The Asymptotic Behavior of Grassmannian Codes

Simon R. Blackburn and Tuvi Etzion, Fellow, IEEE

Abstract—The iterated Johnson bound is the best known upper bound on a size of an error-correcting code in the Grassmannian \( G_q(n, k) \). The iterated Schönheim bound is the best known lower bound on the size of a covering code in \( G_q(n, k) \). We use probabilistic methods to prove that both bounds are asymptotically attained for fixed \( k \) and fixed radius, as \( n \) approaches infinity. We also determine the asymptotics of the size of the best Grassmannian codes and covering codes when \( n-k \) and the radius are fixed, as \( n \) approaches infinity.

Index Terms—Covering bound, Grassmannian, hypergraph, packing bound, constant dimension code.

I. INTRODUCTION

Let \( \mathbb{F}_q \) be the finite field of order \( q \) and let \( n \) and \( k \) be integers such that \( 0 \leq k \leq n \). The Grassmannian \( G_q(n, k) \) is the set of all \( k \)-dimensional subspaces of \( \mathbb{F}_q^n \). We have that

\[
|G_q(n, k)| = \binom{n}{k}_q = \frac{q^n}{k!} \prod_{i=0}^{k-1} \left( q^n - q^i \right),
\]

where \( \binom{n}{k}_q \) is the \( q \)-ary Gaussian binomial coefficient. A natural measure of distance in \( G_q(n, k) \) is the subspace metric \([1,10]\) given by

\[
d_S(U, V) \triangleq 2k - 2 \dim(U \cap V)
\]

for \( U, V \in G_q(n, k) \). We say that \( C \subseteq G_q(n, k) \) is an \((n, M, d, k)_q\) code in the Grassmann space if \( |C| = M \) and \( d_S(U, V) \geq d \) for all distinct \( U, V \in C \). Such a code \( C \) is also called a constant dimension code. The subspaces in \( \mathbb{C} \) are called codewords. (Note that the distance between any pair of elements of \( G_q(n, k) \) is even. Because of this, some authors define the distance between subspaces \( U \) and \( V \) as \( d_S(U, V) \).) An important observation is the following: a code \( C \) in the Grassmann space \( G_q(n, k) \) has minimum distance \( 2\delta+2 \) or more if and only if each subspace in \( G(n, k-\delta) \) is contained in at most one codeword. There is a ‘dual’ notion to a Grassmannian code, known as a \( q \)-covering design: we say that \( C \subseteq G_q(n, k) \) is a \( q \)-covering design \( \mathcal{C}_q(n, k, r) \) if each element of \( G_q(n, r) \) is contained in at least one element of \( C \). If each element of \( G_q(n, r) \) is contained in exactly one element of \( C \), we have a Steiner structure, which is both an optimal Grassmannian code and an optimal \( q \)-covering design \([12,21]\).

Codes and designs in the Grassmannian have been studied extensively in the last five years due to the work by Koetter and Kschischang \([16]\) in random network coding, who showed that an \((n, M, d, k)_q\) code can correct any \( t \) packet insertions and any \( s \) packet erasures, as long as \( 2t + 2s < d \). Our goal in this paper is to examine cases in which we can determine the asymptotic behavior of codes and designs in the Grassmannian.

Let \( A_q(n, d, \delta) \) denote the maximum number of codewords in an \((n, M, d, k)_q\) code. The packing bound is the best known asymptotic upper bound for \( A_q(n, d, k) \). If we write \( d = 2\delta + 2 \), we have

\[
A_q(n, 2\delta+2, k) \leq \frac{n}{k} \binom{n}{k}_q.
\]

This bound is proved by noting that in an \((n, M, 2\delta+2, k)_q\) code, each \((k-\delta)\)-dimensional subspace can be contained in at most one codeword. Bounds on \( A_q(n, d, k) \) were given in many papers, e.g., \([9,10,11,12,16,17,23,25,26]\). In particular, the well-known Johnson bound for constant weight codes was adapted for constant dimension codes independently in \([11,12,20]\) to show that

\[
A_q(n, \delta+k+2, k) \leq \frac{n}{k} \binom{n}{k}_q A_q(n-1, \delta+2, k-1).
\]

