STABILITY AND PERTURBATIONS OF THE DOMAIN FOR THE FIRST EIGENVALUE OF THE 1-LAPLACIAN

EMMANUEL HEBEY AND NICOLAS SAINTIER

Let $\Omega$ be a smooth bounded domain in $\mathbb{R}^n$, $n \geq 2$. The 1-Laplacian on $\Omega$ is the formal operator

$$\Delta_1 u = -\text{div} \left( \frac{\nabla u}{|\nabla u|} \right)$$

we get by a formal derivation of $F(u) = \int_{\Omega} |\nabla u|dx$, or by letting $p \to 1$ in the definition of the $p$-Laplacian, $p > 1$. By analogy with the definition of the first eigenvalue $\lambda_{p,\Omega}$ of the $p$-Laplacian on $\Omega$, we define the first eigenvalue $\lambda_{1,\Omega}$ of the 1-laplacian on $\Omega$ by the minimization problem

$$\lambda_{1,\Omega} = \inf \left\{ \begin{array}{ll}
u & \in H^1_1(\Omega) \\
\int_{\Omega} |\nabla u|dx , \int_{\Omega} u |du| = 1 \end{array} \right. \quad (0.1)$$

where $H^1_1(\Omega)$ is the closure of $C^\infty_0(\Omega)$ in the Sobolev space $H^1_1(\Omega)$ of functions in $L^1(\Omega)$ with one derivative in $L^1$. By geometric measure theory, and the coarea formula, we also have that $\lambda_{1,\Omega} = h(\Omega)$, where $h(\Omega)$ is defined as the infimum of the ratio $|\partial D|/|D|$, $D$ varies over all smooth subdomains $D \subset \subset \Omega$, and $|\partial D|$ and $|D|$ are the $(n - 1)$-dimensional and $n$-dimensional measures of $\partial D$ and $D$. The result is known as Cheeger’s theorem [5], and $h(\Omega)$ is known as the Cheeger constant of $\Omega$ (see for instance Chavel [4]). Note the infimum in $h(\Omega)$ is not attained by a smooth subdomain $D \subset \subset \Omega$ since, if not, we may blow it up by a factor larger than one. This would decrease $h$, contradicting the optimality of $D$. Minimizers for $h(\Omega)$ touch the boundary $\partial \Omega$.

The main purpose of this paper is the study of the dependence of $\lambda_{1,\Omega}$ under perturbations of $\Omega$. The notion of perturbation is here quantified by mean of the 1-capacity. We provide results ranging from general type of perturbations to regular perturbations by diffeomorphisms. This type of problem has been widely studied in the case of the Laplacian, hardly in the case of the $p$-Laplacian and, as far as we know, has not been studied before in the case of the 1-laplacian. A natural space to study $\lambda_{1,\Omega}$ is $BV(\Omega)$, the space of functions of bounded variations (see, for instance, Evans and Gariepy [9], or Giusti [12]). By standard properties of the space $BV(\Omega)$, we can also define $\lambda_{1,\Omega}$ by the equation

$$\lambda_{1,\Omega} = \inf \left\{ u \in BV(\Omega) \right. \left. \int_{\Omega} |\nabla u|dx + \int_{\partial \Omega} |u|d\sigma \right. , \int_{\Omega} u |du| = 1 \quad (0.2)$$

Date: March 30, 2005.
Note here that if \( u \in BV(\Omega) \), and \( \overline{u} \) is the extension of \( u \) by 0 in \( \mathbb{R}^n \), then \( \overline{u} \in BV(\mathbb{R}^n) \) and

\[
\int_{\mathbb{R}^n} |\nabla u| dx = \int_{\Omega} |\nabla u| dx + \int_{\partial\Omega} |u| d\sigma \tag{0.3}
\]

By lower semicontinuity of the total variation, and compactness of the embedding \( BV(\Omega) \subset L^1(\Omega) \), it easily follows from (0.3) that the infimum in (0.2) is attained by some nonnegative \( u \in BV(\Omega) \). Then \( u \) is a solution of the equation \( \Delta u = \lambda_{1,\Omega} \) in the sense that there exists \( \Lambda \in L^\infty(\Omega, \mathbb{R}^n) \), \( \|\Lambda\|_\infty \leq 1 \), such that

\[
\begin{cases}
-\text{div}\Lambda = \lambda_{1,\Omega}, \quad u \geq 0, \\
\Lambda \nabla u = |\nabla u| \text{ in } \Omega, \quad \text{and}
\end{cases}
\]

\[
\begin{cases}
(\Lambda u)u = -|u| \text{ on } \partial\Omega,
\end{cases}
\]  

where \( \nu \) is the outer unit normal to \( \partial\Omega \), and \( \Lambda \nabla u \) is the distribution defined by integrating by parts \( \int_{\Omega} (\Lambda u)|\nabla u| dx \) when \( v \in C_0^\infty(\Omega) \) and \( \text{div}\Lambda \) makes sense. Moreover, see for instance Demengel [6], \( u \in L^\infty(\Omega) \) and, since \( \|u\|_1 = 1 \), there exists \( C = C(n, \Omega) \), \( C > 0 \), such that \( \|u\|_\infty \leq C \). We say \( u \) is an eigenfunction for \( \lambda_{1,\Omega} \).

