**ABSTRACT**

**Aims:** *Vibrio harveyi* causes vibriosis to Asian seabass (*Lates calcarifer*). The disease spreads rapidly among fish stocked in the same cage. It causes high mortality especially in weak and small sized fish stocked at high density in poorly managed cages. Study to determine the virulence levels of the bacterial pathogen in various aquaculture animals is a key to prevent vibriosis in marine aquaculture.

**Methodology and Result:** Isolation of bacteria from diseased Asian seabass was done using tryptic soy agar (TSA) and thiosulphate citrate bile sucrose agar (TCBS) plates. Virulence of two strains of *Vibrio harveyi* (VHJR4 and VHJR7) was tested against clinically healthy aquaculture animals. The analysis revealed that the two bacterial strains differ in pathogenicity. The *V. harveyi* strain VHJR7 was virulent to Asian seabass at 1.40 × 10⁶ c.f.u. g⁻¹, humpback grouper (*Cromileptis altivelis*) at LD₅₀ 8.33 × 10⁵ c.f.u. g⁻¹ and black tiger shrimp (*Penaeus monodon*) at LD₅₀ 3.26 × 10⁶ c.f.u. g⁻¹, respectively. The *V. harveyi* strain VHJR4 was not virulent to Asian seabass and humpback grouper but it caused mortality to black tiger shrimp at LD₅₀ 1.32 × 10⁶ c.f.u. g⁻¹. Phenotypically, the two strains shared most of the biochemical features except that the *V. harveyi* strain VHJR7 was a urease positive and grew at 8.5 % NaCl, and at 10 °C. The percentage similarity of nucleotide sequences of 16S rDNA in *V. harveyi* VHJR4 and *V. harveyi* VHJR7 was higher (99 %) but reduced at 95 % in hemolysin gene.

**Conclusion, significance and impact of study:** Pathogenic strain of *V. harveyi* causes mortality and affects aquaculture production of Asian seabass. Hence, vaccine development against the bacterial pathogen is urgently needed for sustainability of Asian seabass aquaculture in Malaysia.

Keywords: *Vibrio harveyi*, virulence, Asian seabass, vibriosis

**INTRODUCTION**

*Vibrio harveyi* is a Gram-negative bacterium, ubiquitous in the marine environments and usually found free-living in the water column, and in the gut of some marine animals. The bacterium is a causative agent of vibriosis that capable of infecting wide range of aquatic animals including penaeids (Liu et al., 1996; Abraham et al., 1997; Alvarez et al., 1998; Robertson et al., 1998), sea horse (Tendencia, 2004), bivalves (Pass et al., 1987), cephalopods (Ramesh et al., 1999), marine teleosts (Yi et al., 1997; Soffientino et al., 1999; Zhang & Austin 2000; Thompson et al., 2002; Tendencia, 2002) and elasmobranchs (Grimes et al., 1984). *V. harveyi* caused chronic skin ulcer in shark (Bertone et al., 1996), gastro-enteritis in cultured groupers (Yi et al., 1997; Lee et al., 2002), red drum (Liu et al., 2003), and cultured cobia (Liu et al., 2004). The bacterium was also reported to cause deep dermal lesions in wild specimens of jack crevalle (Krakberger-Beatty et al., 1990). In addition, it caused mortalities in farmed sole (Zorrilla et al., 2003), cultured brown spotted grouper and silver black porgy (Saeed, 1995), and cage cultured grouper (Qin et al., 2006). It caused eye lesions in milkfish (Ishimaru & Muroga, 1997), common snook (Kraxberger-Beatty et al., 1990), and sunfish (Hispano et al., 1997). In cultured Asian seabass (*Lates calcarifer*), however, the bacterium causes vibriosis that is characterized by anorexia, darkening of the whole fish, local hemorrhagic ulcers on the mouth or skin surface, tail and fin rot, focal necrotic lesions in the muscle and swollen intestine, and eye opacity (Tendencia, 2002; Ransangan & Mustafa, 2009). The virulence of *V. harveyi* is reported dependent on host species (Vera et al., 1999), doses, time exposure and age of host species (Jun & Huai-shu, 1998), and pathogenic factors of the bacterial strains (Gomez-Gill et al., 1998).

This paper describes the virulence of two strains of *V. harveyi* isolated from diseased Asian seabass cultured in the open net cages installed in coastal waters of Sabah, Malaysia to Asian sea bass (*Lates calcarifer*), humpback grouper (*Cromileptis altivelis*) and black tiger shrimp.