By iterating this bound, using the observation that \( A_q(n, \delta+k+2, k) = 1 \) for all \( k \leq \delta \), we obtain the iterated Johnson bound:

\[
A_q(n, 2\delta+2, k) \triangleq \left[ \frac{n}{k} \binom{n}{k}_q A_q(n-1, \delta+2, k-1) \right]^{\lfloor k-\delta \rfloor}.
\]

It is not difficult to see that the iterated Johnson bound is always stronger than the packing bound (indeed, the packing bound may be derived as a simple corollary of the iterated Johnson bound). However, the main goal of this paper is to prove that the packing bound (and so the iterated Johnson bound) is attained asymptotically for fixed \( k \) and \( \delta \), \( k, \delta \geq 0 \), when \( n \) tends to infinity. In other words, we will prove the following theorem, in which the term \( A(n) \sim B(n) \) means that \( \lim_{n \to \infty} A(n)/B(n) = 1 \).

Theorem 1: Let \( k \) and \( \delta \) be fixed integers, with \( 0 \leq \delta \leq k \) and such that \( q \) is a prime power. Then

\[
A_q(n, 2\delta+2, k) \sim \frac{n}{k} \binom{n}{k}_q \] \hspace{1cm} (2)

as \( n \to \infty \).

In fact, the proof of our theorem shows a little more than this: see the proof of the theorem and the comment in the last section of this paper. Our proof of the lower bound...
is probabilistic, making use of some of the theory of quasi-random hypergraphs. There are known explicit constructions that produce codes whose size is within a constant factor of the packing bound as \( n \to \infty \). Currently, the best codes known are the codes of Etzion and Silberstein \[^9\] that are obtained by extending the codes of Silva, Kschischang, and Koetter \[^{22}\] using a ‘multi-level construction’. If \( q = 2 \) and \( \delta = 2 \), then the ratio between the size of the code and the packing bound is 0.6657, 0.6274, and 0.625 when \( k = 4 \), \( k = 8 \), and \( k = 30 \) respectively, as \( n \) tends to infinity. When \( k = 3 \), the ratio of 0.7101 in \[^{22}\] was improved in \[^{10}\] to 0.7657. The Reed–Solomon-like codes of \[^{16}\] represented as a lifting of codewords of maximum rank distance codes \[^{22}\] approach the packing bound as \( n \to \infty \) when one of \( \delta \) or \( q \) also tends to infinity \[^{10}\] Lemma 19. Theorem 1 shows that there exist codes approaching the packing bound as \( n \to \infty \) even when \( \delta \) and \( q \) are fixed; of course, the challenge is now to construct such codes explicitly.

The paper also proves a similar result for \( q \)-covering designs. Let \( C_q(n, k, r) \) denote the minimum number of \( k \)-dimensional subspaces in a \( q \)-covering design \( C_q(n, k, r) \). Bounds on \( C_q(n, k, r) \) can be found in \[^{8}\]. \[^{13}\]. Setting \( r = k - \delta \), the covering bound states that

\[
C_q(n, k, r) \geq \frac{\left\lceil \frac{n}{k - \delta} \right\rceil}{q^{k - \delta}}.
\]

(3)

This bound may be proved by observing that in a \( C_q(n, k, k - \delta) \) covering design each \( (k - \delta) \)-dimensional subspace must be contained in at least one codeword. The Schönheim bound is an analogous result to the Johnson bound above:

\[
C_q(n, k, r) \geq \frac{q^n - 1}{q^k - 1} C_q(n - 1, k - 1, r - 1).
\]

This bound implies the iterated Schönheim bound \[^{13}\]:

\[
C_q(n, k, r) \geq \left[ \frac{q^n - 1}{q^k - 1} \left[ \frac{q^{n-1} - 1}{q^{k-1} - 1} \cdots \left[ \frac{q^{n-r+1} - 1}{q^{k-r+1} - 1} \cdots \right] \right] \right].
\]