Now define a Cacciopoli set in \( \Omega \) as a set \( \delta \subset \Omega \) such that \( \chi_D \in BV(\Omega) \), where \( \chi_D \) is the characteristic function of \( D \). Since \( \lambda_{1,\Omega} = h(\Omega) \), there are Cacciopoli sets \( D \subset \Omega \), e.g. the level sets of eigenfunctions, such that \( u = |D|^{-1}\chi_D \) is a minimizer for the right hand side in (0.2). Such sets are referred to as eigensets for \( \lambda_{1,\Omega} \) (and sometimes also as Cheeger’s sets). A general discussion about uniqueness and nonuniqueness of eigensets is in Fridman and Kawohl [10]. We refer also to Stredulinsky and Ziemer [18] (and to Belloni and Kawohl [3] for the \( p \)-Laplace case). Concerning regularity, possible references are Almgren [1], De Giorgi [8], Gonzales, Massari and Tamanini [13], and Stredulinsky and Ziemer [18]. By symmetrization, see Fridman and Kawohl [10] for details,

\[
\lambda_{1,\Omega} \geq n\omega_n^{1/n} |\Omega|^{-1/n},
\]

where \( \omega_n \) is the volume of the unit \( n \)-sphere.

Let \( K \) be a compact subset of \( \mathbb{R}^n \). The 1-capacity of \( K \), denoted by \( \text{cap}_1(K) \), is defined as the infimum of the \( L^1 \)-norm of \( |\nabla u| \), where the infimum is taken over all \( u \in C_0^\infty(\mathbb{R}^n) \) such that \( K \subset \text{int}\{u \geq 1\} \). Another possible definition (see, for instance, Maz'ja [10]) is that \( \text{cap}_1(K) = \inf |\partial\omega| \), where the infimum is taken over all smooth open bounded subset \( \omega \) such that \( K \subset \omega \). In particular, by the isoperimetric inequality, \( |K|^{(n-1)/n} \leq C\text{cap}_1(K) \), where \( C > 0 \) does not depend on \( K \) (but only on the dimension). For \( A \) and \( B \) two subsets of \( \mathbb{R}^n \), we denote by \( A \Delta B \) the symmetric difference of \( A \) and \( B \). Namely, \( A \Delta B = (A \setminus B) \cup (B \setminus A) \). Our first result deals with general type of perturbations of a domain. It states as follows.

**Theorem 0.1.** Let \( \Omega \) be a smooth bounded domain in \( \mathbb{R}^n \), \( (\Omega_\delta)_{\delta>0} \) be a sequence of smooth bounded domains in \( \mathbb{R}^n \), and \( K_\delta = \text{adh}(\Omega \Delta \Omega_\delta) \) be the closure of the symmetric difference \( \Omega \Delta \Omega_\delta \). Let \( (\Lambda_\delta) \) be a sequence of eigensets for the \( \lambda_{1,\Omega_\delta} \)'s. Assume \( \text{cap}_1(K_\delta) \rightarrow 0 \) as \( \delta \rightarrow 0 \). Then, for any \( \delta \),

\[
|\lambda_{1,\Omega_\delta} - \lambda_{1,\Omega}| = \frac{\varepsilon_\delta}{|A_\delta|} \text{cap}_1(K_\delta) + o(\text{cap}_1(K_\delta)) \tag{0.5}
\]

where \( \varepsilon_\delta \in [0, 1] \) for all \( \delta \), and \( |A_\delta| \geq \Lambda \) for some \( \Lambda > 0 \) and all \( \delta \). In particular, \( \lambda_{1,\Omega_\delta} \rightarrow \lambda_{1,\Omega} \) as \( \delta \rightarrow 0 \). Moreover, up to a subsequence, \( \chi_{A_\delta} \rightarrow \chi_A \) in \( L^1(\mathbb{R}^n) \) as \( \delta \rightarrow 0 \), where \( A \) is an eigenset for \( \lambda_{1,\Omega} \).
We stated the second part of Theorem 0.1 for characteristic functions of eigensets. However, note the convergence holds also for eigenfunctions. In Section 4 we prove that if the $u_\delta$s are eigenfunctions for $\lambda_{1,\Omega_\delta}$, then, up to a subsequence, with the notation in (0.3), $\nabla u_\delta \to \nabla u$ in $L^1(\mathbb{R}^n)$ as $\delta \to 0$, where $u$ is an eigenfunction for $\lambda_{1,\Omega}$.

We also get that the measures $\mu_\delta = |\nabla u_\delta|$ and $\mu = |\nabla u|$ satisfy $\mu_\delta \to \mu$ weakly as $\delta \to 0$.

A particular case of the general perturbations considered in Theorem 0.1 is when we consider domains with holes. Such domains (in the case of one ball) were considered by Sango [17] when discussing the first eigenvalue of the $p$-Laplacian operator, $p > 1$. For $A$ a Caccioppoli set, we let $\partial^* A$ be its reduced boundary, namely (see [2] or [12]) the subset of the boundary which is $C^1$ in a measure theoretic sense. For $x \in \mathbb{R}^n$ and $r > 0$, we let also $B_x(r)$ be the $n$-dimensional ball of center $x$ and radius $r$, and $b_n$ be the volume of the unit $n$-dimensional ball.