MATERIALS AND METHODS

**Bacterial characterization**

Two strains of *V. harveyi* designated as VHJR4 and VHJR7 isolated from diseased Asian seabass, *Lates calcarifer* (Bloch) cultured in open net cages in Sabah, Malaysia during the vibriosis outbreak in February 2008 (Ransangan & Mustafa, 2009) were used in this study. These strains were isolated from head kidney and heart of diseased seabass (weighing 5-7g, water temperature 28 °C) using tryptic soy agar (Difco, Detroit, MI; supplemented with 2 % NaCl; TSA) and/or thiosulphate citrate bile salt sucrose agar (TCBS, Difco) plates. The pure cultures were stored in tryptic soy broth (Difco; +2 % NaCl; 25 % glycerol) at -86 °C. Subsequently, the bacteria were characterized using the standard biochemical method as described by Alsina & Blanch (1994) and identified using 16S rRNA and hemolysin gene sequencing. For the temperature tolerance test, each bacterial isolate was incubated at 5, 10, 12, 15, 20, 25, 30, 35, 37 and 40 °C. Tolerance to NaCl was determined for 0, 0.5, 3, 4, 5, 6, 8, 8.5, 9.0 and 10 % (w/v) NaCl in tryptic soy broth. Hemolytic activity of the bacterial strains was tested against tilapia and cow bloods. All the tests were performed in triplicate at 28 °C and incubated for 24 h. The reactions were compared with a reference strain of *V. carchariae* (VHJR7) isolated from diseased Asian seabass, *Lates calcarifer* (Grimes et al., 1984) and *V. harveyi* (VHJR4) from diseased Asian seabass. The origin of each bacterial strain used in this study is shown in Table 1.

**Isolation of genomic DNA**

Genomic DNA from all bacterial strains was extracted using the proteinase K extraction method. Briefly, the bacteria were incubated in sterile 5ml TSB (Difco, Becton Dickinson, Maryland, USA) and incubated at 28 °C overnight. Bacterial cells were collected from 1.0 ml of the bacterial suspension by centrifugation at 9,000 rpm for 10 min at 4 °C. The bacterial cells were incubated with lysis buffer (600 µl 1x TE buffer, 30 µl of 10 % SDS (w/v) and 3 µl of 20 mg/ml proteinase K (Sigma)) at 37 °C for 1 h after which the mixture was added with 100µl of CTAB/NaCl of solution and further incubated at 65 °C for 10 min. Subsequently, the mixture was treated with equal volume of chloroform:isoamylalcohol (24:1), and precipitated by centrifugation at 9,000 rpm for 10 min at 4 °C. Then, 600 µl of the aqueous phase was carefully transferred to a fresh microfuge tube with equal volumes of phenol: chloroform: isoamylalcohol (25:24:1) and centrifuged at 8,000 rpm for 10 min at 4 °C. Thereafter, DNA pellet was precipitated from 500 µl of aqueous phase using equal volume of chilled isopropanol and centrifuged at 13,000 rpm for 15 min at 4 °C. Finally, the DNA pellet was washed with 1.0 ml of chilled 70 % ethanol and dried briefly before dissolving into 50 µl 1X TE buffer. The concentration of the extracted DNA was determined using GeneQuant™ RNA/DNA calculator.

