Abstract: We analyze the constraints on a CP-violating, flavor conserving, two Higgs doublet model from the measurements of Higgs properties and from the search for heavy Higgs bosons at LHC, and show that the stronger limits typically come from the heavy Higgs search channels. The limits on CP violation arising from the Higgs sector measurements are complementary to those from EDM measurements. Combining all current constraints from low energy to colliders, we set generic upper bounds on the CP violating angle which parametrizes the CP odd component in the 126 GeV Higgs boson.
1 Introduction

Now that the 126 GeV Higgs boson has been discovered [1, 2], the exploration of its properties is the focus of LHC phenomenology. The current measurements of Higgs production and decay rates are consistent with the Standard Model (SM) predictions at the $\sim 10-20\%$ level, leaving open the possibility that there is additional physics in the Higgs sector. One attractive alternative to the SM is the two Higgs doublet model (2HDM), which has 5 Higgs bosons, allowing for new phenomena in the Higgs sector [3]. The couplings of the Higgs bosons to fermions and gauge bosons in the CP conserving 2HDM depend on 2 parameters: $\alpha$, which
describes the mixing in the neutral Higgs boson sector, and $\tan \beta$, the ratio of Higgs vacuum expectation values. Measurements of Higgs coupling properties in the CP conserving limit require that the 2HDM be close to the alignment limit, $\beta - \alpha \sim \frac{\pi}{2}$ [4–7].

The SM explains CP violation through the CKM mixing matrix, which is sufficient to account for observed CP violation in the $B$ and $K$ systems. However, it is insufficient to explain the excess of matter over anti-matter in the universe, suggesting that there may be further sources of CP violation [8, 9]. The 2HDM offers the possibility for a new source of CP violation beyond the CKM matrix and QCD $\theta$ term. In such a scenario, the 126 GeV Higgs boson can be a mixture of CP even and CP odd states [10–14]. The LHC data has already excluded the case that the 126 Higgs is a pure CP odd scalar [15, 16], but the constraints on its CP odd mixture are still rather weak. There have been proposals of new techniques to directly measure the Higgs CP mixture in future colliders [17–24]. The parameters of the CP violating version of the 2HDM receive complementary limits from LHC Higgs coupling measurements and from low energy measurements such as electric dipole moments (EDMs). The measurements of Higgs couplings do not put a strong constraint on the CP violating phase, especially in the alignment limit [10], and the strongest limits come from EDMs [8, 10, 11, 25–27].

CP violation in the Higgs sector has been studied extensively in the MSSM limit of the 2HDM [28, 29]. The MSSM contains many sources of CP violation from the soft SUSY breaking terms in the effective Lagrangian [30]. The primary restriction on this type of CP violation arises from the requirement that the lightest Higgs boson have a mass near 126 GeV [31]. Analogous limits to those obtained in this work from Higgs couplings, heavy Higgs searches, and EDMS can be found in the MSSM [32].

We consider a CP violating 2HDM scenario which has a softly broken $Z_2$ symmetry which avoids large flavor changing neutral currents from Higgs exchange, but allows for new CP violation from the scalar potential. We further allow the Higgs couplings to have small deviations from the alignment limit. In this work, we consider the additional constraints on the parameters of the theory arising from the search for heavy Higgs bosons. In the CP conserving 2HDM, the search for heavy Higgs bosons significantly restricts the allowed parameter space for small $\tan \beta$ [33, 34] and this remains true in the CP violating case. In the context of the 2HDMs, if there is significant CP violation, the heavy Higgs boson masses cannot be too heavy and in some regions of parameter space the LHC heavy Higgs searches can place the leading constraint on CP violation.

In Section 2, we review the CP violating 2HDM and predictions for Higgs boson production and decay within this class of models. Limits from heavy Higgs searches are discussed in Section 3 and compared with low energy limits from the electron EDM. We have also updated the results of Refs. [10, 35–37] for the limits on the CP violating parameters from Higgs coupling fits. Finally, Section 5 contains a concluding discussion of the complementary limits on CP violating 2HDMs from Higgs coupling fits, heavy Higgs searches, EDMs, the oblique parameters, and $g - 2$. 
2 Two Higgs Doublet Models and CP Violation

In this section we review the 2HDMs considered in this study.

2.1 Scalar Potential with Two Higgs Doublets

The most general two Higgs doublet potential which breaks $SU(2)_L \times U(1)$ to $U(1)_{EM}$ is,

$$
V(\phi_1, \phi_2) = -\frac{1}{2} \left[ m_{11}^2 (\phi_1^\dagger \phi_1) + \left( m_{12}^2 (\phi_1^\dagger \phi_2) + \text{h.c.} \right) + m_{22}^2 (\phi_2^\dagger \phi_2) \right] 
+ \frac{\lambda_1}{2} (\phi_1^\dagger \phi_1)^2 
+ \frac{\lambda_2}{2} (\phi_2^\dagger \phi_2)^2 
+ \lambda_3 (\phi_1^\dagger \phi_1)(\phi_2^\dagger \phi_2) 
+ \lambda_4 (\phi_1^\dagger \phi_2)(\phi_2^\dagger \phi_1) 
+ \frac{1}{2} \left[ \lambda_5 (\phi_1^\dagger \phi_1)^2 + \lambda_6 (\phi_1^\dagger \phi_2)(\phi_1^\dagger \phi_1) + \lambda_7 (\phi_1^\dagger \phi_2)(\phi_2^\dagger \phi_2) + \text{h.c.} \right] .
$$

The potential of Eq. (2.1) leads to tree level flavor changing neutral currents, which can be avoided by imposing a $Z_2$ symmetry under which,

$$
\phi_1 \rightarrow -\phi_1 \quad \phi_2 \rightarrow \phi_2.
$$

Eq. (2.2) implies $\lambda_6 = \lambda_7 = 0$, while a non-zero $m_{12}$ softly breaks the $Z_2$ symmetry of Eq. (2.2).

After electroweak symmetry breaking, the Higgs doublets in unitary gauge can be written as,

$$
\phi_1 = \begin{pmatrix} -\sin \beta H^+ \\ \frac{1}{\sqrt{2}} (v \cos \beta + H^0) \end{pmatrix} , \quad \phi_2 = e^{i\xi} \begin{pmatrix} \cos \beta H^+ \\ \frac{1}{\sqrt{2}} (v \sin \beta + H^0) \end{pmatrix} , \quad (2.3)
$$

where $\tan \beta = v_2/v_1$, $v = \sqrt{|v_1|^2 + |v_2|^2} = 246$ GeV and $H^+$ is the physical charged Higgs with mass $m_{H^+}$. We are free to redefine fields and go to a basis where $\xi = 0$. In general there are 2 independent phases and the imaginary parts of $m_{12}$ and $\lambda_5$ lead to mixing in the neutral Higgs sector between $H^0_1, H^0_2$ and $A^0$, and that is the source of CP violation.

The mixing among the three neutral scalars can be parametrized by an orthogonal matrix $R$,

$$
R = \begin{pmatrix} -s_\alpha c_\beta b & c_\alpha c_\beta b & s_\alpha b \\ s_\alpha s_\beta b c_\alpha - c_\alpha c_\beta s_\alpha - c_\alpha s_\beta s_\alpha c_\alpha s_\alpha c & c_\alpha s_\beta b c_\alpha - c_\alpha c_\beta s_\alpha - c_\alpha s_\beta s_\alpha c_\alpha s_\alpha c & s_\alpha b \\ s_\alpha s_\beta b c_\alpha + c_\alpha s_\beta c_\alpha - c_\alpha s_\beta c_\alpha c_\alpha s_\alpha c & c_\alpha s_\beta b c_\alpha + c_\alpha c_\beta s_\alpha - c_\alpha s_\beta s_\alpha c_\alpha s_\alpha c & c_\alpha b \end{pmatrix} ,
$$

where $s_\alpha = \sin \alpha$, etc and

$$
-\frac{\pi}{2} < \alpha_b \leq \frac{\pi}{2} \quad -\frac{\pi}{2} \leq \alpha_c \leq \frac{\pi}{2} .
$$

The physical mass eigenstates are then defined as $(h_1, h_2, h_3)^T = R(H^0_1, H^0_2, A^0)^T$. In the CP conserving version of the 2HDM, $\alpha_b = \alpha_c = 0$, $R$ is block diagonal, and $h_1$ and $h_2$ have no pseudoscalar component.
2.2 Neutral Scalar Interactions

For simplicity, we focus on the 2HDMs where the Yukawa sector has a $Z_2$ symmetry and $\phi_1$ and $\phi_2$ each only gives mass to up or down type fermions. This is sufficient to suppress tree-level flavor changing processes mediated by the neutral Higgs scalars. For the 3rd generation (and suppressing CKM mixing),

$$
\mathcal{L} = \begin{cases}
- \left( \frac{\cos \alpha m_t}{\sin \beta v} \right) Q_L (i \tau_2) \phi_2^* t_R - \left( \frac{\cos \alpha m_b}{\sin \beta v} \right) Q_L \phi_2 b_R + \text{h.c.} & \text{Type I} \\
- \left( \frac{\cos \alpha m_t}{\sin \beta v} \right) Q_L (i \tau_2) \phi_2^* t_R + \left( \frac{\sin \alpha m_b}{\cos \beta v} \right) Q_L \phi_2 b_R + \text{h.c.} & \text{Type II},
\end{cases}
$$

where $Q_L^T = (t_L, b_L)$. In both cases, we assume that the charged lepton Yukawa coupling has the same form as that of the charge $-1/3$ quarks. Under the $Z_2$ symmetry, $Q_L, t_R, \phi_2$ are always even, $\phi_1$ is always odd, and $b_R$ is even (odd) in Type I (II) models.