(4)

The iterated Schönheim bound is always at least as strong as the covering bound. But the following theorem shows that when \( k \) and \( \delta \) are fixed with \( n \to \infty \) the covering bound (and so the iterated Schönheim bound) is attained asymptotically:

**Theorem 2:** Let \( q \), \( k \) and \( \delta \) be fixed integers, with \( 0 \leq \delta \leq k \) and such that \( q \) is a prime power. Then

\[
C_q(n, k, k - \delta) \sim \frac{\left\lceil \frac{n}{k - \delta} \right\rceil}{q^{k - \delta}}.
\]

as \( n \to \infty \).

The proof of the theorem does not explicitly construct families of \( q \)-designs whose ratio with the covering bound approaches 1. The relationship between the best known \( q \)-covering designs and the covering bound is more complicated than in the case of Grassmannian codes, but it is usually the case that better ratios can be obtained by explicit constructions of \( q \)-covering designs when compared to the corresponding problem for Grassmannian codes. For example, a ratio of 1.05 can be obtained by explicit constructions \[^{8}\] when \( q = 2 \), \( k = 3 \), and \( \delta = 1 \), as \( n \to \infty \).

The asymptotics of \( A_q(n, 2\delta + 2, k) \) when \( n - k \) and \( \delta \) are fixed, and of \( C_q(n, k, r) \) when \( n - k \) and \( r \) are fixed, are also determined in this paper. The result for \( A_q(n, 2\delta + 2, k) \) is a simple corollary of Theorem 1, whereas the result for \( C_q(n, k, r) \) follows from results in finite geometry.

The rest of the paper is organized as follows. In Section \[^{II}\] we will present the proofs for our main theorems. In Section \[^{III}\] we consider the case when \( n - k \) is fixed as \( n \to \infty \). Finally, in Section \[^{IV}\] we provide comments on our results, and state some open questions.

**II. PROOFS OF THE MAIN THEOREMS**

We begin by observing a simple relationship between the minimum size of a \( q \)-covering design and the maximum size of a Grassmannian code.

**Proposition 1:** We have that

\[
A_q(n, 2\delta + 2, k) \geq C_q(n, k, k - \delta) \geq \frac{n}{k - \delta} - \frac{k}{n - k} A_q(n, 2\delta + 2, k)\]

and

\[
A_q(n, 2\delta + 2, k) \geq C_q(n, k, k - \delta) + \frac{n}{k - \delta} - \frac{k}{n - k} C_q(n, k, k - \delta).
\]

In particular, Theorems \[^{1}\] and \[^{2}\] are equivalent.

**Proof:** Let \( C \) be a Grassmannian code of size \( A_q(n, 2\delta + 2, k) \). There are exactly \( \left[ \frac{k}{k - \delta} \right] q \) subspaces of dimension \( k - \delta \) that lie in some element of \( C \), since no subspace of dimension \( k - \delta \) is contained in more than one element of \( C \). Thus there are \( \Upsilon = \left[ \frac{k}{k - \delta} \right] q - \left[ \frac{k}{k - \delta} \right] C_q(n, 2\delta + 2, k) \) uncovered subspaces of dimension \( k - \delta \), and we may construct a \( q \)-covering design by adding \( \Upsilon \) or fewer \( k \)-dimensional subspaces to \( C \). This establishes the first inequality of the proposition.