**PCR amplification, cloning and sequencing**

The total genomic DNA extracted from all bacterial strains was amplified for 16S ribosomal RNA and hemolysin genes. The partial sequence of 16S rDNA was amplified using PCR primers designed based on the partial 16S rDNA sequence (Q370528) of *Vibrio harveyi* ATCC 35084. The forward (3F: CCTGAAGTGGGGGATAACC) and reverse (2R: ACGTCGTCCCCACCTTCCTC) primers were designed from nucleotides 2-20 and 1061-1042, respectively. The hemolysin gene was amplified using PCR primers (VHFR2: ACGACGAATACAATCTCTGG and VHFR3: GAGGACGTTTGGTGAGATAA) described by Zhang et al. (2001). The PCR amplifications for both genes were conducted in 25 µl total reaction (12.5 µl of PCR Master Mix (Promega, Madison, Wisconsin), 1.0 µl of each 10 µM forward and reverse primers, 1.0 µl DNA template (0.307 µg/µl) and 9.5 µl nuclease-free water). The PCR amplification was carried out one cycle at 95 °C for 3 min, 30 cycles at 95 °C for 1 min, 58 °C for 1 min and at 72 °C for 1 min, and finally one cycle at 72 °C for 5 min. PCR products were purified using AccuPrep™ PCR purification Kit (Bioneer Corporation, Seoul, Korea) according to the manufacturer’s instruction. Two microtitre (2.0 µl) of the PCR product was cloned using pGEM™-T Easy (Promega) cloning vector as prescribed by the manufacturer’s manual. The plasmid was purified using PureLink™ Quick Plasmid Miniprep Kit (Invitrogen) following the manufacturer’s instructions. Finally, 20 µl of the purified plasmid harbouring DNA inserts as determined by EcoR1 digestion analysis was sequenced using M13 forward and reverse primers (Macrogen, DNA sequencing service, Seoul, Korea). The nucleotide sequences of the 16S rDNA and hemolysin gene were further analyzed by using DNASTAR (Windows version 5.05, Wisconsin, USA) for the construction of phylogenetic tree and the calculation of percentage of identity.

**Antibiotic Sensitivity Assay**

Stock cultures of the bacterial strains (VHJR4 and VHJR7) were grown on TSA for 24 h at 28 °C. The bacteria were
Figure 1: Phylogenetic tree based on 37 nucleotide sequences (890bp) and 35 nucleotide sequences (1257bp) of 16S ribosomal DNA (left) and hemolysin (right) genes, respectively, of *Vibrio* species. This tree was constructed by using the Clustal W method in the MegAlign package, DNASTAR Ver. 5.05, Wisconsin, USA.

suspended in sterile phosphate buffered saline (PBS: 0.8775 % NaCl, 0.02 % KCl, 0.02 % KH₂PO₄, 0.115 % Na₂HPO₄, 10 % glycerol, pH 7.2) and diluted to a turbidity equivalent to a MacFarland No. 0.5 standard solution (0.5 ml BaSO₄ + 99.5 ml 0.36 % N HCl). The bacterial suspension (0.1 ml) was spread onto Mueller-Hinton agar (Difco) and antibiotic discs then added as described by Koneman et al. (1988). The antibiotics discs (Oxoid) used in the assay included ampicillin (10 µg), chloramphenicol (30 µg), ciprofloxacin (5 µg), furazolidone (100µg), kanamycin (30 µg), nalidixic acid (3 µg), neomycin (10µg), nitrofurantoin (300 µg), novobiocin (6 µg), oxolinic acid (2 µg), oxytetracycline (30 µg), penicillin G (10 units), streptomycin (25 µg), sulphamethoxazole (100µg), tetracycline (10 µg) and vancomycin (30 µg). The plates were incubated at 35 °C for 18 h and inhibition zones were measured using a graduated ruler (0.5 mm), and the average result was recorded to the nearest millimeter.

**Fish and virulence tests**

Asian seabass (Lates calcarifer), humpback grouper (Cromileptis altivelis) and black tiger shrimp (Penaeus monodon) weighing 5-7 g in total body weight were held in tanks (1000L) supplied with aerated 29 ppt seawater at 28-29 °C. The two bacterial strains (VHJR4 and VHJR7) were selected for virulence tests. The lethal dose-50 % end point (LD₅₀) tests, with batches of 20 animals per dose, were conducted by intraperitoneal (i.p) injection in seabass and humpback grouper, and intramuscular (i.m) injection at the 5th abdominal segment in black tiger shrimp with 24 h bacterial suspension (10⁻⁴-10⁻⁶ c.f.u. animal⁻¹) into the test animals (Trevors and Lusty, 1985). Sterile PBS was injected into other groups of animals as parallel controls. The LD₅₀ values were calculated using the method of Reed & Muench (1938). Mortalities were recorded daily for 11 days post challenge. Reisolation and identification of the bacteria from kidney of moribund animals after bacterial challenge were conducted by using TSA and TCBS agar plates.