From this we can derive the couplings between neutral Higgs bosons and the fermions and gauge bosons. As a general parametrization we take,

$$
\mathcal{L} = \sum_{i=1}^{3} \left[ -m_f \left( c_{f,i} \bar{f} f + \tilde{c}_{f,i} \bar{f} i\gamma_5 f \right) \frac{h_i}{v} + \left( 2a_i M_W^2 W_i W^\mu + a_i M_Z^2 Z_i Z^\mu \right) \frac{h_i}{v} \right].
$$

When $c_{f,i}, \tilde{c}_{f,i} \neq 0$ or $a_i, \tilde{c}_{f,i} \neq 0$, the mass eigenstate $h_i$ couples to both CP even and CP odd operators, so the theory violates CP. The coefficients $c_{f,i}, \tilde{c}_{f,i}$ and $a_i$ can be derived from $\tan \beta$ and the elements of the matrix $R$ defined above. An appealing feature is that all couplings

| Type  | $c_{t,i}$ | $c_{b,i} = c_{\tau,i}$ | $\tilde{c}_{t,i}$ | $\tilde{c}_{b,i} = \tilde{c}_{\tau,i}$ | $a_i$ |
|-------|-----------|------------------------|-------------------|-------------------------|-------|
| Type I | $R_{12}/\sin \beta$ | $R_{12}/\sin \beta$ | $-R_{13} \cot \beta$ | $R_{13} \cot \beta$ | $R_{12} \sin \beta + R_{11} \cos \beta$ |
| Type II | $R_{12}/\sin \beta$ | $R_{11}/\cos \beta$ | $-R_{13} \cot \beta$ | $-R_{13} \tan \beta$ | $R_{12} \sin \beta + R_{11} \cos \beta$ |

Table 1. Fermion and gauge boson couplings to Higgs mass eigenstates.

in Table 1 depend on only four parameters, $\alpha, \alpha_b, \alpha_c$ and $\tan \beta$. It is worth noting that the couplings of the light Higgs boson $h_1$ to the gauge bosons and fermions are independent of $\alpha_c$. Fits to the CP conserving 2HDM suggest that the couplings are close to the alignment limit, $\beta - \alpha \sim \frac{\pi}{2}$, implying that $h_1$ has couplings very close to the SM predictions. In our numerical studies, we will allow small deviations from the alignment limit.

2.3 CP Violation Implies a Non-Decoupled Heavy Higgs Sector

In general, the imposed $Z_2$ symmetry in the Yukawa sector is not preserved by renormalization. The hard breaking $\lambda_6, \lambda_7$ terms from the Higgs potential will induce couplings of $\phi_1, \phi_2$ to both up and down type quarks. This does not reintroduce any tree level flavor changing effects because the induced Yukawa matrices are still aligned with the corresponding fermion mass matrices. Motivated by this, a convenient choice is to forbid the $\lambda_6, \lambda_7$ terms. In this
case, the model has an approximate $Z_2$ symmetry, which is only softly broken by the $m_{12}^2$ term.

For the approximate $Z_2$ symmetric model, all of the potential parameters can be solved for in terms of the following parameters:

- The scalar masses, $m_{h_1}$, $m_{h_2}$, $m_{h_3}$ and $m_{H^\pm}$
- The neutral scalar mixing angles, $\alpha$, $\alpha_b$, $\alpha_c$
- The ratio of vev’s, $\tan \beta$
- One potential parameter, $\text{Re}(m_{12}^2)$, or $\nu \equiv \text{Re}(m_{12}^2)/(v^2 \sin 2\beta)$

The explicit solution for the parameters of the scalar potential was found in Ref. [10], and is listed below in Appendix A. The imaginary part of $\lambda_5$, which is a source of CP violation, is given in the alignment limit by,

$$\text{Im}\lambda_5 = 2 \cos \alpha_b \frac{v^2 \sin \beta}{2} \left[ (m_{h_2}^2 - m_{h_3}^2) \cos \alpha \sin \alpha_c \cos \alpha_c 
+ (m_{h_1}^2 - m_{h_2}^2 \sin^2 \alpha_c - m_{h_3}^2 \cos^2 \alpha_c) \sin \alpha \sin \alpha_b \right]. \quad (2.8)$$

Clearly, when the scalars $h_{2,3}$ are much heavier than the electroweak scale, and $m_{h_2} \simeq m_{h_3} \equiv m_{H^\pm} \gg m_{h_1}$, one has

$$| \sin 2\alpha_b | \simeq \frac{| \text{Im}\lambda_5 | v^2 \tan \beta}{m_{H^\pm}^2} \cdot (2.9)$$

The unitarity bound on $\text{Im}\lambda_5$, $\text{Im}\lambda_5 < 4\pi$, sets the largest allowed CP violating mixing angle $\alpha_b$. This implies that for an $\mathcal{O}(1)$ $\sin \alpha_b$ to be theoretically accessible, the heavy scalars $h_2$, $h_3$ and $H^\pm$ must be not far above the electroweak scale. In general, for nonzero $\alpha_b$, the masses of the heavy scalars should satisfy

$$m_{H^\pm} \lesssim 870 \text{ GeV} \times \sqrt{| \text{Im}\lambda_5 | \sqrt{\tan \beta} \sin 2\alpha_b} \cdot (2.10)$$

A similar conclusion holds when one goes beyond the approximate $Z_2$ symmetry by including the $\lambda_6, \lambda_7$ terms.

### 2.4 Beyond Approximate $Z_2$ Symmetry

For the approximate $Z_2$ symmetric model, there is a further theoretical constraint on the physical parameters resulting from the minimization of the potential. This constraint is given in Eq. (A.10) and can be transformed into a quadratic equation for $\tan \alpha_c$. The condition for $\alpha_c$ to have a real solution is

$$\sin^2 \alpha_b \leq \frac{(m_{h_3}^2 - m_{h_2}^2) \cot^2(\alpha + \beta)}{4(m_{h_2}^2 - m_{h_1}^2)(m_{h_3}^2 - m_{h_1}^2)} \equiv \sin^2 \alpha_b^{\text{max}} \cdot (2.11)$$
When Eq. (2.11) is satisfied, the solutions for $\alpha_c$ are,

$$
\alpha_c = \begin{cases} 
\alpha_c^-, & \alpha + \beta \leq 0 \\
\alpha_c^+, & \alpha + \beta > 0 
\end{cases},
$$

$$
\tan \alpha_c^\pm = \frac{\pm |\sin \alpha_b^{\text{max}}| \pm \sqrt{\sin^2 \alpha_b^{\text{max}} - \sin^2 \alpha_b}}{\sin \alpha_b} \sqrt{m_{h_2}^2 - m_{h_1}^2}. 
$$

(2.12)

Eq. (2.11) implies an additional theoretical upper bound on the CP violating angle $\alpha_b$, when the other parameters are fixed. In practice, we sometimes find this bound can be stronger than all the experimental limits. However, this is only a bound because of theoretical prejudice. In fact, it can be removed with a minimal step beyond the approximate $Z_2$ symmetric case by introducing a $\lambda_7$ term, with $\lambda_7$ being purely imaginary. In this case, the bound Eq. (2.11) no longer exists, $\alpha_c$ becomes a free parameter, and $\text{Im} \lambda_7$ can in turn be solved for as,

$$
\text{Im} \lambda_7 = \frac{2 \cos \alpha_b}{v^2 \tan^2 \beta} \left[ (m_{h_3}^2 - m_{h_2}^2) \sin \alpha_c \cos \alpha_c \frac{\cos(\alpha + \beta)}{\cos^2 \beta} + (m_{h_2}^2 \sin^2 \alpha_c + m_{h_3}^2 \cos^2 \alpha_c - m_{h_1}^2) \sin \alpha_b \frac{\sin(\alpha + \beta)}{\cos^2 \beta} \right]. 
$$

(2.13)

Although introducing hard $Z_2$ breaking ($\lambda_{6,7} \neq 0$) makes the Yukawa structure in Eq. (2.6) unnatural, one might argue it is accidentally the case at the electroweak scale. In the phenomenological study in the next section, we will give the results for both the approximate $Z_2$ case, and the minimal extension as discussed in this subsection.

### 2.5 Production and Decay of the Heavy Higgs at LHC

#### 2.5.1 Production

The dominant heavy Higgs boson production channels relevant to this study are gluon fusion, $gg \rightarrow h_{2,3}$, vector boson fusion, $qq \rightarrow qqh_{2,3}$, and production in association with bottom quarks, $gg/q\bar{q} \rightarrow h_{2,3}b\bar{b}$. In the 2HDM we explore, the interactions between the heavy neutral Higgs bosons and the SM fermions and the $W,Z$ gauge bosons are simply rescaled from those of a SM-like Higgs boson, $H_{SM}$, by a factor given in Table 1. Therefore, it is convenient to take the SM-like Higgs cross sections, and rescale them with these factors and the appropriate form factors. The LHC production cross sections for a heavy SM-like Higgs boson have been calculated by the LHC Higgs Cross Section Working Group and given in [41, 42].

For the gluon fusion process, we calculate the ratio of the heavy Higgs boson production cross section in a CP violating 2HDM to that of a SM-like Higgs with the same mass. At

\[1\] We are aware that allowing $Z_2$ breaking terms in the Yukawa sector can introduce additional sources of CP violation. The price for this is introducing tree level flavor changing effects at the same time, and some flavor alignment mechanism must be resorted to [38–40]. We do not consider such a possibility, but focus on CP violation only from the Higgs sector in this work.
one-loop,

\[ R_{gg}^i = \frac{\sigma(gg \to h_i)}{\sigma(gg \to H_{SM})} = \frac{|c_{t,i}A_{1/2}^H(\tau_i^t) + c_{b,i}A_{1/2}^H(\tau_i^b)|^2 + |\tilde{c}_{t,i}A_{1/2}^A(\tau_i^t) + \tilde{c}_{b,i}A_{1/2}^A(\tau_i^b)|^2}{|A_{1/2}^H(\tau_i^t) + A_{1/2}^H(\tau_i^b)|^2} \tag{2.14} \]

where \( \tau_i^f = m_{h_i}^2/(4m_f^2) \) and \( i = 1, 2, 3, f = t, b \). The form factors \( A_{1/2}^H, A_{1/2}^A \) are given by

\[ A_{1/2}^H(\tau) = 2(\tau + (\tau - 1)f(\tau))\tau^{-2}, \tag{2.15} \]
\[ A_{1/2}^A(\tau) = 2f(\tau)\tau^{-1}, \tag{2.16} \]

\[ f(\tau) = \begin{cases} \arcsin^2(\sqrt{\tau}), & \tau \leq 1 \\ \frac{1}{4} \log \left( \frac{1+\sqrt{1-\tau}}{1-\sqrt{1-\tau}} \right) - i\pi \end{cases}^2, \quad \tau > 1. \tag{2.17} \]