To establish the second inequality, let \( C \) be a \( q \)-covering design of size \( C_q(n, k, k - \delta) \). There are \( \left[ \frac{k}{k - \delta} \right] C_q(n, k, k - \delta) \) pairs \( (U, V) \) such that \( U \in G_q(n, k - \delta) \), \( V \in C \) and \( U \subseteq V \). Suppose we order these pairs in some way. Since every \( (k - \delta) \)-dimensional subspace \( U \) occurs at least once as the first element of a pair, there are \( \left[ \frac{k}{k - \delta} \right] C_q(n, k, k - \delta) - \left[ \frac{n}{k - \delta} \right] q \) pairs \( (U, V) \) where a pair \( (U, V') \) for some \( V' \in C \) occurs earlier in the ordering. Removing the corresponding subspaces \( V \) from \( C \) produces a Grassmannian code of size at least \( C_q(n, k, k - \delta) + \left[ \frac{n}{k - \delta} \right] q - \left[ \frac{k}{k - \delta} \right] q C_q(n, k, k - \delta) \), and so the second inequality follows.

Suppose Theorem \[^{1}\] holds. Let \( q \) be a fixed prime power, and let \( k \) and \( \delta \) be fixed integers such that \( 0 \leq \delta \leq k \). Then \(^{5}\) implies that \( \left[ \frac{n}{k - \delta} \right] - \left[ \frac{k}{k - \delta} \right] A_q(n, 2\delta + 2, k) = \)
\[ C_q(n, k, k - \delta) \leq A_q(n, 2\delta + 2, k) + o\left(\binom{n}{k-\delta} q\right) \]

and so the first inequality of the proposition implies

\[ C_q(n, k, k - \delta) \leq \frac{n}{k-\delta} q + o\left(\binom{n}{k-\delta} q\right) \text{ by (1)} \]

\[ \sim \frac{n}{k-\delta} q. \]

Theorem 2 now follows from this asymptotic inequality and the covering bound (3).

The proof that Theorem 1 follows from Theorem 2 is similar to the above, and is omitted.

We prove Theorem 1 by using a result in quasi-random hypergraphs. To state this result, we begin by recalling some terminology from hypergraph theory. A hypergraph \( \Gamma \) is \( \ell \)-uniform if all its hyperedges have cardinality \( \ell \). The degree \( \deg(u) \) of a vertex \( u \in \Gamma \) is the number of hyperedges containing \( u \); if \( \deg(u) = r \) for all \( u \in \Gamma \), we say that \( \Gamma \) is \( r \)-regular. The codegree \( \text{codeg}(u_1, u_2) \) of a pair of distinct vertices \( u_1, u_2 \in \Gamma \) is the number of hyperedges containing both \( u_1 \) and \( u_2 \). A matching (or edge packing) in \( \Gamma \) is a set of pairwise disjoint hyperedges of \( \Gamma \). We write \( U(\Gamma) \) for the minimum number of vertices left uncovered by a matching in \( \Gamma \). Thus the largest number of hyperedges in a matching of \( \Gamma \) on \( v \) vertices is \( (v - U(\Gamma))/\ell \). The main theorem we use is due to Vu [24, Theorem 1.2.1]:

**Theorem 3:** Let \( \ell \) be a fixed integer, where \( \ell \geq 4 \). Then there exist constants \( \alpha \) and \( \beta \) with the following property. Let \( \Gamma \) be an \( \ell \)-uniform \( r \)-regular hypergraph with \( v \) vertices. Define \( c = \max_{u_1, u_2} \text{codeg}(u_1, u_2) \), where the maximum is taken over all distinct vertices \( u_1, u_2 \in \Gamma \). Then

\[ U(\Gamma) \leq \alpha v (c/r)^{1/(\ell-1)} (\log r)^{\beta}. \]

The proof of Theorem 3 uses probabilistic methods, inspired by the techniques of Frankl and Rödl [13, 20]. See [2, 8, 19] for related work.

**Proof of Theorem 1:** If \( \delta = 0 \), then the set of all subspaces in the Grassmannian is a code that achieves the packing bound; if \( \delta = k \) then any single subspace of dimension \( k \) achieves the packing bound. So we may assume that \( 0 < \delta < k \). Now suppose that \( k = 2 \), so \( \delta = 1 \). The theorem follows in this case since it is known [12] that \( A_q(n, 4, 2) = \frac{q^2 - 1}{q^2 - 1} \) if \( n \) is even; and \( A_q(n, 4, 2) \geq \frac{q^2 - 1}{q^2 - 1} - \frac{1}{q^2 - 1} \) if \( n \) is odd. Thus we may suppose that \( k \geq 3 \).