**RESULTS**

**Bacterial characterization**

All bacterial strains examined in this study were glucose fermentative, non-motile, oxidase and catalase positive. They recorded negative in Vogues-Proskauer, citrate utilization, arginine dehydrogenase, phenylalanine agar, and β-galactosidase tests but positive in lysine decarboxylase, methyl red and indole production tests. Two bacterial strains (VHJR7 and ATCC 35084) were able to utilize urea while VHJR4 was not. All bacterial strains produced acid from carbohydrates fermentation test (D-fructose, D-glucose, D-galactose, D-mannose, D-xylitol, D-sacrose, D-maltose, D-mannitol and D-galactose) but no gas produced. However, no acid was produced from other carbohydrates such as D-lactose, D-salicin, D-raffinose, and L-rhamnose (Table 2). All bacterial strains grew well on TCBS agar with yellow colonies. All the organisms grew at 12-37 °C, but not at 5, and 40 °C. However, V. harveyi (ATCC 35084) and (VHJR7) grew at 10 °C. All bacterial strains grew well in 0.5-8 % (w/v) sodium chloride but not in 0 % and 10 %, respectively. The V. harveyi ATCC 35084 grew at 8.5 % and 9.0 % (w/v) sodium chloride whereas V. harveyi VHJR7 grew only at 8.5 % but not at 9 %. All bacteria were able to utilize 10 % gelatin and produced β-hemolytic activity on both tilapia and cow blood agars.

**Figure 2:** Average survival percentage of Asian seabass (L. calcarifer) challenged with V. harveyi strain VHJR7 (upper) and VHJR4 (lower). ● fish challenged with 5.0 x 10⁶ c.f.u. fish⁻¹; □ fish challenged with 5.0 x 10⁵ c.f.u. fish⁻¹; △ fish challenged with 5.0 x 10⁴ c.f.u. fish⁻¹; ■ fish challenged with 5.0 x 10³ c.f.u. fish⁻¹; ▲ fish challenged with 5.0 x 10² c.f.u. fish⁻¹; ● fish challenged with sterile PBS.

**Nucleotide sequencing analysis**

The PCR amplifications of 16S rDNA from the two bacterial strains (VHJR4 and VHJR7) were successfully carried out using PCR primers designed in the study. The PCR products (1060bp) of 16S rDNA from the two bacterial strains were successfully cloned into pGEM-T Easy Cloning vector and sequenced. The partial sequences of 16S rDNA were made available in the

sequences of 16S rDNA were made available in the GenBank with accession numbers DQ995238 and DQ991206, respectively. Although the nucleotide sequence analysis of the 16S rDNA fragments (nt100-990nt of *V. harveyi* ATCC 35084 (GQ370528)) from the two bacteria revealed high percentage of identity (>99.9) to 16S rDNA nucleotide sequences belonging to *V. harveyi*, they were also showed high similarity (94-99.8 %) to other *Vibrio* species (Figure 1).

The complete coding sequences (1.3kb) of hemolysin gene from the bacterial strains (VHJR4 and VHJR7) were also successfully cloned and sequenced. The nucleotide sequences were then deposited in GenBank with the accession numbers GQ120526 and EU862239, respectively. Although the nucleotide sequence analysis of hemolysin gene (nt65-nt1321 of *V. harveyi* ATCC 35084 (GQ149070)) in VHJR7 revealed high percentage of identity (>99 %) to *V. harveyi*, the VHJR4 showed a reduced (94.0-95.4 %) identity. However, the nucleotide sequences from both bacterial strains showed lowered percentage of similarities when compared to other closely related *Vibrio* species such as *V. alginolyticus* (84.6 %), *V. campbellii* (78.9-79.2 %) and *V. parahaemolyticus* (77.1-77.9 %). On the basis of sequencing results, the two bacterial strains examined in this study were identified as *V. harveyi*.

Antibiotic susceptibility assay

The antibiotic susceptibility assay (Table 3) revealed that the two *V. harveyi* strains (VHJR4 and VHJR7) were sensitive to chloramphenicol, ciprofloxacin, furazolidone, nalidixic acid, nitrofurantoin, oxolinic acid oxytetracycline, streptomycin, sulphamethoxazole and trimethoprim. Both strains showed intermediate reaction to kanamycin, novobiocin and tetracycline. However, they were resistant to ampicilin, neomycin, penicillin and vancomycin.

