table 6. Relative frequencies of the final states obtained from the algorithm depicted in Figure 6 for several separate runs with either 1024 or 8192 shots; $B$ is the classical fidelity (4) with respect to the theoretically expected values.

4. Conclusions

In the present analysis we have described six pedagogically chosen experiments on IBM’s Quantum Experience to elucidate a purely quantum symmetry. We have seen that demonstrating the concepts does not pose any technical challenges, and that these experiments can be reproduced with little effort. However, we have also seen that quality of the experimental outcome still lacks behind technically more challenging experiments in quantum optics. Vermeyden et al. [20] achieved Bhattacharya coefficients of $(99.963\pm0.005)\%$ and Harris et al. [21] $(99.15\pm0.41)\%$, whereas our experiments did not perform better than $96\%$. However, Quantum Experience has the advantage that it is very simple to operate and that principally “quantum universes” of up to five qubits are available. Our experiment with five qubits revealed that decoherence and (possibly) non-perfect implementation of the quantum gate are significant, and that even for the simplest possible example envariance could not be demonstrated convincingly.

In conclusion, we have reported a easily reproducible experiment that can provide a pedagogical access point to fundamental properties of quantum symmetries and a testbed for the possibilities and limitations of IBM’s Quantum Experience.

Declarations

Author contribution statement

Sebastian Deffner: Conceived and designed the experiments; Performed the experiments; Analyzed and interpreted the data; Contributed reagents, materials, analysis tools or data; Wrote the paper.

Funding statement

This work was supported by the U.S. National Science Foundation under Grant No. CHE-1648973 and IBM’s Quantum Experience.
Competing interest statement

The authors declare no conflict of interest.

Additional information

No additional information is available for this paper.

Acknowledgements

The views expressed are those of the author and do not reflect the official policy or position of IBM or the IBM Quantum Experience team.