For vector boson fusion, the ratio of the heavy Higgs production cross section in a 2HDM to that of a SM-like Higgs with the same mass is simply

\[ R_{VBF}^i = \frac{\sigma(qq \to qqh_i)}{\sigma(qq \to qqH_{SM})} = (a_i)^2. \tag{2.18} \]

For \( h_{2,3}bb \) associated production, we take the NLO cross section for SM-like Higgs boson production in the 4 flavor number scheme from Ref. [43, 44]. There the cross section contains two pieces, one is proportional to \( y_b^2 \), and the other proportional to \( y_b y_t \) from interference. We rescale these results with the heavy Higgs-fermion couplings in a 2HDM,

\[ \sigma(bb \to h_i) = (c_{b,i})^2 \sigma_b^H(m_{h_i}) + c_{t,i}c_{b,i} \sigma_t^H(m_{h_i}) + (\tilde{c}_{b,i})^2 \sigma_b^A(m_{h_i}) + \tilde{c}_{t,i}\tilde{c}_{b,i} \sigma_t^A(m_{h_i}), \tag{2.19} \]

where \( \sigma_b^H \) is the cross section for \( gg \to bbh_i \) where the Higgs couples to the \( b \) quarks, \( \sigma_t^H \) is the interference between diagrams contributing to \( gg \to bbh_i \) where the Higgs couples to the \( b \) and the \( t \) quark. \( \sigma_b^A \) and \( \sigma_t^A \) are the corresponding contributions from the pseudoscalar couplings to the \( b \) and \( t \) quarks given in Eq. (2.7).

### 2.5.2 Decays

The heavy neutral scalar to electroweak gauge boson decay rates are

\[ \Gamma(h_i \to VV) = (a_i)^2 \frac{G_F m_{h_i}^3}{16\sqrt{2}\pi} \delta_V \left( 1 - \frac{4M_V^2}{m_{h_i}^2} \right)^{1/2} \left[ 1 - \frac{4M_V^2}{m_{h_i}^2} + \frac{3}{4} \left( \frac{4M_V^2}{m_{h_i}^2} \right)^2 \right], \tag{2.20} \]

where \( V = W, Z \) and \( \delta_W = 2, \delta_Z = 1 \), and \( i = 2, 3 \). The decay rates to SM fermions are

\[ \Gamma(h_i \to ff) = \left[ (c_{f,i})^2 + (\tilde{c}_{f,i})^2 \right] \frac{N_c G_F m_{h_i}^3}{4\sqrt{2}\pi} \left( 1 - \frac{4m_f^2}{m_{h_i}^2} \right)^{3/2}, \tag{2.21} \]

where \( N_c = 3 \) for quarks and 1 for charged leptons.
The heavy scalars can also decay to a pair of gluons via a loop of top or bottom quarks, and the rates are
\[
\Gamma(h_i \rightarrow gg) = \frac{\alpha_s^2 G_F \frac{m_{h_i}^3}{4\sqrt{2}\pi^3}}{h_i^3} \left[ c_{t,i} A_{1/2}^H (\tau_{t,i}^1) + c_{b,i} A_{1/2}^H (\tau_{b,i}^1) \right]^2 + \left[ c_{t,i} A_{1/2}^A (\tau_{t,i}^1) + c_{b,i} A_{1/2}^A (\tau_{b,i}^1) \right]^2. \tag{2.22}
\]
Clearly a decay rate is a CP even quantity. Thus, in all the above decay rates, the CP even coefficient \(c_f^H\) and the CP odd one \(c_f^A\) always contribute incoherently.

In our study, we are also interested in the heavy neutral scalars, \(h_2, h_3\), decaying into the \(Z\) boson and the 126 GeV Higgs boson,
\[
\Gamma(h_i \rightarrow Zh_1) = \frac{|g_{i,1}|^2}{16\pi m_{h_i}^2} \sqrt{\left( m_{h_i}^2 - (m_{h_1} + M_Z)^2 \right) \left( m_{h_i}^2 - (m_{h_1} - M_Z)^2 \right)} \times \left[ -2m_{h_1}^2 + 2m_{h_i}^2 - M_Z^2 \right] + \frac{1}{M_Z^2} \left[ m_{h_i}^2 - m_{h_1}^2 \right]^2, \tag{2.23}
\]
where \(g_{i,1} = (e/\sin 2\theta_W) [(-\sin \beta R_{11} + \cos \beta R_{12}) R_{i3} - (-\sin \beta R_{11} + \cos \beta R_{12}) R_{i3}].\)

We have also calculated the decay rate of \(h_i \rightarrow 2h_1\) from the Higgs self-interactions. The decay rate is
\[
\Gamma(h_i \rightarrow h_1 h_1) = \frac{g_{i,11}^2 v^2}{2\pi m_{h_i}^2} \sqrt{1 - \frac{4m_{h_1}^2}{m_{h_i}^2}}, \tag{2.24}
\]
where \(g_{i,11}, (i = 2, 3)\) are defined in Appendix B.

To get the branching ratios, we calculate the total width of the heavy Higgs\(^2\),
\[
\Gamma_{tot}(h_i) = \Gamma(h_i \rightarrow W^+W^-) + \Gamma(h_i \rightarrow ZZ) + \Gamma(h_i \rightarrow t\bar{t}) + \Gamma(h_i \rightarrow b\bar{b}) + \Gamma(h_i \rightarrow \tau^+\tau^-) + \Gamma(h_i \rightarrow gg) + \Gamma(h_i \rightarrow Zh_1) + \Gamma(h_i \rightarrow h_1 h_1). \tag{2.25}
\]
Finally, for each channel, the ratio of signal strengths in the 2HDM to the counterpart in the SM is given by,
\[
\mu_{XX}^{i} = \frac{(\sigma_{XX}^T \mathcal{L}_7 + \sigma_{XX}^S \mathcal{L}_8) \times \text{Br}(h_i \rightarrow XX)}{(\sigma_{XX}^{SM} \mathcal{L}_7 + \sigma_{XX}^{SM} \mathcal{L}_8) \times \text{Br}^{SM}(h_i \rightarrow XX)}, \tag{2.26}
\]
where, for example, the production cross sections are given by
\[
\sigma_i^T = \sigma_{gg,7} R_{gg}^i + \sigma_{VBF,7} R_{VBF}^i + \sigma_{VH,7} R_{VH}^i, \tag{2.27}
\]
\(\sigma_{gg,7}\) is the gluon fusion cross section from Ref. [41, 42] for a SM Higgs boson with a mass of \(m_{h_i}\), and \(\mathcal{L}_{7,8}\) are the luminosities used in the experimental analysis. With this quantity, we are able to reinterpret the constraints on a heavy SM-like Higgs boson for the heavy neutral scalars in the 2HDM.

\(^2\) The rate \(h_i \rightarrow \gamma\gamma\) for \(i = 2, 3\) is always small and can be neglected here.
2.6 CP violation and Heavy Higgs Signal Rates

At this point, it is useful to gain some intuition about the impact of CP violation on the heavy Higgs to gauge boson decay channels, \( h_i \to VV \) and \( h_i \to Z h_1 \) with \( i = 2, 3 \). It is convenient to redefine the Higgs doublets and go to a basis where only one doublet, called \( \phi_1' \), gets the 246 GeV vev, while the other \( \phi_2' \) has no vev [13, 65].

We start from a special point in the parameter space where the lightest Higgs, \( h_1 \), has exactly the same couplings does the SM Higgs boson. This corresponds to having the mixing angle in Eq. (2.4) satisfy \( \alpha_b = \alpha_c = 0 \), and \( \beta - \alpha = \pi/2 \). The Higgs sector preserves CP invariance at this point. In this case, \( \phi_1' \) defined above, while \( h_{2,3} \) are excitations from \( \phi_2' \). As a result, the decay rates \( h_1 \to VV \) and \( h_1 \to Zh_1 \) both vanish for \( i = 2, 3 \). It is worth noticing that this special point can be approached without going to the real decoupling limit by sending the second doublet mass to infinity.

Next, we turn on CP violation by making \( \alpha_b = 0.5 \), but still keep \( \alpha_c = 0 \). Here we discuss an example by fixing \( \tan \beta = 20 \) (in the basis of \( \{ \phi_1, \phi_2 \} \) given in Eq. (2.3)) and vary the angle \( \alpha \), or the quantity \( \cos(\beta - \alpha) \). We also choose the heavy neutral scalar masses to be \( m_{h_2} = 400 \) GeV and \( m_{h_3} = 450 \) GeV. In Fig. 1, we plot the gluon fusion production cross section and the gauge boson branching ratios of \( h_{2,3} \) as a function of \( \cos(\beta - \alpha) \). There are several suppressed regions which can be understood from Table 1. In the case \( \alpha_c = 0 \), we have in the Type-I model,

\[
\begin{align*}
ct, 2 &= c_b, 2 = -\frac{\sin \alpha}{\sin \beta}, \quad \tc, 2 = -\tc, 2 = 0, \\
ct, 3 &= c_b, 3 = -\frac{\cos \alpha}{\sin \beta} \sin \alpha_b, \quad \tc, 3 = -\tc, 3 = -\cos \alpha_b \cot \beta .
\end{align*}
\]