**Theorem 0.2.** Let $\Omega \subset \mathbb{R}^n$ be a smooth bounded domain in $\mathbb{R}^n$, $A$ be an eigenset for $\lambda_{1,\Omega}, x_1, \ldots, x_k$ be points in $\Omega$, $(\varepsilon_{i,\delta})_{i > 0}$, $i = 1, \ldots, k$, be $k$ sequences of positive real numbers converging to $0$ as $\delta \to 0$, $K_\delta = \bigcup_{i=1}^k B(x_i, \varepsilon_{i,\delta})$, $\Omega = \Omega \setminus K_\delta$. Assume there exists $i_0 = 1, \ldots, k$ such that $\varepsilon_{i,\delta} = O(\varepsilon_{i_0,\delta})$ for all $i = 1, \ldots, k$, $i \neq i_0$. Then, $\text{cap}_1(K_\delta) = \omega_{n-1} \varepsilon_{i_0,\delta}^{n-1} + o(\varepsilon_{i_0,\delta}^{n-1})$, and

$$\lambda_{1,\Omega} \leq \lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} + \frac{\omega_{n-1}}{|A|} \varepsilon_{i_0,\delta}^{n-1} + o\left(\varepsilon_{i_0,\delta}^{n-1}\right)$$

(0.6)

for all $\delta$. Moreover,

$$\lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} + \begin{cases} 
O\left(\varepsilon_{i_0,\delta}^{n-1}\right) & \text{if } x_{i_0} \in \text{int}(\Omega \setminus A) \\
\frac{\omega_{n-1}}{|A|} b_n \varepsilon_{i_0,\delta}^{n-1} + o\left(\varepsilon_{i_0,\delta}^{n-1}\right) & \text{if } x_{i_0} \in \partial^* A 
\end{cases}$$

(0.7)

where $\text{int}(\Omega \setminus A)$ is the interior of $\Omega \setminus A$, and $\partial^* A$ is the reduced boundary of $A$.

Needless to say, $\text{cap}_1(K_\delta) \to 0$ as $\delta \to 0$ and the convergence of eigensets (resp. eigenfunctions) stated in Theorem 0.1 holds true. Characterizations in dimension 2 of convex $\Omega$'s for which $\Omega = A$ (as a by-product for which $\Omega \setminus A \neq \emptyset$, and thus for which equation (0.7) is not empty) are in Bellettini, Caselles and Novaga [2], and Kawohl and Lachand-Robert [13]. When $\Omega$ is convex and $n = 2$, the eigenset $A = A_\Omega$ is unique. The domain $\Omega$ is said to be a calibrable set when $\Omega = A$. The ovoid domain $((x^2 + y^2)^2 < x^3)$ is a nice example in Kawohl and Lachand-Robert [13] of a noncalibrable set. With respect to the notation in Theorem 0.1 (0.7) gives that we can take $\varepsilon_{i_0} = 0$ if $x_{i_0} \in \text{int}(\Omega \setminus A)$, and $\varepsilon_{i_0} < 1/2$ if $x_{i_0} \in \partial^* A$. On the other hand, when $x_{i_0} \in \text{int}(A)$, the upper bound in (0.6) gives that we can take $\varepsilon_{i_0} = 1$, cannot (in general) be improved. If we let $\Omega = B_0(\varepsilon)$ and $K_\varepsilon = B_0(\varepsilon)$ be $n$-dimensional balls, $r > 0$, $0 < \varepsilon \ll 1$, then both $\Omega$ and the annulus $\Omega_\varepsilon = \Omega \setminus K_\varepsilon$ are calibrable sets (see, for instance, Kawohl and Lachand-Robert [13], Demengel, De Vuyst, and Motron [7]). In particular, the eigenvalues $\lambda_{1,\Omega}$ and $\lambda_{1,\Omega_\varepsilon}$ are given by $\lambda_{1,\Omega} = n/r$ and $\lambda_{1,\Omega_\varepsilon} = n(r^{n-1} + \varepsilon^{n-1})/(r^n - \varepsilon^n)$, and we get that

$$\lambda_{1,\Omega_\varepsilon} = \lambda_{1,\Omega} + \frac{\omega_{n-1}}{|A|} \varepsilon^{n-1} + o\left(\varepsilon^{n-1}\right)$$

for all $\varepsilon$, where $A = \Omega$ is the eigenset of $\lambda_{1,\Omega}$. Without further assumptions, the upper bound in (0.6) is sharp.
We now consider the case of a regular perturbation of $\Omega$ by diffeomorphisms. We prove the differentiability at 0 of the map $\delta \to \lambda_{1,\Omega_\delta}$ and the convergence of the eigenfunctions without assumptions on the capacity of $K_\delta$. In the case of the $p$-Laplacian, $p > 1$, such type of problems have been considered by Lamberti [15] and Garcia Melian and Sabina De Lis [11]. For $\Omega$ a smooth bounded open subset of $\mathbb{R}^n$, we let $(T_{\delta})_\delta$ be a family of $C^1$-diffeomorphisms of the form

$$T_{\delta}(x) = (1 - \delta \Lambda) x + R(x, \delta),$$

where $x \in \overline{\Omega}$, $\Lambda \in \mathbb{R}$, $\delta \in (-\delta_0, \delta_0)$, $\delta_0 > 0$ is small, and $R(\cdot, \delta) \in C^1(\overline{\Omega}, \mathbb{R}^n)$ is a perturbative term such that $R(x, \delta) = o(\delta)$ and $D_x R(x, \delta) = o(\delta)$ as $\delta \to 0$, uniformly in $x$. In particular, $R(x, 0) = 0$, and if $\Omega_\delta = T_{\delta}(\Omega)$, then $\Omega_0 = \Omega$.

**Theorem 0.3.** Let $\Omega$ be a smooth bounded open subset of $\mathbb{R}^n$, and $\Omega_\delta = T_{\delta}(\Omega)$, where the $T_{\delta}$’s are $C^1$-diffeomorphisms like in (0.3). The function $\delta \to \lambda_{1,\Omega_\delta}$ is continuous and differentiable at $\delta = 0$, and $(\lambda_{1,\Omega_\delta})' (0) = \Lambda \lambda_{1,\Omega}$, where $\Lambda$ is as in (0.8).