Virulence assays

When the virulence of the two *V. harveyi* strains (VHJR4 and VHJR7) was evaluated, it was found that *V. harveyi* VHJR7 highly virulent to seabass at LD<sub>50</sub> 1.40 x 10<sup>4</sup> c.f.u. g<sup>-1</sup> fish (Figure 2), humpback grouper at LD<sub>50</sub> 8.33 x 10<sup>3</sup> c.f.u. g<sup>-1</sup> fish (Figure 3) and to black tiger shrimp at LD<sub>50</sub> 3.26 x 10<sup>4</sup> c.f.u. g<sup>-1</sup> shrimp (Figure 4). Although *V. harveyi* VHJR4 did not produce mortality to seabass and humpback grouper (Figure 2 and 3; Table 4), it caused mortality to shrimp at LD<sub>50</sub> 1.32 x 10<sup>6</sup> c.f.u. g<sup>-1</sup> shrimp (Figure 4 and Table 4). Pure cultures of bacteria as homologous colonies were recovered from the kidney of the moribund fish and hepatopancreas of shrimp after bacterial challenge and identified as the same species. No mortality was observed in the controls injected with sterile PBS.

DISCUSSION

The isolation of *V. harveyi* from diseased seabass in the present study is not surprising as the bacterial pathogen has been isolated in a number of diseased marine animals including Asian seabass (Tendencia, 2002), abalone (Nishimori et al., 1998; Nicolas et al., 2002), groupers (Rasheed, 1989; Yii et al., 1997), shrimps (Jiravanichpaisal et al., 1994; Vandenberghe et al., 1998), red drum (Liu et al., 2003) and sharks (Grimes et al., 1984). Although *V. harveyi* caused gastroenteritis in
Although 16S rDNA sequencing has been proven useful with 5.0 x 10^6 opacity in the Asian seabass (Ransangan & Mustafa, 2004), it was reported to cause deep skin lesions, seabream (Liu et al., 1996) and cobia (Liu et al., 2004), it was reported to cause deep skin lesions, hemorrhagic of fin base and anus, tail and fin rot, and eye opacity in the Asian seabass (Ransangan & Mustafa, 2009).

Because V. harveyi has been known to be phenotypically heterogenous (Grimes et al., 1993; Alsina and Blanch, 1994; Vandenberghe et al., 2003) and reported to contain mobile genetic elements such as bacteriophages (Oakley & Owens, 2000) that often contribute new phenotypic characteristics (Munro et al., 2003), the biochemical and/or physiological tests cannot precisely identify the pathogen (Vandenberghe et al., 2003). This appears to be the case in the present study.

Although 16S rDNA sequencing has been proven useful for classification and identification of bacterial species (Kolbert & Persing, 1999), the finding of this study shows that high percentage of similarity (>94 %) of nucleotide sequences of the 16S rDNA in both strains of V. harveyi (VHJR4 and VHJR7) compared to their closely related species may not be sufficient to correctly identify the two bacteria into species level. In the past, similar findings were also reported by several authors (Gomez-Gil et al., 2004; Chiang et al., 2006).

Figure 3: Average survival percentage of humpback grouper (C. altivelis) challenged with V. harveyi strain VHJR7 (upper) and VHJR4 (lower). ◆ fish challenged with 5.0 x 10^6 c.f.u. fish; □ fish challenged with 5.0 x 10^5 c.f.u. fish; △ fish challenged with 5.0 x 10^4 c.f.u. fish; ■ fish challenged with 5.0 x 10^3 c.f.u. fish; ▲ fish challenged with 5.0 x 10^2 c.f.u. fish; ● fish challenged with sterile PBS.

Sequence of hemolysin gene has been used in the identification of closely related Vibrio species (Conejero & Hedreyda, 2004). In the present study, the result from sequencing of hemolysin gene has clearly shown that the two bacterial strains examined are highly identical to V. harveyi than to other closely related species such as V. alginolyticus, V. campbellii and V. paraahaemolyticus.

V. harveyi strain VHJR7 was shown to be highly virulent to seabass, with average LD_{50} of 1.40 x 10^3 c.f.u. g^{-1} fish. It is also virulent to humpback grouper and black tiger shrimp with average LD_{50} of 8.33 x 10^4 c.f.u. g^{-1} fish and association of V. harveyi in diseased marine animals with 3.26 x 10^4 c.f.u. g^{-1} shrimp, respectively. This is not a surprising finding as many studies have reported the
Table 4: LD_{50} values of the two V. harveyi strains against Asian seabass (Lates calcarifer), humpback grouper (C. altivelis) and black tiger shrimp (Penaeus monodon).

| Fish Samples | Bacterial Samples | Dose (c.f.u. g^{-1} body weight) | Mortality (%) | LD_{50} Value (c.f.u. g^{-1} body weight) |