Define a hypergraph \( \Gamma_n \), as follows. We identify the set of vertices of \( \Gamma_n \) with \( \mathbb{G}_q(n, k - \delta) \), and the set of hyperedges of \( \Gamma_n \) with \( \mathbb{G}_q(n, k) \). We define a hyperedge \( V \) to contain a vertex \( U \) if and only if \( U \subseteq V \) (as subspaces). We note that \( A_q(n, 2\delta + 2, k) \) is exactly the maximum size of a matching in \( \Gamma_n \).

Now \( \Gamma_n \) is an \( \ell \)-uniform hypergraph, where \( \ell = \binom{k-\delta}{k-\delta} q \). Note that \( \ell \geq 4 \), and \( \ell \) does not depend on \( n \). Every vertex of \( \Gamma_n \) has degree \( r(n) = \frac{n}{k-\delta} q \). Let \( U_1 \) and \( U_2 \) be distinct vertices, so \( \dim(U_1 + U_2) = k - \delta + i \) for some positive integer \( i \). Then \( \text{codeg}(U_1, U_2) \) is the number of \( k \)-dimensional subspaces containing \( U_1 + U_2 \), which is at most the number of \( k \)-dimensional subspaces containing a \((k - \delta + 1)\)-dimensional subspace of \( U_1 + U_2 \). So

\[ \text{codeg}(U_1, U_2) = \binom{n - (k - \delta + i)}{\delta - i} q \leq \binom{n - (k - \delta + 1)}{\delta - 1} q. \]

Thus \( U(\Gamma_n) = O\left(\frac{n}{k-\delta} q^{n/(\ell-1)} (\log r)^{\beta}\right) \).

Thus \( U(\Gamma_n) = \alpha\left(\binom{n}{k-\delta} q\right) \), and so the largest matching in \( \Gamma_n \) contains at least \( \frac{n}{k-\delta} q \) edges. The packing bound shows that the largest matching in \( \Gamma_n \) has size at most \( \frac{n}{k-\delta} q / \ell \), and so \( A_q(n, 2\delta + 2, k) \sim \frac{n}{k-\delta} q / \ell \), as required.

**Proof of Theorem 2:** Theorem 2 immediately follows from Proposition 1 and Theorem 1.

### III. The Case of Large \( k \)

In the previous section, we assumed that \( k \) is fixed (and therefore is small when compared to \( n \)). In this section, we consider the ‘dual’ case, where \( n - k \) is assumed to be fixed (and so \( k \) is large).

It is proved in [12, 16, 26] that \( A_q(n, 2\delta + 2, k) = A_q(n, 2\delta + 2, n - k) \). (This holds because taking the duals of all subspaces in an \((n, M, d, k)_q\) code in the Grassmann space produces an \((n, M, d, n - k)_q\) code.) Thus we have the following corollary of Theorem 1 which establishes the asymptotics of \( A_q(n, 2\delta + 2, k) \) when \( n - k \) and \( \delta \) are fixed with \( n \to \infty \).

**Corollary 1:** Let \( q \), \( t \) and \( \delta \) be fixed integers such that \( 0 \leq \delta \leq t \), and such that \( q \) is a prime power. Then

\[ A_q(n, 2\delta + 2, n - t) \sim \frac{\binom{n}{k-\delta} q}{\binom{n}{t-\delta} q} \] \hspace{1cm} (5)

as \( n \to \infty \).

Note that when \( \delta > t \) we have that \( A_q(n, 2\delta + 2, n - t) = A_q(n, 2\delta + 2, t) = 1 \), so the restriction on \( \delta \) in Corollary 1 is a natural one.