In these examples of Theorem 0.3, the 1-capacity of $K_\delta = \text{adh}(\Omega \Delta \Omega_\delta)$ can be large. For instance, if $\Omega = B_0(r)$ and $T_{\delta} = (1 - \delta \Lambda) x$, $\Lambda \neq 0$, then $K_\delta$ is an annulus with inner (or outer, depending on the sign of $\Lambda$) radius $r$. In particular, $\text{cap}_1(K_\delta) = \omega_{n-1} r^{n-1} + o(1)$, and $\text{cap}_1(K_\delta) \neq 0$ as $\delta \to 0$. In other cases, the 1-capacity of $K_\delta$ may tend to zero, and we are back to the situation studied in Theorem 0.1. For instance, if $T_{\delta}(x) = \left(1 + \delta^n R\left(\frac{x}{\delta}\right)\right) x$, $\alpha > 2$, $R \in C^1_0(\mathbb{R}^n)$, and $0 \in \partial \Omega$, then $K_\delta \subset B_0(r_0 \delta)$ for some $r_0 > 0$, and $\text{cap}_1(K_\delta) \to 0$ as $\delta \to 0$. Combining Theorems 0.1 and 0.3, $\Lambda = 0$ if $\text{cap}_1(K_\delta) = o(\delta)$. The following sections are devoted to the proofs of the above theorems.

### 1. Proof of Theorem 0.1

Let $A_\delta$ be an eigenset of $\lambda_{1,\Omega_\delta}$, $\delta > 0$ fixed. Let also $\omega_\delta$ be a smooth bounded open subset such that $K_\delta \subset \omega_\delta$ and

$$\text{cap}_1(K_\delta) \leq |\partial \omega_\delta| \leq \text{cap}_1(K_\delta) + \varepsilon_\delta,$$

where $\varepsilon_\delta > 0$ is such that $\varepsilon_\delta = o(\text{cap}_1(K_\delta))$. We define $v_\delta$ by $v_\delta = \chi_{A_\delta}$ in $\mathbb{R}^n \setminus \omega_\delta$, and $v_\delta = 0$ in $\omega_\delta$. Then $\text{supp} v_\delta \subset \overline{\Omega}$, where $\text{supp} v_\delta$ is the support of $v_\delta$. Since $v_\delta \leq 1$, we can write that

$$\int_{\mathbb{R}^n} |\nabla v_\delta| dx \leq \int_{\mathbb{R}^n} |\nabla \chi_{A_\delta}| dx + |\partial \omega_\delta|$$

$$= |A_\delta| \lambda_{1,\Omega_\delta} + (1 + o(1)) \text{cap}_1(K_\delta),$$

where $o(1) \to 0$ as $\delta \to 0$. We can also write that

$$\int_{\Omega} v_\delta dx = |A_\delta| - \int_{\omega_\delta} \chi_{A_\delta} dx$$

$$= |A_\delta| + O(|\omega_\delta|).$$

By the isoperimetric inequality, and by (1.1), $|\omega_\delta| \leq C|\partial \omega_\delta|^\frac{n-1}{n} = o(\text{cap}_1(K_\delta))$, where $C > 0$ is a dimensional constant independent of $\delta$. Coming back to (L3), it follows that

$$\int_{\Omega} v_\delta dx = |A_\delta| + o(\text{cap}_1(K_\delta)).$$
and by the variational definition of $\lambda_{1,\Omega}$, \cite{12} and \cite{14}, we get that

$$\lambda_{1,\Omega} \leq \lambda_{1,\Omega_\delta} + \frac{1}{|A_\delta|} \text{cap}_1(K_\delta) + \omega(\text{cap}_1(K_\delta)) \quad (1.5)$$

for all $\delta > 0$. Similar arguments give that the converse inequality holds also. We let $A$ be an eigenset for $\lambda_{1,\Omega}$, and let $w_\delta$ be the function given by $w_\delta = \chi_A$ in $\mathbb{R}^n \setminus \overline{\Omega}_\delta$, and $w_\delta = 0$ in $\omega_\delta$, where $\omega_\delta$ is as in \cite{11}. Then $\text{supp}_\delta \subset \overline{\Omega}_\delta$, and, as above, we can write

$$\int_{\mathbb{R}^n} |\nabla w_\delta| dx \leq |A|\lambda_{1,\Omega} + (1 + \omega(1)) \text{cap}_1(K_\delta), \quad \text{and}$$

$$\int_{\Omega_\delta} w_\delta dx = |A| + \omega(\text{cap}_1(K_\delta)). \quad (1.6)$$

In particular, it follows from the variational definition of $\lambda_{1,\Omega_\delta}$ that

$$\lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} + \frac{1}{|A|} \text{cap}_1(K_\delta) + \omega(\text{cap}_1(K_\delta)) \quad (1.7)$$

for all $\delta > 0$. Without loss of generality, by the lower semicontinuity of the total variation, we may choose $A = A_0$ in \cite{17} such that it is of maximum volume among the eigensets for $\lambda_{1,\Omega}$.