Different virulence levels. Previous challenge studies involving V. harveyi found that the pathogen produced LD_{50} values higher than 2 x 10^7 cfu g^{-1} in grouper (Yii et al., 1997) and in red drum (Liu et al., 2003). In the study by Saeed (1995), he has reported that V. harveyi produced 50% mortality to silvery black porgy (Acanthopagrus cuvieri) and brown spotted grouper (Epinephelus tauvina) at 4.90±0.2 x 10^7 c.f.u fish and 1.56±0.19 x 10^6c.f.u fish, respectively. However, virulence study by Liu et al. (2004) revealed that V. harveyi strain c3d1 was highly virulent to cobia at LD_{50} 7.48 x 10^7 c.f.u g^{-1} which is in agreement with the present finding. V. harveyi isolated from diseased marine fishes were also reported virulent to the olive flounder (Paralichthys olivaceus) and black rockfish (Sebastes schlegeli) with LD_{50} of 2.48 x 10^7-8.76 x 10^6 and 2.0 x 10^5-2.52 x 10^6 cfu g^{-1} fish, respectively (Won and Park, 2008). Also, Zhang and Austin (2000) found that V. harveyi (VIB 654, VIB 571 and VIB 572) were virulent to rainbow trout and Atlantic salmon with LD_{50} ranged from 2.51 x 10^5 to 5.32 x 10^5 cells/fish. In contrast, the V. harveyi strain VHJR4 in this study was not virulent to seabass and humpback grouper but it was slightly virulent to black tiger shrimp with LD_{50} 1.32 x 10^6 cell/shrimp. The difference in the virulence levels of V. harveyi reported in this study with previous studies revealed that pathogenicity of V. harveyi is dependent on species (Vera et al., 1992), doses used, time of exposure and age of challenged animals (Jun & Huai-shu, 1998), and the pathogenic factors of the strains employed (Gomez-Gill et al., 1998).

Some studies indicated that virulence factors in V. harveyi can be contributed from toxins that either having protease or hemolysin activities (Fukasawa et al., 1989; Liu et al., 1997; Svitil et al., 1997; Zhang & Austin 2000; Zhang et al., 2001; Liu and Lee., 1999). Other studies, however, have shown that the pathogenicity of V. harveyi was derived from phage in which genes coding for toxin production were acquired by gene transduction (Morris & Robert, 1995). In addition, a phage infecting V. harveyi named VHML (Vibrio harveyi Mio-virus like) has been isolated by several authors (Ruangpan et al., 1999; Oakey.
Although the development of vaccine against species. In the past, colony forming unit. In contrast, the pathogenicity of sensing since the pathogen is capable of producing related to gene transduction in nature rather than quorum level are already showing some interesting results (Zhu still at the preliminary stage, experiments at laboratory hydrolysing activity in hydrolysing activity was reported to cause gastroenteritis however, requires further investigation.

The urea-hydrolysing activity may potentially be used as a marker in determining pathogenicity within the Vibrio species. In the past, V. parahaemolyticus having urea-hydrolysing activity was reported to cause gastroenteritis in human (Kaysner et al., 1994). The occurrence of urea-hydrolysing activity in V. harveyi VHJR7 which was virulent to both fish and shrimp in the present study, however, requires further investigation.

Results from the antibiotic susceptibility tests against the two strains of V. harveyi examined in this study revealed that they were resistant to ampicillin, penicillin G and vancomycin. However, they were found sensitive to chloramphenicol, ciprofloxacin, nalidixic acid, nitrofurantoin, oxolinic acid and oxytetracycline. Because prolonged usage of antibiotics may cause bacterial pathogens to develop resistance (Miranda & Zemelman, 1999; Bernd et al., 2001; Costi et al., 2002). The fact that the V. harveyi VHJR4 is not virulent to fish, it can have the advantages to be developed into live vaccine against vibriosis in marine fish aquaculture in the future.

CONCLUSION
Pathogenic strain of V. harveyi causes mortality and affects aquaculture production of Asian seabass. Hence, vaccine development against the bacterial pathogen is urgently needed for the sake of sustainability of Asian seabass aquaculture in Malaysia.

ACKNOWLEDGEMENTS
The authors express special thank to the Department of Fisheries, Sabah for providing experimental animals. This work was funded by the Centre of Research and Innovation, Universiti Malaysia Sabah under the research grant no. FRGS-44.