First, the gluon fusion production cross section for \( h_2 \) via a top or bottom loop vanishes at \( \alpha = 0 \) (near \( \cos(\beta - \alpha) \simeq 0 \)). In the example we describe here, \( \beta = \arctan(20) \) is close to \( \pi/2 \), and \( c_{t,2} = c_{b,2} \) vanishes at \( \alpha = 0 \). Second, at \( \alpha = \pm \pi/2 \), (near \( \cos(\beta - \alpha) \simeq \pm 1 \)), the couplings \( c_{t,3} \) and \( c_{b,3} \) vanish. As a result, the production cross section for \( h_3 \) is suppressed because \( \tc, 3 \) and \( \tc, b, 3 \) are both suppressed by \( \cot \beta = 1/20 \) in this case. On the other hand, the gauge boson decays of \( h_{2,3} \) are directly controlled by \( \beta - \alpha \). We list the relevant couplings here, again for \( \alpha_c = 0 \),

\[
\begin{align*}
a_2 &= -\cos(\beta - \alpha), \quad g_{2z1} = -\frac{e}{\sin 2\theta_W} \sin(\beta - \alpha) \sin \alpha_b, \\
a_3 &= -\sin(\beta - \alpha) \sin \alpha_b, \quad g_{3z1} = \frac{e}{\sin 2\theta_W} \cos(\beta - \alpha),
\end{align*}
\]

where \( g_{iz1} \) \( (i = 2, 3) \) is the coupling between \( h_i \to Z h_1 \) defined below Eq. (2.23). These make it manifest why the heavy Higgs to gauge boson decay channels are sensitive both to a deviation from the alignment limit and to CP violation. Clearly, when \( \cos(\beta - \alpha) = \pm 1 \), the decay rates \( h_3 \to VV \) and \( h_2 \to Zh_1 \) vanish, while when \( \cos(\beta - \alpha) = 0 \), the decay rates \( h_2 \to VV \) and \( h_3 \to Zh_1 \) vanish. For the case of \( h_2 \) decay, the branching ratios are more suppressed.
Figure 1. An example showing the impact of a non-zero CP violating angle, $\alpha_b = 0.5$, and the deviation from alignment (parameterized by $\cos(\beta - \alpha)$) on the heavy Higgs production from gluon fusion at $\sqrt{s} = 8$ TeV (left panels) and their decays (right panel) in $h_i \rightarrow VV$ (red, solid) and $h_i \rightarrow Zh_1$ (blue, dashed) channels. We have fixed the other parameters to be $\tan\beta = 20$, $\alpha_c = 0$, $m_{h_2} = 400$ GeV, $m_{h_3} = 450$ GeV and $\nu = 1$.

because the decay $h_2 \rightarrow h_1 h_1$ dominates in most of the parameter space. Therefore, the most important constraints come from the $h_3 \rightarrow VV$ and $h_3 \rightarrow Zh_1$ channels.

Combining Eqs. (2.28) and (2.29), we find the $h_3 \rightarrow VV$ signal rate (production cross section $\times$ decay branching ratio) is peaked at $\cos(\beta - \alpha) = 0$, while $h_3 \rightarrow Zh_1$ vanishes at both $\cos(\beta - \alpha) = 0, \pm 1$, and is peaked in between. With these facts, one can understand the yellow and orange regions in the upper right panel of Fig. 10. One can also follow a similar analysis in order to understand the generic features in the other plots.

3 Results

In this section, we describe our method to obtain constraints from heavy Higgs searches at the LHC, and show the numerical results in a series of figures.

In the presence of CP violation, all of the three neutral scalars mix together, and we fix the lightest scalar, $h_1$, to be the 126 GeV scalar already discovered at the LHC. As discussed in the previous sections, the heavy Higgs to gauge boson decay channels, including $h_{2,3} \rightarrow WW/ZZ$ and $h_{2,3} \rightarrow Zh_1 \rightarrow l^+l^-b\bar{b}$, are not only sensitive to deviations from the
alignment limit \((\beta - \alpha = \pi/2)\), but also to the presence of CP violation \((\alpha_b, \alpha_c \neq 0)\). We use the production and decay rates calculated in Sec. 2.5 to obtain the 2HDM predictions for the heavy Higgs signal strength in these two channels. Then we compare these theory predictions to the results from the 7 and 8 TeV running of the LHC.

For the heavy Higgs search data, we use limits for masses up to a TeV from the \(h_{2,3} \rightarrow WW/ZZ\) channel \([46, 47]\) and from the \(h_{2,3} \rightarrow Zh \rightarrow l^+l^-b\bar{b}(\tau^+\tau^-)\) channel \([48, 49]\). We also take into account the \(h_{2,3} \rightarrow \tau^+\tau^-\) channel \([50]\), which gives constraints for heavy Higgs masses up to a TeV and is relevant in the Type-II model in the large \(\tan\beta\) case \([51]\).

The most up-to-date 126 GeV Higgs coupling data are given in Table 2, normalized to the appropriate luminosities. They are used to constrain the theoretical predictions for the signal rates of \(h_1\), from Sec. 2.5. We take the SM cross sections from the LHC Higgs Cross Section Working Group \([42]\). We have performed a \(\chi^2\) analysis using the results listed in Table 2.

| Channel   | \(\mu_{CMS}\)     | Ref. | \(\mu_{ATLAS}\)   | Ref. |
|-----------|--------------------|------|--------------------|------|
| \(\mu_{WW}\) | 0.83 ± 0.21        | [52] | 1.09+0.23          | [53] |
| \(\mu_{ZZ}\) | 1.0 ± 0.29         | [52] | 1.44+0.40          | [54] |
| \(\mu_{\gamma\gamma}\) | 1.13 ± 0.24       | [52] | 1.17 ± 0.27        | [55] |
| \(\mu_{bb}\)   | 0.93 ± 0.49        | [52] | 0.5 ± 0.4          | [56] |
| \(\mu_{\tau\tau}\) | 0.91 ± 0.27       | [52] | 1.4 ± 0.4          | [57] |

In Figs. 2 to 11, we show the limits derived from heavy Higgs searches and the light (126 GeV) Higgs data, together with those from the low energy electron and neutron electric dipole moments (EDM). For the EDM constraints, we use the results of Ref. \([10]\).

In these numerical results, we fix the heavy Higgs masses and the parameter \(\nu = 1\). The CP violating angle \(\alpha_c\) is fixed in the approximate \(Z_2\) symmetric model by Eq. (2.12). On the other hand, for the extended model without an approximate \(Z_2\) symmetry, \(\alpha_c\) is a free parameter. We also note that varying the parameter \(\nu\) between 0 and 1 only leads to slight changes to our results. The constraints are shown in the \(\sin\alpha_b\) versus \(\tan\beta\) plane, while varying \(\alpha\) and \(\alpha_c\). We consider both the alignment limit with \(\alpha = \beta - \pi/2\) and cases when there are small deviations from alignment, \(\cos(\beta - \alpha) = \pm \Delta\). The 126 GeV Higgs data put upper bounds on \(\Delta\) for fixed values of \(\tan\beta\). For the Type-I model, we consider \(\Delta = 0.1\), while for the Type-II model, the light Higgs coupling data constraint is stronger at large \(\tan\beta\), so we take \(\Delta = 0.02\) \([4]\). ATLAS has also limited the parameters of the 2HDM by directly searching for the heavier neutral Higgs boson, but these limits are not competitive with the Higgs coupling data for the heavy \(h_{2,3}\) masses that we consider \([45]\).
Figure 2. Heavy Higgs search constraints on the Type-I 2HDM with approximate $Z_2$ symmetry, using the $h_{2,3} \rightarrow WW/ZZ$ (yellow) and $h_{2,3} \rightarrow Zh_1 \rightarrow l^+l^-b\bar{b}$ (orange) channels. These constraints are presented in the $\sin \alpha_b$ versus $\tan \beta$ parameter space and colored regions are excluded. The left panel is for the alignment limit with $\alpha = \beta - \pi/2$, while the right panel shows the case with a deviation from that limit. Also shown in blue are the electron EDM excluded regions. In these plots, we have chosen the heavy scalar masses to be $m_{h_2} = 400$ GeV, $m_{h_3} = 450$ GeV, $m_{H^+} = 420$ GeV, and the model parameter $\nu = 1$. The other mixing angle $\alpha_c$ is a dependent quantity fixed by Eq. (2.12). In the gray region, there is no real solution for $\alpha_c$.

Figure 3. Similar to Fig. 2, but with heavy scalar masses $m_{h_2} = 550$ GeV, $m_{h_3} = 600$ GeV, $m_{H^+} = 620$ GeV. In the right panel, the red region is excluded by the 126 GeV Higgs data applied to $h_1$.

3.1 Limits from Heavy Higgs Searches in Approximate $Z_2$ Symmetric Models

We first discuss the models with an approximate $Z_2$ symmetry. Fig. 2 shows the limits on the CP violating parameter, $\alpha_b$, as a function of $\tan \beta$ in the Type-I model. In each panel, the gray area marked “theory inaccessible” has no real solution for $\alpha_c$ from Eq. (2.12). The left panel...
Figure 4. Heavy Higgs search constraints on the Type-II 2HDM with approximate $Z_2$ symmetry. The Higgs sector parameters are chosen to be the same as those in Fig. 2. The colored regions are excluded by searches for $h_{2,3} \rightarrow WW/ZZ$ (yellow), $h_{2,3} \rightarrow Zh_1 \rightarrow l^+l^-b\bar{b}$ (orange) channels, $h_{2,3} \rightarrow \tau^+\tau^-$ (magenta), 126 GeV Higgs coupling data (red), electron EDM measurements (blue), and neutron EDM limits (green). The gray region is again theoretically excluded because it contains no real solution for $\alpha_c$.

Figure 5. Similar to Fig. 4, but with heavy scalar masses $m_{h_2} = 550$ GeV, $m_{h_3} = 600$ GeV, $m_{H^\pm} = 620$ GeV.

assumes the alignment limit, $\beta - \alpha \sim \pi/2$, while the right panel allows for a small deviation from the alignment limit\footnote{The results are similar for negative $\Delta$.}. The orange area is excluded by the heavy Higgs search channel $h_{2,3} \rightarrow Zh_1 \rightarrow l^+l^-b\bar{b}$, while the yellow area is excluded by the channel $h_{2,3} \rightarrow WW/ZZ$. It is clear that the limits become quite stringent away from the alignment limit. For comparison, we include the results of Ref. [10] for the limits from the electron EDM (eEDM, the blue shaded regions are excluded). In all cases, the EDM limit and the heavy Higgs searches
exclude complementary regions. The masses of the heavy Higgs are increased to around 600 GeV in Fig. 3. In this case, the limits from heavy Higgs searches become much weaker, with the dominant excluded region coming from the eEDM searches. The mass splitting between the heavy masses is restricted by limits on the oblique parameters, which is discussed in Sec. 4.1.