In what follows we let $u_\delta \in BV(\Omega_\delta)$ be an eigenfunction for $\lambda_{1,\Omega_\delta}$, like for instance $u_\delta = |A_\delta|^{-1} \chi_{A_\delta}$, and we assume that $\text{cap}_1(K_\delta) \to 0$ as $\delta \to 0$. Then, by \cite{6,11,17}, $\lambda_{1,\Omega_\delta} \to \lambda_{1,\Omega}$ as $\delta \to 0$. Note here that $|A_\delta| \geq C$ for some $C > 0$ (thanks for instance to the Sobolev inequality in $BV(\mathbb{R}^n)$ that we apply to the extensions by zero outside $\overline{\Omega}_\delta$ of the functions $|A_\delta|^{-1} \chi_{A_\delta}$). In what follows we let $D$ be a smooth bounded open subset of $\mathbb{R}^n$ such that $\overline{\Omega} \subset D$, and $\overline{\Omega}_\delta \subset D$ for all $\delta$. We let $\varphi_\delta$ be the extension of $u_\delta$ by zero outside $\overline{\Omega}_\delta$. By \cite{17}, the sequence $(\varphi_\delta)$ is bounded in $BV(D)$. Then, by compactness of the embedding of $BV(D)$ into $L^1(D)$, we may assume that, up to a subsequence, $\varphi_\delta \to \varphi$ in $L^1(D)$ for some $\varphi \in BV(D)$. By the Sobolev inequality for $BV$-functions, we also have that the $\varphi_\delta$'s are bounded in the Lebesgue’s space $L^{n/(n-1)}(D)$. On the one hand, we have that

$$\int_{D \setminus \Omega} |\varphi_\delta| dx \leq ||\varphi_\delta||_{L^{n/(n-1)}} |\Omega_\delta \setminus \Omega|^{1/n} \leq C |\Omega_\delta \setminus \Omega|^{1/n}.$$

On the other hand, we can write with the isoperimetric inequality that

$$|\Omega_\delta \setminus \Omega| \leq |K_\delta| \leq C \text{cap}_1(K_\delta) = o(\text{cap}_1(K_\delta)),$$

where, as above, $C > 0$ is independent of $\delta$. In particular, $\int_{D \setminus \Omega} |\varphi_\delta| dx = o(1)$. We regard $\varphi$ as a function in $\mathbb{R}^n$ (by letting $\varphi = 0$ outside $D$), and let $u = \varphi|\Omega$ be the restriction of $\varphi$ to $\Omega$. Then, according to what we just said, $\varphi = u$ in $\Omega$, and $\varphi = 0$ in $\mathbb{R}^n \setminus \overline{\Omega}$. As is easily checked, $\int_{\Omega} |u| dx = 1$, while by lower semicontinuity of the total variation, and since $\lambda_{1,\Omega_\delta} \to \lambda_{1,\Omega}$, we can write that

$$\lambda_{1,\Omega} = \int_{\mathbb{R}^n} |\nabla u_\delta| dx + o(1) \geq \int_{\mathbb{R}^n} |\nabla \varphi| dx + o(1).$$
In particular, $u$ is an eigenfunction for $\lambda_{1,\Omega}$, and
\[
\lim_{\delta \to 0} \int_{\mathbb{R}^n} |\nabla u_\delta| \, dx = \int_{\mathbb{R}^n} |\nabla u| \, dx.
\] (2.1)
Letting $u_\delta = |A_\delta|^{-1} \chi_{A_\delta}$, we may assume $|A_\delta| \to \Lambda$ for some $\Lambda > 0$, and $u_\delta \to u$ a.e. Since $\int_\Omega |u| \, dx = 1$, we can write that $\pi = |A|^{-1} \chi_A$ for some $A \subset \Omega$. In particular, $A$ is an eigenset for $\lambda_{1,\Omega}$, and $|A_\delta| \to |A|$ so that, by (2.1) and (1.7),
\[
\lambda_{1,\Omega_\delta} = \lambda_{1,\Omega} + \frac{\varepsilon_\delta}{|A_\delta|} \text{cap}_1(K_\delta) + o(\text{cap}_1(K_\delta)),
\]
where $\varepsilon_\delta \in [-1, 1]$ (since $|A| \geq |A_0|$). This is equation (2.6) in Theorem (0.1), and the equation holds for all $\delta$ by contradiction. Noting that the convergence $u_\delta \to u$ in $L^1$ gives that $\chi_{A_\delta} \to \chi_A$ in $L^1$, Theorem (0.1) is proved.

For the remark following Theorem (0.1) there is still to prove that if $\mu_\delta = |\nabla u_\delta|$ and $\mu = |\nabla u|$, then $\mu_\delta \rightharpoonup \mu$ weakly as $\delta \to 0$. By lower semicontinuity of the total variation, $\mu(U) \leq \liminf_{\delta \to 0} \mu_\delta(U)$ for all open subset $U$ of $\mathbb{R}^n$. Conversely, let us assume that there exists a compact subset $K$ of $\mathbb{R}^n$, and $\varepsilon > 0$ such that $\mu(K) + \varepsilon \leq \mu_\delta(K)$ for a subsequence of the $\mu_\delta$'s. Let $\Omega'$ be an open subset of $\mathbb{R}^n$ which contain $\Omega$ and $K$, and the $\Omega'_\delta$'s. Up to passing to another subsequence, by lower semicontinuity of the total variation, we can assume that $\mu(\Omega' \setminus K) \leq \mu_\delta(\Omega' \setminus K) + \varepsilon'$ for all $\delta$, where $\varepsilon' < \varepsilon$ is positive. Then, if $\hat{\varepsilon} = \varepsilon - \varepsilon'$, we can write that
\[
\mu(\mathbb{R}^n) = \mu(\Omega') = \mu(K) + \mu(\Omega' \setminus K)
\]
\[
\leq \mu_\delta(K) - \varepsilon + \mu_\delta(\Omega' \setminus K) + \varepsilon'
\]
\[
= \mu_\delta(\Omega') - \hat{\varepsilon} = \mu_\delta(\mathbb{R}^n) - \hat{\varepsilon}
\]
for all $\delta$, and we get a contradiction with (2.8) since $\hat{\varepsilon} > 0$. As a consequence, for any compact subset $K$ of $\mathbb{R}^n$, $\mu(K) \geq \limsup_{\delta \to 0} \mu_\delta(K)$ and, see for instance Evans-Gariepy [9], we actually proved that the measures $\mu_\delta$ converge weakly to the measure $\mu$.