The same techniques do not establish a similar result for \( q \)-covering designs, since \( C_q(n, k, r) \) and \( C_q(n, n - k, r) \) are not equal in general. However, by translating some of the results known in finite geometry into our language, we can determine \( C_q(n, k, r) \) when \( q \), \( r \) and \( n - k \) are fixed, as Theorem 6 below shows.
For the proof of the theorem will need the notion of a $q$–Turán design. We say that $\mathbb{C} \subseteq \mathcal{G}_q(n, r)$ is a $q$–Turán design $\mathcal{T}_q(n, k, r)$ if each element of $\mathcal{G}_q(n, k)$ contains at least one element of $\mathbb{C}$. Let $\mathcal{T}_q(n, k, r)$ denote the minimum number of $r$-dimensional subspaces in a $q$-covering design $\mathcal{T}_q(n, k, r)$. The notions of $q$-covering designs and $q$-Turán designs are dual; the following result was proved in [13]:

**Theorem 4:** $C_q(n, k, r) = T_q(n, n - r, n - k)$ for all $1 \leq r \leq k \leq n$.

Using normal spreads [18] (also known as geometric spreads) Beutelspacher and Ueberberg [5] proved the following theorem using some of the theory of finite projective geometry.

**Theorem 5:** $T_q(vm + \delta, vm - v + 1 + \delta, m) = q^{vm - 1} / q^{m-1}$ for all $v \geq 2$ and $m \geq 2$.

We remark that Beutelspacher and Ueberberg show much more: that there is essentially only one optimal construction for a $q$-Turán design with these parameters.

As a consequence from Theorems 4 and 5 we obtain the following result for $q$-covering designs.

**Corollary 2:** Let $r$ and $n$ be positive integers such that $r + 1$ divides $n$. Then

$$C_q(n, n - n/(r + 1), r) = \frac{q^n - 1}{q^{n/(r+1)} - 1}.$$  

**Proof:** Theorems 4 and 5 (in the case when $\delta = 0$) show that

$$C_q(vm, vm - m, v - 1) = \frac{q^{vm} - 1}{q^m - 1}$$

for any integers $v \geq 2$ and $m \geq 2$. If we set $v = r + 1$ and $m = n/v$, the corollary follows except in the case when $n = 2$ and $r = 1$. But the corollary is true in this case also, as a $q$-covering design with these parameters must consist of all 1-dimensional subspaces.

**Theorem 6:** Let integers $q$, $t$ and $r$ be fixed, where $q$ is a prime power. For all sufficiently large integers $n$,

$$C_q(n, n - t, r) = \frac{q^{(r+1)t} - 1}{q^t - 1}.$$  

**Proof:** We first note that

$$C_q(n + 1, n + 1 - t, r) \leq C_q(n, n - t, r).$$  

(6)

This is proved in [13]. To see why (6) holds, fix a 1-dimensional subspace $K$ of an $(n + 1)$-dimensional vector space $V$. Let $\mathbb{C}$ be a $q$-covering design $C_q(n, n - t, r)$ contained in the $n$-dimensional space $V/K$. Then the set of subspaces $U$ such that $K \subseteq U \subseteq V$ and $U/K \in \mathbb{C}$ is a $q$-covering design $C_q(n + 1, n + 1 - t, r)$ containing at most $C_q(n, n - t, r)$ subspaces.

The inequality (6) implies that for any fixed $t$ and $r$, we have that $C_q(n, n - t, r)$ is a non-increasing sequence of positive integers as $n$ increases. So there exists a constant $c$ (depending only on $q$, $t$ and $r$) so that $C_q(n, n - t, r) = c$ whenever $n$ is sufficiently large. It remains to show that $c = (q^{(r+1)t} - 1)/(q^t - 1)$.