Fig. 4 shows the limits on $\alpha_b$ versus $\tan \beta$ in the Type-II model. In all cases shown, there is a strong limit at large $\tan \beta \gtrsim 30 - 40$ from the heavy Higgs search, $h_{2,3} \to \tau^+ \tau^-$. Away from the alignment limit (the right panel), there is also a significant exclusion region for $\tan \beta \gtrsim 10$ from the 126 GeV Higgs parameter measurements. Around $\tan \beta \sim 1$, the electron EDM constraint vanishes due to a cancellation among the Barr-Zee diagrams as pointed out in Ref. [8]. We find the heavy Higgs searches from the gauge boson decay channels $h_{2,3} \to Zh_1$ and $h_{2,3} \to WW/ZZ$ are extremely useful and close the window of large values of $\sin \alpha_b \sim \mathcal{O}(1)$ in all cases. As the mass of the heavy particles is increased in Fig. 5, the region excluded by the heavy Higgs searches shrinks, with again the dominant exclusion coming from the eEDM and neutron EDM (nEDM, the green regions are excluded). It is worth pointing out that the neutron EDM excluded regions are shown using the central values given in [58], which however involves large uncertainties in the evaluation of hadronic matrix elements. In contrast, the heavy Higgs searches provide a robust upper limit on the CP violating angle $\alpha_b$.

3.2 Limits from Heavy Higgs Searches in the Models with no $Z_2$ Symmetry

As discussed in Sec. 2.4, if the assumption of an approximate $Z_2$ symmetry is relaxed, the theoretical relationship between $\alpha_b$ and $\alpha_c$ can be removed. In this case $\alpha_c$ becomes a free parameter. This helps to remove the theoretically inaccessible region in Figs. 2–5, and one can get a complete view of various constraints in the whole parameter space.

Figs. 6 and 7 show the constraints in the Type-I model with $\alpha_c$ chosen equal to 0 or $\alpha_b$, and with two sets of heavy Higgs masses. It is apparent that the dependence on $\alpha_c$ is rather weak. The results in the Type-II model are shown in Figs. 8 and 9. In Figs. 10 and 11, the heavy Higgs search constraints are also displayed in the $\alpha_b$ and $\cos(\beta - \alpha)$ plane.

It is also worth re-emphasizing that at low $\tan \beta \sim \mathcal{O}(1)$ the 126 GeV Higgs data puts a very weak constraint on the CP violating angle $\alpha_b$. This can also be understood from Table 1, where the lightest (126 GeV) Higgs couplings to other SM particles near the alignment limit are

$$
\begin{align*}
a_1 & \simeq \cos \alpha_b, & c_{t,1} & \simeq (1 + \Delta \cot \beta) \cos \alpha_b, & \tilde{c}_{t,1} & \simeq - \cot \beta \sin \alpha_b, \\
c_{b,1} & \simeq \begin{cases} (1 + \Delta \cot \beta) \cos \alpha_b, & \text{Type – I} \\
(1 - \Delta \tan \beta) \cos \alpha_b, & \text{Type – II} \end{cases} & \tilde{c}_{b,1} & \simeq \begin{cases} \cot \beta \sin \alpha_b, & \text{Type – I} \\
- \tan \beta \sin \alpha_b, & \text{Type – II} \end{cases}
\end{align*}
$$

(3.1)

where $\Delta = \cos(\beta - \alpha)$ and we have kept terms up to first power in $\Delta$. Clearly for small $\Delta$ and $\tan \beta \approx 1$, all CP even couplings are approximately $\cos \alpha_b$ and all CP odd couplings $\approx \pm \sin \alpha_b$. They approach the values in the SM limit when $\alpha_b \to 0$. In the presence of CP
Because the cosine function of the 126 GeV Higgs data depends on $\cos^2 \alpha_{\text{SM}}$ for sizable low $\tan \beta$, this feature has been discussed in Sec. 2.6. Furthermore, from the figures we notice that at $\alpha$ more sensitive to a non-zero CP violating angle $\alpha_b$ are suppressed in this region. The Higgs to fermion $h_{1.2} \rightarrow b\bar{b}, \tau^+\tau^-$ decay rates are not affected because the CP even and CP odd couplings contribute incoherently. $\Gamma(h_{1.2} \rightarrow f \bar{f})/\Gamma_{\text{SM}}(h_{1.2} \rightarrow f \bar{f}) = \cos^2 \alpha_b + \sin^2 \alpha_b = 1$. The Higgs to gauge boson $h_{1.2} \rightarrow WW^*, ZZ^*$ decay rates get suppressed, $\Gamma(h_{1.2} \rightarrow WW^*)/\Gamma_{\text{SM}}(h_{1.2} \rightarrow WW^*) = \cos^2 \alpha_b$. The light Higgs to diphoton decay rate in the presence of CP violation has been given in refs. [8, 10], which in this case can be simplified to $\Gamma(h_{1.2} \rightarrow \gamma\gamma)/\Gamma_{\text{SM}}(h \rightarrow \gamma\gamma) \simeq 1 - 0.81 \sin^2 \alpha_b$. As a result, the final $\chi^2$ of the fit for the 126 GeV Higgs data depends on $\cos^2 \alpha_b$, and for the SM case $\chi_{\text{SM}}^2 = \chi^2(\cos^2 \alpha_b \rightarrow 1)$. Because the $\cos^2 \alpha_b$ function is very flat near $\alpha_b = 0$, one can maintain a fit as good as in the SM for sizable $\alpha_b$.

In contrast, the heavy Higgs decay to gauge boson channels ($h_{2.3} \rightarrow VV$ and $Zh_1$) are more sensitive to a non-zero CP violating angle $\alpha_b$ and can place a stronger constraint on it. This feature has been discussed in Sec. 2.6. Furthermore, from the figures we notice that at low $\tan \beta$, the heavy Higgs search constraint is stronger than at large $\tan \beta$. This is because $h_i \rightarrow t\bar{t}$, ($i = 2, 3$) is the dominant decay mode and the branching ratio for the gauge boson decay modes of $h_i$ can be written as

$$\text{Br}_{h_i \rightarrow VV \text{ or } Zh}(\text{low } \tan \beta) \sim \frac{\Gamma_{h_i \rightarrow VV \text{ or } Zh}}{\Gamma_{h_i \rightarrow t\bar{t}}}.$$ 

Eqs. (2.28) and (2.29) tell us that these two rates around the alignment limit are both insensitive to variations of $\tan \beta$. However, as $\tan \beta$ grows to larger than $O(2)$, the other decay channels such as $h_i \rightarrow h_1h_2$ and $h_i \rightarrow b\bar{b}$ larger than $h_i \rightarrow t\bar{t}$, and they are not yet constrained by the LHC data. As a result, the gauge boson decay rates of heavy Higgs bosons are suppressed in this region.

Fig. 12 depicts 95% CL constraints in the $\tan \beta$ versus $\cos(\beta - \alpha)$ plane from heavy Higgs searches (black) and from 126 GeV Higgs data (yellow) on the Type-I (first row) and Type-II (second row) 2HDMs without approximate $Z_2$ symmetry. Different curves correspond to $\alpha_b = 0$ (dotted), 0.1 (solid) and 0.5 (dashed), and the other mixing angle $\alpha_c = 0$. For the CP conserving case ($\alpha_b = 0$), we found that the bounds are very similar to those studied in Refs. [5, 33, 34, 59]. In both Type-I and Type-II models, both heavy and light Higgs searches favor regions around the alignment limit $\cos(\beta - \alpha) = 0$. In the Type-II model when CP violation is small (bottom left panel), there is another allowed branch corresponding to $\cos(\beta + \alpha) \sim 0$ [60], but we find the heavy and light Higgs favored regions are inconsistent with each other for very large deviations from the alignment limit. In the Type-I model (first row), the light Higgs bound only depends on $\cos(\beta - \alpha)$, but is independent of $\tan \beta$ in the large $\tan \beta$ limit. The reason is that in this case the $h_1$ couplings can be approximated as $c_{\delta,1} = \sin(\beta - \alpha) \sin \alpha_b + O(1/\tan \beta)$, $\delta_{\delta,1} = -\delta_{b,1} = O(1/\tan \beta)$ and $a_1 = \sin(\beta - \alpha) \cos \alpha_b$, so their dependence on $\tan \beta$ is suppressed. On the other hand, for the Type-II model, the couplings $c_{b,1}, c_{\tau,1}$ and $\delta_{b,1}, \delta_{\tau,1}$ are enhanced at large $\tan \beta$. This explains why in the Type-II
model (second row), light Higgs data are more restrictive on the parameter space with large 
$tan \beta$. As a result, for $\alpha_b = 0.5$, the light Higgs data only favors a region with $tan \beta \lesssim 2$ 
(see the bottom right panel of Fig. 12). In contrast, we have learned that the heavy Higgs 
search data are more sensitive at small $tan \beta$ and for $\alpha_b = 0.5$ they only allow the region 
where $tan \beta \gtrsim 3$, thus there is no region in the parameter space that can be made consistent 
with both light and heavy Higgs results from LHC. Fig. 13 gives results similar to those 
in Fig. 12 but with a different set of mass parameters, $m_{h_2} = 550$ GeV, $m_{h_3} = 600$ GeV, 
$m_{H^+} = 620$ GeV. The parameter space becomes less constrained by the heavy Higgs searches 
because the production cross sections are smaller compared to those in Fig. 12.

From the above results, we can conclude that if the heavy Higgs masses lie below around 
600 GeV, the CP violating phase $\alpha_b$ is constrained to be less than around 30% throughout 
the most general parameter space. The regions which allow $\alpha_b$ close to this upper bound are 
tan $\beta \sim 1$ in the Type-II model, and tan $\beta \gtrsim 20$ in the Type-I model without an approximate 
$Z_2$ symmetry. We have also estimated the future sensitivity of the heavy Higgs search at the 
14 TeV LHC by rescaling the current limits by the square root of expected number of events 
($\sigma \times \mathcal{L}$). With 300 (3000) fb$^{-1}$ data, if the heavy Higgs masses are below 600 GeV and we 
still do not find them, the CP violating angle $\alpha_b$ will be constrained to be less than around 
10%.