\section{2. Proof of Theorem (0.2)}

We now turn our attention to the proof of theorem (0.2). As is easily checked from the definition of the 1-capacity, the fact that the 1-capacity is an outer measure, and the isoperimetric inequality in Euclidean space,
\[
\text{cap}_1(K_\delta) = \omega_{n-1} \varepsilon_{\delta,\mu_\delta,\delta}^{-1} + o\left(\varepsilon_{\delta,\mu_\delta,\delta}^{n-1}\right).
\] (2.1)
From independent considerations, we clearly have that $H^1_\delta(\Omega) \subset H^1(\Omega)$. Hence, $\lambda_{1,\Omega} \leq \lambda_{1,\Omega_\delta}$. On the other hand, by the proof of Theorem (0.1), see [17], and by (2.1), we also have that
\[
\lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} + \frac{1}{|A|} \text{cap}_1(K_\delta) + o(\text{cap}_1(K_\delta))
\]
\[
= \lambda_{1,\Omega} + \frac{\omega_{n-1}}{|A|} \varepsilon_{\mu_\delta,\delta}^{n-1} + o\left(\varepsilon_{\delta,\mu_\delta,\delta}^{n-1}\right).
\]
This proves (2.6). It remains to prove (2.7). For this, we need to be more careful than in the proof of Theorem (0.1). We let $A$ be an eigenset for $\lambda_{1,\Omega}$, and let $\omega_\delta$ be the union from $i = 1$ to $k$ of balls $B_{\omega_\delta}(\hat{\varepsilon}_i, \delta)$, $\delta > 0$ small, where $\varepsilon_\delta < \hat{\varepsilon}_i, \delta$, and $\hat{\varepsilon}_i, \delta = (1 + o(1)) \varepsilon_i, \delta$ for all $i$ and $\delta$. For $u = \chi_A$, we let also $u_\delta^i$ be the trace of $u$
when $u$ is restricted to $\mathbb{R}^n \setminus \overline{\omega}_\delta$, and $u^\delta$ be the trace of $u$ when $u$ is restricted to $\omega_\delta$.

Then, $|A|\lambda_{1,\Omega} = \int_{\mathbb{R}^n} |\nabla u| \, dx$, and

$$
\int_{\mathbb{R}^n} |\nabla u| \, dx = \int_{\mathbb{R}^n \setminus \overline{\omega}_\delta} |\nabla u| \, dx + \int_{\omega_\delta} |\nabla u| \, dx + \int_{\partial \omega_\delta} u^+ - u^- \, d\sigma .
$$

(2.2)

In particular, if we let $w_\delta$ be given by $w_\delta = u$ in $\mathbb{R}^n \setminus \overline{\omega}_\delta$, and $w_\delta = 0$ in $\omega_\delta$, we get with (2.2) that

$$
\int_{\mathbb{R}^n} |\nabla w_\delta| \, dx = \int_{\mathbb{R}^n \setminus \overline{\omega}_\delta} |\nabla u| \, dx + \int_{\omega_\delta} u^+ \, d\sigma
\leq |A|\lambda_{1,\Omega} - \int_{\omega_\delta} |\nabla u| \, dx + \int_{\partial \omega_\delta} u^- \, d\sigma
\leq |A|\lambda_{1,\Omega} - \int_{B_\delta} |\nabla u| \, dx + \int_{\partial B_\delta} u^- \, d\sigma + o\left(\varepsilon_{i_0,\delta}^{-1}\right),
$$

(2.3)

where $B_\delta = B_{x_{i_0}}(\varepsilon_{i_0,\delta})$. We also have that

$$
\int_{\partial B_\delta} u^- \, d\sigma = |\partial B_\delta| - \int_{\partial B_\delta} (1 - u^-) \, d\sigma ,
\quad
\int_{B_\delta} |\nabla u| \, dx + \int_{\partial B_\delta} (1 - u^-) \, d\sigma = \int_{\mathbb{R}^n} |\nabla v| \, dx ,
$$

(2.4)

where $v$ is the function $v = \chi_{A^c}$ in $B_\delta$, $v = 0$ in $\mathbb{R}^n \setminus \overline{B}_\delta$, and $A^c = \mathbb{R}^n \setminus A$. If we assume that $x_{i_0} \in \text{int}(\Omega \setminus A)$, then $u^- = 0$ on $\partial B_\delta$, and it follows from the second equation in (1.6) of Section 1 from (2.1) and (2.3), and from the variational definition of $\lambda_{1,\Omega_\delta}$, that the first equation in (0.7) is true. Now we assume that $x_{i_0} \in \partial^* A$. Then, the second equation in (1.6) of Section 1 (2.1), (2.3) - (2.4), and the variational definition of $\lambda_{1,\Omega_\delta}$ give that

$$
\lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} + \frac{1}{|A|} \left( w_{n-1}\varepsilon_{i_0,\delta}^{n-1} - \int_{\mathbb{R}^n} |\nabla v| \, dx \right) + o\left(\varepsilon_{i_0,\delta}^{-1}\right)
$$

(2.5)

for all $\delta$. Let $T_\delta$ be the diffeomorphism given by $T_\delta(x) = x_{i_0} + \varepsilon_{i_0,\delta}^{-1}(x - x_{i_0})$. Then, by the change of variables formula for the total variation, see Giusti [12] or equation (3.1) below, we can write that

$$
\int_{\mathbb{R}^n} |\nabla v| \, dx = \varepsilon_{i_0,\delta}^{-1} \int_{\mathbb{R}^n} |\nabla (v \circ T_\delta^{-1})| \, dx .
$$