Set $n' = t(r+1)$, so $n' - t = n' - n'/r$. Corollary 2 implies that

$$c \leq C_q(n', n' - r, r) = \frac{q^{n'} - 1}{q^{n'/r+1} - 1} = \frac{q^{(r+1)n'} - 1}{q^r - 1}. $$

Now $c$ is bounded below by the Schönheim bound [4]. We give a simpler form for the Schönheim bound that holds for all sufficiently large $n$ as follows. When $n$ is sufficiently large we find that

$$\left[\frac{q^{n-r+1} - 1}{q^{n-r+1} - 1}\right] = q^r + 1 = \frac{q^t - 1}{q^t - 1}.$$  

Moreover, for $i$ such that $0 \leq i \leq r - 2$,

$$\left[\frac{q^{n-i} - 1}{q^{n-i} - 1}\left(\frac{q^{(r-i)t} - 1}{q^{r-i} - 1}\right)\right] = \frac{q^{(r-i)t} - 1}{q^t - 1}$$

provided that $n$ is sufficiently large. These equalities show that the right hand side of the Schönheim bound [4] is equal to $(q^{(r+1)t} - 1)/(q^t - 1)$ for all sufficiently large integers $n$. So $c \geq (q^{(r+1)t} - 1)/(q^t - 1)$, as required.

**IV. OPTIMAL CODES AND RESEARCH DIRECTIONS**

In this section, we comment on our results, we provide a little extra background, and we propose topics for further study.

We have proved that for a given $q$, if we fix $k$, and $\delta$, where $\delta < k$, the packing bound for Grassmannian codes is asymptotically attained when $n$ tends to infinity. We commented in Section II that the same is true when $q$ or $\delta$ grows. In Section III we determined the asymptotics of $A_q(n, 2\delta + 2, r)$ when $n - k$ and $\delta$ are fixed. These results do not address the cases when $q$ and $\delta$ are fixed, but $k$ and $n - k$ both grow (for example when $k = \lfloor \alpha n \rfloor$ for some fixed real number $\alpha \in (0, 1)$). Can similar results be obtained a wide range of these cases? When $k$ grows rather slowly when compared to $n$, it should be possible to use a result of Alon et al [2] to show that $A_q(n, 2\delta + 2, r)$ still approaches the packing bound.

The proof of Theorem II does not just give the leading term of $A_q(n, 2\delta + 2, k)$: the order of the error term is also given. However, we do not see any reason why this error term is tight.

Similar questions can be asked about the relationship between the covering bound and $C_q(n, k, r)$. It seems that small $q$-covering designs are easier to construct than large Grassmannian codes; certainly there are more construction methods currently known [8], [13].

As well as trivial cases, there are a few sets of parameters for which the exact (or almost the exact) values of $A_q(n, d, k)$ and $C_q(n, k, r)$ are known. Section III discusses a family of optimal $q$-covering designs. A family of optimal Grassmannian codes is known when $d = 2k$. Spreads (from projective geometry) give rise to optimal codes as well as $q$-covering designs when $k$ divides $n$. Known partial spreads of maximum size give rise to optimal codes in other cases [4], [6], [7], [14].
For small parameters, the best known codes are very often cyclic codes, which are defined as follows. Let \( \alpha \) be a primitive element of GF\((q^n)\). We say that a code \( \mathbb{C} \subseteq \mathbb{G}_q(n, k) \) is cyclic if it has the following property: whenever \( \{0, \alpha x^1, \alpha x^2, \ldots, \alpha x^m\} \) is a codeword of \( \mathbb{C} \), so is its cyclic shift \( \{\alpha x^1, \alpha x^2+1, \ldots, \alpha x^{m+1}\} \). In other words, if we map each subspace \( V \subseteq \mathbb{C} \) into the corresponding binary characteristic vector \( x_V = (x_0, x_1, \ldots, x_{q^n-2}) \) given by

\[
x_i = 1 \text{ if } \alpha^i \in V \quad \text{and} \quad x_i = 0 \text{ if } \alpha^i \notin V
\]

then the set of all such characteristic vectors is closed under cyclic shifts. It would be very interesting to find out whether cyclic codes approach the packing bound and the covering bound asymptotically. Again, in this case we would like to see proofs similar to the ones of Theorems 1 and 2. Of course, explicit families of asymptotically good cyclic codes would be even more worthwhile.

Acknowledgement

The authors would like to thank Simeon Ball for introducing to them the concept of normal spreads.