Recall that the angle $\alpha_b$ parametrizes the size of CP odd mixture in the 126 GeV Higgs 
boson. The main point of this work is to show that the heavy Higgs search is relevant and 
plays a complimentary role to the other indirect searches, and sometimes it stands at the 
frontier of probing the Higgs boson CP mixture.
Figure 6. Heavy Higgs search constraints on the Type-I 2HDM without approximate $Z_2$ symmetry, i.e., in this case $\alpha_c$ is a free parameter which is allowed to vary. The color scheme for the exclusion regions is the same as in Figs. 2–5. The first two rows use the same parameters as Fig. 2, and the last two rows use the same as Fig. 3.

Figure 7. Similar to Fig. 6, but with heavy Higgs masses $m_{h_2} = 550$ GeV, $m_{h_3} = 600$ GeV, $m_{H^+} = 620$ GeV.
Figure 8. Similar to Fig. 6, but for the Type-II 2HDM without approximate $Z_2$ symmetry.

Figure 9. Similar to Fig. 7, but for the Type-II 2HDM without approximate $Z_2$ symmetry.
Figure 10. Heavy Higgs search constraints on the Type-I (first row) and Type-II (second row) 2HDM without approximate $Z_2$ symmetry, using the $h_{2,3} \to WW/ZZ$ (yellow) and $h_{2,3} \to Z h_1 \to l^+ l^- b \bar{b}$ (orange) channels. The heavy scalar masses are fixed to be $m_{h_2} = 400 \text{ GeV}$, $m_{h_3} = 450 \text{ GeV}$, $m_{H^+} = 420 \text{ GeV}$, and the model parameter $\nu = 1$. The other mixing angle $\alpha_c = 0$.

Figure 11. Similar to Fig. 10, but with heavy scalar masses $m_{h_2} = 550 \text{ GeV}$, $m_{h_3} = 600 \text{ GeV}$, $m_{H^+} = 620 \text{ GeV}$.
**Figure 12.** Heavy Higgs search (black) and 126 GeV Higgs data (yellow) constraints at 95% CL on the Type-I (first row) and Type-II (second row) 2HDM without approximate $Z_2$ symmetry. Different curves correspond to $\alpha_b = 0$ (dotted), 0.1 (solid) and 0.5 (dashed). The heavy Higgs curves include the combination of constraints from $h_{2,3} \rightarrow WW/ZZ$, $h_{2,3} \rightarrow Zh_1 \rightarrow l^+ l^- b\bar{b}$ and $h_{2,3} \rightarrow \tau^+ \tau^-$ channels. The heavy scalar masses are fixed to be $m_{h_2} = 400$ GeV, $m_{h_3} = 450$ GeV, $m_{H^\pm} = 420$ GeV, and the model parameter $\nu = 1$. The other mixing angle $\alpha_c = 0$.

**Figure 13.** Similar to Fig. 12, but for heavy Higgs masses $m_{h_2} = 550$ GeV, $m_{h_3} = 600$ GeV, $m_{H^\pm} = 620$ GeV.
4 Limits from $B$ Decays, Oblique Parameters, and $(g - 2)_\mu$

The CP violating 2HDM is also limited by measurements in $B$ decays, the oblique parameters, and $(g - 2)_\mu$. In Type-II models the charged Higgs mass is restricted by $B$ data to be greater than $m_{H^+} \sim 340$ GeV for all values of $\tan \beta$. In both Type-1 and Type-2 models, measurements in the $B$ system prefer $\tan \beta > 1$ \cite{5, 61, 62}.

4.1 Limits from Electroweak Oblique Parameters

The allowed parameters are restricted by measurements of the oblique parameters. The general results for $S,T$ and $U$ in a 2HDM are given in Refs. \cite{3, 63–65}. In the alignment limit, $\cos \alpha = \sin \beta$ and $\sin \alpha = -\cos \beta$, the results simplify considerably,

$$\alpha \Delta T = \frac{1}{16\pi^2 v^2} \left\{ \sin^2 \alpha_b F(m_{H^+}^2, m_{h_1}^2) + (1 - \sin^2 \alpha_b \sin^2 \alpha_c) F(m_{H^+}^2, m_{h_2}^2) \right.$$  

$$+(1 - \sin^2 \alpha_b \cos^2 \alpha_c) F(m_{H^+}^2, m_{h_3}^2) - \cos^2 \alpha_c \sin^2 \alpha_b F(m_{h_1}^2, m_{h_2}^2)$$  

$$- \sin^2 \alpha_c \sin^2 \alpha_b F(m_{h_1}^2, m_{h_3}^2) - \cos^2 \alpha_b F(m_{h_2}^2, m_{h_3}^2)$$  

$$+ 3 \cos^2 \alpha_b \left[ F(M_Z^2, m_{h_1}^2) - F(M_W^2, m_{h_1}^2) \right]$$  

$$+ 3 \sin^2 \alpha_c \sin^2 \alpha_b \left[ F(M_Z^2, m_{h_2}^2) - F(M_W^2, m_{h_2}^2) \right]$$  

$$+ 3 \cos^2 \alpha_c \sin^2 \alpha_b \left[ F(M_Z^2, m_{h_3}^2) - F(M_W^2, m_{h_3}^2) \right]$$  

$$- 3 \left[ F(M_Z^2, M_{H,ref}^2) - F(M_W^2, M_{H,ref}^2) \right] \right\} , \quad (4.1)$$

where the last line is the subtraction of the SM Higgs contribution evaluated at the reference scale, $M_{H,ref}$, at which the fit to the data is performed. The function $F(x, y)$ is,

$$F(x, y) = \frac{x + y}{2} \left( \frac{xy}{(x - y)} \log \frac{x}{y} \right) .$$

$$F(x, x) = 0 ,$$

$$F(x, y) \xrightarrow{y \gg x} \frac{y}{2} . \quad (4.2)$$

With $\alpha_c = 0$, we obtain the simple form,

$$\alpha \Delta T = \frac{1}{12\pi^2 v^2} \left\{ \Delta_2 \Delta_3 \cos^2 \alpha_b + \left[ \Delta_1 \Delta_2 - 2(\Delta_3 - \Delta_1)(M_W - M_Z) \right] \sin^2 \alpha_b \right\} \quad (4.3)$$

and $\Delta_i \equiv m_{H^+} - m_{h_i}$. Eq. (4.3) is in agreement with Ref. \cite{66} in the limit $\alpha_b = 0$. 

---

- 21 -
The result for $\Delta S$ also takes a simple form in the alignment limit [63],

$$
\Delta S = \frac{1}{24\pi} \left\{ \cos^2 2\theta_W G(m_{H^+}^2, m_{H^+}^2, M_Z^2) + \sin^2 \alpha_b \left[ \cos^2 \alpha_c G(m_{h_1}^2, m_{h_2}^2, M_Z^2) 
+ \sin^2 \alpha_c G(m_{h_1}^2, m_{h_3}^2, M_Z^2) + \sin^2 \alpha_c \hat{G}(m_{h_2}^2, M_Z^2) + \cos^2 \alpha_c \hat{G}(m_{h_3}^2, M_Z^2) \right] 
+ \cos^2 \alpha_b \left[ \hat{G}(m_{h_1}^2, M_Z^2) + G(m_{h_2}^2, m_{h_3}^2, M_Z^2) \right] 
+ \ln \left( \frac{m_{h_1}^2 m_{h_2}^2 m_{h_3}^2}{m_{H^+}^6} \right) 
- \left[ \hat{G}(M_{H^+, \text{ref}}^2, M_Z^2) + \ln \left( \frac{M_{H^+, \text{ref}}^2}{m_{H^+}^2} \right) \right] \right\} .
$$

(4.4)

Analytic results for $G(x, y, z)$ and $\hat{G}(x, y)$ are given in the appendix of Ref. [63].
We use the Gfitter fit to the electroweak data $[67]$,

\begin{align*}
S &= 0.05 \pm 0.11 \\
T &= 0.09 \pm 0.13 \\
U &= 0.01 \pm 0.11 ,
\end{align*}

(4.5)

with a reference value for the SM Higgs mass, $M_{H,\text{ref}} = 125$ GeV. The $STU$ correlation matrix is,

\begin{equation}
\rho_{ij} = \begin{pmatrix}
1 & 0.90 & -0.59 \\
0.90 & 1 & -0.83 \\
-0.59 & -0.83 & 1
\end{pmatrix},
\end{equation}

(4.6)

and the $\chi^2$ is defined as

\begin{equation}
\Delta \chi^2 = \Sigma_{ij}(\Delta X_i - \Delta \hat{X}_i)(\sigma^2)^{-1}_{ij}(\Delta X_j - \Delta \hat{X}_j) ,
\end{equation}

(4.7)

where $\hat{X}_i = \Delta S, \Delta T$, and $\Delta U$ are the central values of the fit in Eq. (4.5), $\hat{X}_i = \Delta S, \Delta T$, and $\Delta U$ are the parameters in the 2HDM (Eqs. (4.1) and (4.4)), $\sigma_i$ are the errors given in Eq. (4.5) and $\sigma^2_{ij} = \sigma_i \rho_{ij} \sigma_j$.

In Fig. 14 we show the 95\% confidence level allowed regions for $\alpha_b = \alpha_c$ and $\alpha_c = 0$. For $\alpha_b$ close to 1, there is some interesting structure due to the interplay of the $\Delta S$ and $\Delta T$ limits. For $| \sin \alpha_b | < 0.5$, the results are well approximated by the limit from $\Delta T$ only,

\begin{equation}
-80 \text{ GeV} < \Delta_2 < 120 \text{ GeV} .
\end{equation}

(4.8)

4.2 Limits from muon $g-2$

The experimentally measured value of $(g-2)_\mu = a_\mu$ places a weak constraint on the parameters of the CP violating 2HDM. The deviation between the experimental number and the SM theory prediction is $[68]$,

\begin{equation}
\Delta a_\mu = a_{\mu}^{\text{exp}} - a_{\mu}^{\text{SM}} = 265(85) \times 10^{-11} .
\end{equation}

(4.9)

The one-loop contributions from the Higgs sector in the 2HDM to $\Delta a_\mu$ are numerically small. The larger Higgs sector contributions come from the 2-loop Barr-Zee type diagrams with a closed fermion/gauge-boson/heavy-Higgs loop. This class of diagrams can be enhanced by factors of $M^2/m^2_\mu$ relative to the 1-loop diagrams, where $M$ is a heavy Higgs or heavy fermion mass. For completeness, these results are given in Appendix C.