(2.6)

Let $A_\delta$ be the set consisting of the $x$ such that $T_\delta^{-1}(x) \in A^c$. Then $v \circ T_\delta^{-1} = \chi_{A_\delta}$ in $B$, and $v \circ T_\delta^{-1} = 0$ in $\mathbb{R}^n \setminus \overline{B}$, where $B = B_{x_{i_0}}(1)$. Since $\partial^* A^c = \partial^* A$, $x_{i_0} \in \partial^* A^c$. By the blow-up property of the reduced boundary (see, for instance, Evans-Gariepy [9]), we can write that

$$
\chi_{A_\delta} \rightarrow \chi_{H^-(x_{i_0})} \quad \text{in} \quad L^1_{\text{loc}}(\mathbb{R}^n)
$$

(2.7)

as $\delta \rightarrow 0$, where $H^-(x_{i_0})$ consists of the $y \in \mathbb{R}^n$ such that $\nu_{A^c}(x_{i_0})(y-x_{i_0}) \leq 0$, and where $\nu_{A^c}(x_{i_0})$ is the generalized exterior normal to $A^c$ at $x_{i_0}$. By (2.1), $v \circ T_\delta^{-1} \rightarrow \hat{v}$ in $L^1(\mathbb{R}^n)$, where $\hat{v} = \chi_{H^-(x_{i_0})}$ in $B$, and $\hat{v} = 0$ in $\mathbb{R}^n \setminus \overline{B}$. By lower semicontinuity of the total variation, it follows that

$$
\int_{\mathbb{R}^n} |\nabla (v \circ T_\delta^{-1})| \, dx \geq \int_{\mathbb{R}^n} |\nabla \hat{v}| \, dx + o(1) ,
$$

(2.8)
while we easily check that
\[
\int_{\mathbb{R}^n} |\nabla \hat{v}| \, dx = \frac{1}{2} \omega_{n-1} + b_{n-1},
\]
where \( b_n \) is the volume of the unit ball in \( \mathbb{R}^n \). Combining (2.5)–(2.9), we get that the second equation in (0.7) is also true. This ends the proof of Theorem 0.2.

The proof of Theorem 0.2, and hence the theorem itself, easily extend to other, more general, types of holes. For instance, when we do not assume anymore that only one of the \( \varepsilon_{i,\delta} \) is leading, or when we subtract \( K_{i,\delta} \subset B_{x_i}(\varepsilon_{i,\delta}) \) instead of the whole ball. Only slight modifications in the proof, that we leave to the reader, are required to get such extensions.

3. PROOF OF THEOREM 0.3

By the change of variables formula for the total variation (see Giusti [12]), if \( T \) is a \( C^1 \)-diffeomorphism from \( \mathbb{R}^n \) to \( \mathbb{R}^n \), \( \Omega \) is a smooth open subset of \( \mathbb{R}^n \), and \( u \in BV(\Omega) \), then
\[
\int_{\Omega^*} |\nabla u^*| \, dx = \int_{\Omega} |(DT)^{-1}\nu_u||DT||\nabla u| \, dx,
\]
where \( \Omega^* = T(\Omega) \), \( u^* = u \circ T^{-1} \), \( \nu_u \) is the Radon-Nikodym derivative of \( \nabla u \) with respect to \( |\nabla u| \), and \( |DT| \) is the absolute value of the determinant of \( DT \). By (3.1) with \( T = T_\delta \), noting that \( |\nu_u| = 1 \) for \( |\nabla u| \)-almost all \( x \), by the variational definition of \( \lambda_{1,\Omega_\delta} \), and by (0.8), we easily get that \( \limsup_{\delta \to 0} \lambda_{1,\Omega_\delta} \leq \lambda_{1,\Omega} \). Conversely, we let \( u_\delta \) be a nonnegative eigenfunction for \( \lambda_{1,\Omega_\delta} \), and we define the function \( v_\delta \) by \( v_\delta = u_\delta \circ T_\delta \). By (1.8), (3.1), and what we just said, the sequence \( (v_\delta) \) is bounded in \( BV(\mathbb{R}^n) \), with the additional properties that
\[
\int_{\mathbb{R}^n} |\nabla v_\delta| \, dx \leq (1 + o(1)) \lambda_{1,\Omega_\delta}, \quad \text{and}
\int_{\Omega} v_\delta \, dx = (1 + o(1)) \int_{\Omega_\delta} u_\delta \, dx = 1 + o(1),
\]
where \( o(1) \to 0 \) as \( \delta \to 0 \). As above, we adopt the notation \( v_\delta \) for the extension of \( v_\delta \) by zero outside \( \Omega \). Let \( D \) be a bounded domain in \( \mathbb{R}^n \) which contain both \( \Omega \) and the \( \Omega_\delta \)'s. By compactness of the embedding of \( BV(D) \) into \( L^1(D) \), we may assume that, up to a subsequence, \( v_\delta \to v \) in \( L^1(D) \) and almost everywhere as \( \delta \to 0 \). Let \( u \) be the restriction of \( v \) to \( \Omega \). Then \( u \geq 0 \) and, by the second equation in (3.2), \( \int_{\Omega} u \, dx = 1 \). Moreover, by the first equation in (3.2), and by lower semicontinuity of the total variation,
\[
\lambda_{1,\Omega} \leq \int_{\mathbb{R}^n} |\nabla \overline{u}| \, dx
\leq \int_D |\nabla v| \, dx \leq \liminf_{\delta \to 0} \lambda_{1,\Omega_\delta},
\]
where \( \overline{u} \) stands for the extension of \( u \) by zero outside \( \Omega \). In particular, \( \lambda_{1,\Omega_\delta} \to \lambda_{1,\Omega} \) as \( \delta \to 0 \), and the function \( \delta \to \lambda_{1,\Omega_\delta} \) is continuous at \( \delta = 0 \). This proves the first assertion in Theorem 0.3.
As a consequence of the above developments,