In Figs. 15 and 16, we show the contributions to $\Delta a_\mu$ in the 2HDM for relatively heavy $m_{2,3}$ and $m_{H^+}$ in units of $10^{-11}$. For $| \sin \alpha_b | \lesssim 0.5$, there is almost no sensitivity to the CP violating phase. The largest contribution is found in the Type-II model for large $\tan \beta$ and is of opposite sign to that needed to explain the discrepancy of Eq. (4.9).
Figure 15. Contributions to $(g - 2)_{\mu}$ in the CP violating Type-I 2HDM from the Barr-Zee diagrams. The heavy scalar masses are fixed to be $m_{h_2} = 400$ GeV, $m_{h_3} = 450$ GeV, $m_{H^+} = 420$ GeV, and the model parameter $\nu = 1$.

Figure 16. Similar to Fig. 15 but for Type-II 2HDM.
5 Conclusion

The CP mixture of the 126 GeV Higgs boson is an important property of the Higgs sector that deserves further scrutiny. A non-zero CP component is theoretically well motivated and may be the origin of the cosmic baryon asymmetry. An important consequence of the 126 GeV Higgs boson having a sizable CP odd mixture is that the new physics responsible for this cannot be decoupled and must lie near the electroweak scale.

In the context of CP violating, flavor conserving two-Higgs-doublet models, we studied the impact of the heavy Higgs searches at the LHC on the CP violating parameters. In this class of models, CP violation appears in the neutral Higgs sector, where there are two more real scalars ($h_{2,3}$) in addition to the lightest 126 GeV one. The couplings of the heavy Higgs scalars with electroweak gauge bosons are very sensitive to the CP violation in the Higgs sector. Turning on a CP odd mixture in the 126 GeV Higgs boson will also turn on the heavy Higgs decay channels into gauge bosons, $h_{2,3} \rightarrow WW/ZZ$ and $Zh_1$. There is data from the LHC from the search for a SM like Higgs boson in these decay channels, and the non-discovery of a heavy Higgs can be re-interpreted as constraints on the allowed deviation from the alignment limit in the two-Higgs-doublet models without CP violation.

In this work, we point out that heavy Higgs searches are also extremely useful for constraining Higgs sector CP violation and in particular the CP mixture of the 126 GeV Higgs boson. We demonstrate that the constraints from heavy Higgs searches are largely complimentary to the low energy EDM constraints. We compare our results with the limits from the global fit to the 126 GeV Higgs data, and find they can place much stronger limits than the light Higgs coupling fit, especially in the interesting regions when there are destructive contributions to the EDM. We find in these regions that the heavy Higgs searches are at the frontier of probing Higgs sector CP violation. The current limit on the CP violating mixing angle, parametrized by $\alpha_b$, is constrained to be less than 30%, and the LHC heavy Higgs search can further narrow down the angle to less than a 10% level with the high luminosity runs. We also expect our work to be a roadmap for the future searches for Higgs sector CP violation and the exciting interplay across various experimental frontiers.

For completeness, we have also explored other relevant constraints from electroweak oblique parameters, the muon $g - 2$ and from B physics, and discussed their implications on the heavy Higgs parameter limits in CP violating 2HDMs.
A Solving the potential parameters in the approximate $Z_2$ case

In this section, we list the relations between the potential parameters and the phenomenological parameters listed in Eq. (2.3) in the approximate $Z_2$ symmetric 2HDMs.

\begin{align*}
m_{11}^2 &= \lambda_1 v^2 \cos^2 \beta + (\lambda_3 + \lambda_4) v^2 \sin^2 \beta - \text{Re}(m_{12}^2 e^{i\xi}) \tan \beta + \text{Re}(\lambda_5 e^{2i\xi}) v^2 \sin^2 \beta, \quad (A.1) \\
m_{22}^2 &= \lambda_2 v^2 \sin^2 \beta + (\lambda_3 + \lambda_4) v^2 \cos^2 \beta - \text{Re}(m_{12}^2 e^{i\xi}) \cot \beta + \text{Re}(\lambda_5 e^{2i\xi}) v^2 \cos^2 \beta, \quad (A.2) \\
\text{Im}(m_{12}^2) &= v^2 \sin \beta \cos \beta \text{Im}(\lambda_5), \quad (A.3) \\
\lambda_1 &= \frac{m_{h_1}^2 \sin^2 \alpha \cos^2 \alpha_b + m_{h_2}^2 R_{21}^2 + m_{h_3}^2 R_{31}^2}{v^2 \cos \beta^2} - \nu \tan^2 \beta, \quad (A.4) \\
\lambda_2 &= \frac{m_{h_1}^2 \cos^2 \alpha \cos^2 \alpha_b + m_{h_2}^2 R_{22}^2 + m_{h_3}^2 R_{32}^2}{v^2 \sin \beta^2} - \nu \cot^2 \beta, \quad (A.5) \\
\lambda_3 &= 2\nu - \text{Re}\lambda_5 - \frac{2m_{H_0}^2}{v^2}, \quad (A.6) \\
\lambda_4 &= \nu - \frac{m_{h_1}^2 \sin \alpha \cos \alpha \cos^2 \alpha_b - m_{h_2}^2 R_{21} R_{22} - m_{h_3}^2 R_{31} R_{32}}{v^2 \sin \beta \cos \beta} - \lambda_4 - \text{Re}\lambda_5, \quad (A.7) \\
\text{Re}\lambda_5 &= \nu - \frac{m_{h_1}^2 \sin^2 \alpha_b + \cos^2 \alpha_b \left( m_{h_2}^2 \sin^2 \alpha_c + m_{h_3}^2 \cos^2 \alpha_c \right)}{v^2} \quad (A.8) \\
\text{Im}\lambda_5 &= \frac{2 \cos \alpha_b}{v^2 \sin \beta} \left[ (m_{h_2}^2 - m_{h_3}^2) \cos \alpha \sin \alpha_c \cos \alpha_c + (m_{h_1}^2 - m_{h_2}^2 \sin^2 \alpha_c - m_{h_3}^2 \cos^2 \alpha_c) \sin \alpha \sin \alpha_b \right]. \quad (A.9) \\
\text{There is an additional constraint,} \\
\tan \beta &= \frac{(m_{h_2}^2 - m_{h_3}^2) \cos \alpha_c \sin \alpha_c + (m_{h_1}^2 - m_{h_2}^2 \sin^2 \alpha_c - m_{h_3}^2 \cos^2 \alpha_c) \tan \alpha \sin \alpha_b}{(m_{h_2}^2 - m_{h_3}^2) \tan \alpha \cos \alpha_c \sin \alpha_c - (m_{h_1}^2 - m_{h_2}^2 \sin^2 \alpha_c - m_{h_3}^2 \cos^2 \alpha_c) \sin \alpha_b}. \quad (A.10)

B Tri-linear Higgs Couplings

From the quartic terms in the scalar potential Eq. (2.1), we can obtain the interactions between three neutral scalars, in the basis of $(H_1^0, H_2^0, A^0)$,

\begin{align*}
\mathcal{L}_{ss} &= \frac{1}{4}(A^0)^3 \cos \beta \left\{ 2 \sin \beta \text{Im}\lambda_5 - \cos \beta \text{Im}\lambda_5 \right\} \\
&+ \frac{1}{8}(A^0)^2 \left\{ -5 H_1^0 \cos \beta + H_2^0 \cos(3\beta) - H_2^0 (5 \sin \beta + \sin(3\beta)) \right\} \text{Re}\lambda_5 \\
&+ 4 \left[ \sin^2 \beta \lambda_1 + H_2^0 \cos \beta \sin \beta \lambda_1 + H_2^0 \cos \beta \sin \beta \lambda_2 + (H_1^0 \cos^3 \beta + H_2^0 \sin^3 \beta) (\lambda_3 + \lambda_4) \right] \right\} \\
&+ \frac{1}{4} A^0 \left\{ 4H_1^0 H_2^0 + ((H_1^0)^2 + (H_2^0)^2) \sin(2\beta) \right\} \text{Im}\lambda_5 + H_2^0 \left( 2H_1^0 - H_2^0 \cos(2\beta) + H_1^0 \sin(2\beta) \right) \text{Im}\lambda_5 \\
&+ \frac{1}{2} \left\{ H_2^0 \sin \beta \left[ (H_2^0)^2 \lambda_2 + (H_1^0)^2 (\lambda_3 + \lambda_4 + \text{Re}\lambda_5) \right] + H_1^0 \cos \beta \left[ (H_1^0)^2 \lambda_1 + (H_2^0)^2 (\lambda_3 + \lambda_4 + \text{Re}\lambda_5) \right] \right\}. \quad (B.1)
\end{align*}
From these terms one can readily obtain the $h_i h_j h_k$ interactions in the mass eigenstate basis $(h_1, h_2, h_3)$ using the orthogonal matrix $R$ from Eq. (2.4). In particular, the $g_{i11}(i = 2, 3)$ coefficients used in Eq. (2.24) are

$$g_{i11} = \frac{1}{2} \sum_{a \leq b \leq c} \frac{\partial^3 \mathcal{L}_{3s}}{\partial H_a \partial H_b \partial H_c} \frac{\partial H_a}{\partial h_1} \frac{\partial H_b}{\partial h_i} = \frac{1}{2} \sum_{a \leq b \leq c} \frac{\partial^3 \mathcal{L}_{3s}}{\partial H_a \partial H_b \partial H_c} R_{1a} R_{1b} R_{1c}, \quad (B.2)$$

where $\{H_a\} = (H^0_1, H^0_2, A^0)$.