$$\int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx \to \int_{\mathbb{R}^n} |\nabla \varphi| dx$$

as $\delta \to 0$, and $u$ is an eigenfunction for $\lambda_{1,\Omega}$. In particular, like in Section 11, $\mu_\delta \to \mu$ weakly, where $\mu_\delta = |\nabla \varphi_\delta|$ and $\mu = |\nabla \varphi|$. In what follows we let $A_\delta$ be an eigenset for $\lambda_{1,\Omega_\delta}$ and let $u_\delta = |A_\delta|^{-1} \chi_{A_\delta}$. Then (we refer again to Section 11 for the simple argument involved here), $\varphi = |A|^{-1} \chi_A$, where $A$ is an eigenset for $\lambda_{1,\Omega}$. In particular, $|\nabla \varphi_\delta| \to \mu$ weakly, and $\mu = |A|^{-1} |\partial_\ast A|$, where $\partial_\ast A$ is the measure theoretic boundary of $A$ (see for instance Evans-Gariepy [2]), and $\mathcal{H}^{n-1}$ is the $(n-1)$-dimensional Hausdorff measure. Now we prove the second assertion in Theorem 0.3, namely the differentiability of the eigenvalue $\lambda_{1,\Omega_\delta}$ at $\delta = 0$ and the equation $(\lambda_{1,\Omega_\delta})' (0) = \Lambda \lambda_{1,\Omega}$. As is easily checked from (3.8), for any $x \in \Omega$, and any $X \in \mathbb{R}^n$ such that $|X| = 1$,

$$|DT_\delta (x)| = 1 - n \Lambda \delta + o(\delta) , \quad \text{and}$$

$$|(DT_\delta) (x)^{-1} X| = 1 + \Lambda |X|^2 \delta + o(\delta) ,$$

where the $o(\delta)$’s are uniform in $x$ and $X$. By (3.2) and (3.1), with $T = T_\delta$, we can write that

$$\lambda_{1,\Omega_\delta} \leq \frac{\int_{\mathbb{R}^n} |(DT_\delta)^{-1} \nu u| |DT_\delta| |\nabla \varphi| dx}{\int_{\mathbb{R}^n} |DT_\delta| u dx} ,$$

where $u$ and $\varphi$ are as above. By (3.3),

$$\int_{\Omega} |DT_\delta| u dx = 1 - n \Lambda \delta + o(\delta) .$$

Since $|\nu_u| = 1$ a.e w.r.t $\mu$, and $\mathcal{H}^{n-1} (\partial_\ast A \setminus \partial_\ast A) = 0$, we also get with (3.3) that

$$\frac{1}{\lambda_{1,\Omega}} \int_{\mathbb{R}^n} |(DT_\delta)^{-1} \nu u| |DT_\delta| |\nabla \varphi| dx = 1 - (n-1) \Lambda \delta + o(\delta) .$$

Plugging (3.5) and (3.6) into (3.4), it follows that

$$\lambda_{1,\Omega_\delta} - \lambda_{1,\Omega} \leq \Lambda \delta \lambda_{1,\Omega} + o(\delta) .$$

In order to get the converse inequality, we write, still using (3.2) and (3.1), that

$$\lambda_{1,\Omega_\delta} - \lambda_{1,\Omega} \geq \frac{\int_{\mathbb{R}^n} |(DT_\delta)^{-1} \nu \delta| |DT_\delta| |\nabla \varphi_\delta| dx}{\int_{\mathbb{R}^n} |DT_\delta| v dx} - \int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx ,$$

where $\nu_\delta$ is the Radon-Nikodym derivative of $\nabla \varphi_\delta$ with respect to $|\nabla \varphi_\delta|$. By (3.8), since $|\nu_\delta| = 1$ for $\mu_\delta$-almost all points,

$$\int_{\mathbb{R}^n} |(DT_\delta)^{-1} \nu \delta| |DT_\delta| |\nabla \varphi_\delta| dx = \int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx -(n-1) \Lambda \delta \int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx + o(\delta)$$

and

$$\int_{\Omega} |DT_\delta| v dx = \int_{\Omega} v dx - n \Lambda \delta \int_{\Omega} v dx + o(\delta) .$$

Combining (3.8), (3.9), and (3.10), it follows that

$$\lambda_{1,\Omega_\delta} - \lambda_{1,\Omega} \geq \frac{\int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx}{\int_{\Omega} v dx} \Lambda \delta + o(\delta) .$$

Since $\int_{\Omega} v dx \to 1$ and $\int_{\mathbb{R}^n} |\nabla \varphi_\delta| dx \to \lambda_{1,\Omega}$ as $\delta \to 0$, it follows from (3.7) and (3.11) that $\lambda_{1,\Omega_\delta} - \lambda_{1,\Omega} = \Lambda \delta \lambda_{1,\Omega} + o(\delta)$. The equation holds for a subsequence,
but since the right hand side in the equation does not depend on the subsequence, it holds true for all $\delta$. In particular, $(\lambda_{1,\Omega})'(0) = \Lambda \lambda_{1,\Omega}$ and this ends the proof of Theorem 0.3.

The proof of the first assertion in Theorem 0.3 and hence the continuity of $\lambda_{1,\Omega_\delta}$ at $\delta = 0$, extend to very general $T_\delta$'s. We basically only need that $T_\delta \to \text{Id}$ in the $C^1$-topology as $\delta \to 0$.