C  Formula for $g - 2$

The magnetic and electric dipole moments of a fermion $f$ correspond to the real and imaginary parts of the Wilson coefficient $c$ of the effective operator

$$\mathcal{L}_{eff} = c \bar{f} L \sigma_{\mu \nu} f R F^{\mu \nu} + \text{h.c.}, \quad (C.1)$$

where in the Type-I and Type-II 2HDMs we consider the main contributions to the coefficient $c$ that arise from the two-loop Barr-Zee type diagrams. It is straightforward to translate the electron EDM results to the corresponding muon anomalous dipole moment. The prescription for the translation is,

$$a_\mu = \frac{2 m^2_\mu}{e Q_\mu m_e} \times \begin{cases} 
\frac{d^0_e}{d^0_e} \left( c_e \rightarrow \bar{c}_\mu \right), & h\gamma\gamma, hZ\gamma \text{ diagrams} \\
\frac{d^2_e}{d^2_e} \left( \text{Im} \left( a_{W^+ H^- h_i} \right) \rightarrow -\text{Re} \left( a_{W^+ H^- h_i} \right) \right), & W^\pm H_\mp \gamma \text{ diagrams} \ (S) \\
\frac{d^2_e}{d^2_e} \left( \text{Im} \left( c^*_{tRbLH^+} c_{\bar{v}_e R H^+} \right) \right), & W^\pm H_\mp \gamma \text{ diagrams} \ (F) \\
\rightarrow -\text{Re} \left( c^*_{tRbLH^+} c_{\bar{v}_e R H^+} \right), & W^\pm H_\mp \gamma \text{ diagrams} \ (F) 
\end{cases}$$

where $AB\gamma$ corresponds to those Barr-Zee diagrams with $h_1$ lines connected to the upper loop, and the S/F in the bracket corresponds to heavy Higgs scalars/SM fermions running in the upper loop. The $h\gamma\gamma, hZ\gamma$ and $W^\pm H_\mp \gamma$ diagram (S) contributions to the EDM have been summarized in Refs. [10, 69]. The $W^\pm H_\mp \gamma$ diagram (F) contributions to the EDM vanish in 2HDMs with approximate $Z_2$ symmetry, but have been calculated in a more general framework in Ref. [70]. We perform the above translation based on results in Ref. [70]. See also Ref. [71] for a recent work on $g - 2$ in a 2HDM.
We list below the analytic results for the contributions to the muon $g-2$ in a 2HDM:

\[
(\Delta a_\mu)^{\gamma\gamma} = \frac{G_F m_\mu^2 N_C Q_\mu^2}{2\sqrt{2}\pi} \sum_{i=1}^{3} \left[ -c_{f,i}c_{\mu,i} f(z_i^f) + \tilde{c}_{f,i}\tilde{c}_{\mu,i} g(z_i^f) \right],
\]

\[
(\Delta a_\mu)^{Z\gamma} = \frac{G_F m_\mu^2 N_C g_{Z\mu}^2 g_{Zf}^2}{8\sqrt{2}\pi^2} \sum_{i=1}^{3} \left[ -c_{f,i}c_{\mu,i} f(z_i^Z) + \tilde{c}_{f,i}\tilde{c}_{\mu,i} g(z_i^Z) \right],
\]

\[
(\Delta a_\mu)^{h\gamma} = \frac{G_F m_\mu^2}{8\sqrt{2}\pi^2} \sum_{i=1}^{3} \left[ (6 + \frac{1}{z_w}) f(z_w^i) + (10 - \frac{1}{z_w}) g(z_w^i) \right] (-c_{\mu,i}) a_i,
\]

\[
(\Delta a_\mu)^{h_Z\gamma} = \frac{G_F m_\mu^2}{32\sqrt{2}\pi^4} \sum_{i=1}^{3} \left[ (6 - \sec^2 \theta_W + \frac{2 - \sec^2 \theta_W}{2z_w}) f(z_w^i, \cos^2 \theta_W) \right.
\]
\[+ \left. \left( 10 - 3\sec^2 \theta_W - \frac{2 - \sec^2 \theta_W}{2z_w} \right) g(z_w^i, \cos^2 \theta_W) \right] (-c_{\mu,i}) a_i,
\]

\[
(\Delta a_\mu)^{h_H^+} = \frac{G_F m_\mu^2}{8\sqrt{2}\pi^3} \left( \frac{v}{m_{H^+}} \right)^2 \sum_{i=1}^{3} \left[ f(z_H^i) - g(z_H^i) \right] (-c_{\mu,i}) \tilde{\lambda}_i
\]

\[
(\Delta a_\mu)^{h_Z}\gamma = \frac{G_F m_\mu^2}{32\sqrt{2}\pi^4} \left( \frac{v}{m_{H^+}} \right)^2 \sum_{i=1}^{3} \left[ f(z_H^i, m_{H^+}^2/M_H^2) - g(z_H^i, m_{H^+}^2/M_H^2) \right] (-c_{\mu,i}) \tilde{\lambda}_i,
\]

\[
(\Delta a_\mu)^{h_{W_H}} = -\frac{G_F m_\mu^2 c_{H^+\mu e}}{64\sqrt{2}\pi^2} \sum_{i=1}^{3} \left[ \frac{\sin^2 \theta_W}{2} \sum \left( I_4(m_{H^+}^2/m_{H^+}^2 a_i) - I_3(m_{H^+}^2/m_{H^+}^2 a_i) \right) (-Re(a_{W^+H^+})) \right]
\]

\[
(\Delta a_{\mu,1h})^\gamma = \left( \frac{3g^2}{16\pi^2} \right) \left( \frac{g^2 m_\mu^2}{2\sin^2 \theta_W} \right) \left( \frac{2}{3} F_{H^+} - \frac{1}{3} F_{H^+} \right),
\]

where $z_f^f = m_f^2/m_{H_f}^2$ ($f = t, b$), $z_w^i = M_W^2/m_{H_f}^2$, $z_H^i = m_{H^+}^2/m_{H_f}^2$, and $c_{e,i} = c_{\mu,i} = c_{\tau,i}$, $\tilde{c}_{e,i} = c_{\mu,i} = \tilde{c}_{\tau,i}$ can be obtained from Table 1.

The relevant coefficients are,

\[
g_{Zf}^f = \frac{g^2}{2\cos \theta_W} \left( T_3^f - 2Q_f \sin^2 \theta_W \right),
\]

\[
g_{WWZ} = e \cot \theta_W,
\]

\[
g_{ZH^+H^-} = \frac{1}{2} e \cot \theta_W (1 - \tan^2 \theta_W),
\]

\[
\tilde{\lambda}_i = R_{i1} \cdot (\lambda_3 \cos^2 \beta + (\lambda_1 - \lambda_4 - \text{Re} \lambda_5) \sin^2 \beta)
\]

\[+ R_{i2} \cdot (\lambda_3 \sin^2 \beta + (\lambda_2 - \lambda_4 - \text{Re} \lambda_5) \cos^2 \beta) \sin \beta
\]

\[+ R_{i3} \cdot \text{Im} \lambda_5 \sin \beta \cos \beta,
\]

\[
a_{W^+H^-} = -\sin \beta R_{i1} + \cos \beta R_{i2} + i R_{i3},
\]

\[
c_{iH^+H^+} = \cot \beta,
\]

\[
c_{H^+\mu e} = \begin{cases} 
\cot \beta & \text{Type I} \\
- \tan \beta & \text{Type II} 
\end{cases}
\]  

\[\text{(C.4)}\]
The relevant loop functions are,

\[ h_0(z) = \frac{z^4}{2} \int_0^1 dx \int_0^1 dy \frac{x^3 y^3 (1-x)}{(z^2 x(1-xy) + (1-y)(1-x))^2}, \]

\[ f(z) = \frac{z}{2} \int_0^1 dx \frac{1 - 2x(1-x)}{x(1-x) - z} \log \frac{x(1-x)}{z}, \]

\[ g(z) = \frac{z}{2} \int_0^1 dx \frac{1}{x(1-x) - z} \log \frac{x(1-x)}{z}, \]

\[ h(z) = \frac{z}{2} \int_0^1 dx \frac{1}{x(1-x) - z} \left(1 + \frac{z}{x(1-x) - z} \log \frac{x(1-x)}{z}\right), \]

\[ \tilde{f}(x, y) = \frac{y f(x)}{y-x} + \frac{x f(y)}{x-y}, \]

\[ \tilde{g}(x, y) = \frac{y g(x)}{y-x} + \frac{x g(y)}{x-y}, \]

\[ I_{4,5}(m_1^2, m_2^2) = \frac{M_W^2}{m_{H^+}^2 - M_W^2} \left( I_{4,5}(M_W^2, m_1^2) - I_{4,5}(m_2^2, m_1^2) \right), \]

\[ I_4(m_1^2, m_2^2) = \int_0^1 dz (1-z)^2 \left(z - 4 + z \frac{m_{H^+}^2 - m_2^2}{M_W^2}\right) \]
\[ \times \frac{m_1^2}{M_W^2 (1-z) + m_2^2 z - m_1^2 z (1-z)} \log \frac{M_W^2 (1-z) + m_2^2 z}{m_1^2 z (1-z)}, \]

\[ I_5(m_1^2, m_2^2) = \int_0^1 dz \frac{m_1^2 z (1-z)^2}{M_W^2 (1-z) + m_2^2 z - m_1^2 z (1-z)} \log \frac{M_W^2 (1-z) + m_2^2 z}{m_1^2 z (1-z)}, \]

\[ Sp(z) = -\int_0^z t^{-1} \ln(1-t) dt, \]

\[ T(z) = \frac{1 - 3z \pi^2}{z^2} - \frac{1}{z} - \left(1 - \frac{1}{z}\right) \left(2 - \frac{1}{z}\right) \left(1 - \frac{1}{z}\right) Sp(1-z), \]

\[ B(z) = \frac{1}{z} + \frac{2z - 1 - 3 \pi^2}{z^2} + \left(1 - \frac{1}{z}\right) \ln z - \left(2 - \frac{1}{z}\right) \left(1 - \frac{1}{z}\right) Sp(1-z), \]

\[ F_t = \frac{T(m_{H^+}^2/m_1^2) - T(M_W^2/m_1^2)}{m_{H^+}^2/m_1^2 - M_W^2/m_1^2}, \]

\[ F_b = \frac{B(m_{H^+}^2/m_1^2) - B(M_W^2/m_1^2)}{m_{H^+}^2/m_1^2 - M_W^2/m_1^2}. \]  \( \text{(C.5)} \)
