Abstract
Edible bird nest (EBN) mainly comprises a secretion of the salivary gland of different Swiftlet species has been used as a symbol of wealth and power as well as a crucial ingredient in traditional Chinese Medicine. The MTT assay and flow cytometry analysis were carried out to evaluate the effect of EBN extract in treated Influenza A virus infected MDCK cells. MTT assay was performed to determine the cell viability and Ha assay was used to determine the virus titer after 24 hour of post treatment with EBN extract towards MDCK cells challenged with influenza A virus. The results showed that there was a significant increase in cell viability (p<0.05) of EBN extract treatment compared to positive infected control. Annexin V-fic double staining method was carried out to identify the mode of cell death in MDCK cells by calculating the means of each apoptosis stage. The results showed that there was a significant reduced early apoptotic injury in infected cells treated with EBN extract. In summary, the current finding suggests that EBN may be have the potentiality to be as an apoptotic inhibitor and ameliorate the infected cells caused by virus.

Introduction
Apoptosis is an important physiological necessar, iny for development and maintenance of tissues homeostasis including tissue atrophy, the immune system development and biological tumor [1,2]. It also plays an important function in the pathogenesis of many infectious diseases including those caused by viruses [3-5]. Many virus infections result in apoptosis of host cells, and several viruses have evolved mechanisms to inhibit apoptosis. Influenza viruses induce apoptosis through mechanism then both cellular and viral factors depending on the cell type. However, the precise mechanism still remain unclear.

Edible bird nest (EBN) is natural food product made from Aerodramus genus Swiftlet’s saliva. Studies have shown that this animal saliva previously found to contain bioactive compounds that are powered with anti-apoptotic and anti-oxidant properties [6,7]. As apoptosis have been suggested as crucial events in Influenza virus infection, EBN, the salivary secretion of swiftlets, may have anti-apoptosis relevance in the therapeutic context of viral infection. Hence, this study aimed to investigate the anti-apoptosis effect of EBN.

Materials and methods
Preparation of EBN extracts
Raw EBN from the swiftlet of Aerodramus genus collected from bird’s nest house in Teluk Intan, Perak, Malaysia. The cleaning process was carried out by first soaking after the unprocessed EBN in distilled water until softened. Debris and feathers were removed after which the EBN was subjected to drying process at 70ºC for 16 hrs and followed by grounding and sifting through a mesh (60 µM in pore size). The grounded samples were kept in distilled water at 3ºC in about 16 hours and continued heated for 30-60 min at 60ºC. The extract was then filtered and freeze-dried after 48 hours freezing at -80ºC, and stored for the future use.

Madin darby canine kidney (MDCK) cell culture
MDCK cell line was purchased from the American Type Culture Collection (ATCC®,CCL-34™) and grown in Dulbecco’s Modified Eagle’s Medium (Gibco,UK) supplemented with 10% fetal bovine serum (Gibco,UK), antibiotic-antimycotic (Gibco,UK). The cells then were seeded into a sterile 96-well flat bottom plate (Nunc, USA) and maintained at 37°C humidified incubator with 5% CO2 (Galaxy,UK) for 2-3 days until 70%-80% confluency is achieved.

Virus propagation
Influenza A virus, strain A/Puerto Rico/1934 (H1N1) was purchased from the American Type Culture Collection (ATCC®, VR-95™) and propagated in MDCK cells, then the stock virus was titrated by TCID50. In obtained 100 TCID50, the resultant virus titer was further diluted with 100 µl taken from the amount of TCID50, then it was to be used as a constant positive control in the following procedure.

Cell viability based on combination treatment

This procedure was performed by using Maximal Non-Cytotoxic Concentration of EBN and constant virus titer (100 TCID\textsubscript{50}). Briefly, the virus was first inoculated into the MDCK cells and later followed by the EBN extract replacement for 1 hr followed by change with media. All the samples were incubated at 37°C in 5% CO\textsubscript{2} incubator.

After 24 hour of post-treatment incubation, the plates were exposed to the MTT assay. Treated cells were subjected to MTT reagent (Sigma Aldrich, USA) in which reacts to quantify the viable cells. After 2-3 hr exposure to the MTT reagent to solubilise the formazan precipitation. Absorbance of the solution was measured espectrophotometrically by using ELISA reader at 540nm wavelength (Bio Tek Instruments EL800,USA).

Apoptotic cells analysis

The protocol of Annexin V-FITC Apoptosis Detection Kit (BD Pharmingen, USA) by Riger \textit{et al.} was performed in this procedure\cite{8}. Briefly, upon completion of treatments, cells were harvested and washed with binding buffer. Then, Annexin V and propidium iodide (PI) were added and incubated in dark for 15 min. Subsequently, washing was performed twice with binding buffer which then incubated for 15 min at 37°C. Finally, the samples were reads for analysis with Becton Dickson FACS Calibur Flow Cytometer (BD Biosciences, USA).

Statistical analysis

Data was collected as triplicate for each experiments. The results were expressed as mean ± standard deviation. Statistical significance was assessed with Anova test and P value <0.05 was considered significant.

Results and discussion

Cytotoxic profile of Edible Bird Nest (EBN) extract

Toxicity study was first performed with addition of EBN extract to MDCK cells to determine the concentration side effect as well as MNCCs of the extract on cultured cells. MNCC is maximal non-cytotoxic concentration of the EBN extract.

Based on the figure 1, cytotoxicity percentage in MDCK cells showed an increasing trend of optimal density (OD) of cell viabilities along the concentration. As determined from the bar graph, MNCCs was 12.5 mg/ml.

In fact, compared to solubility and stability are major factors that contribute to varied activities in different extracts\cite{9}.

EBN extracts improves cell viability in H1N1 virus-challenged MDCK cells

The MTT was performed in order to quantify the cell viability based on the apoptotic reduction activity. Upon challenged with 100TCID\textsubscript{50} H1N1 virus for 24 hour post treatment with EBN extract, cell viability increased to about 20% of that of infected control (Figure 2). Meanwhile, the EBN alone treatment generally did not effect the infected group. This could be due to the mitogenic property of EBN that promoted cell growth, as made evident a study by Zainal Abidin \textit{et al.} Which shows that EBN promoted cell division in rabbit corneal keratocytes\cite{10}.

EBN extracts reduce early apoptotic event in H1N1 virus-challenged MDCK cells

Apoptotic cells resulted due to phosphatidylserine (PS) translocation towards the outer leaflet of the plasma membrane caused the apoptotic or death cells and membrane integrity become loss. Therefore, the annexin V-FITC double staining was performed in this study to calculate the percentage of cell death in different stages of apoptosis. In this assay, cells residing at different level of apoptosis upon exposure to the virus infection (A/Puerto Rico/8/1934 (H1N1)) by differential staining of DNA and also PS, whereby cells are grouped and revealed in dot plot. Annexin V-FITC/PI (lower left quadrant) are classified as healthy cells, the cells that are considered early apoptotic showed Annexin V-FITC+/PI\textsuperscript{-} (upper rightquadrant), whereas late apoptotic (upper rightquadrant) represent as Annexin V-FITC+/PI\textsuperscript{-} as well as necrotic (upper leftquadrant).

Based on the result, in general, EBN treatment MDCK cells alone did not stimulate apoptotic injury and also reduced the cell death population (Figure 3B). Most of the infected MDCK cells-treated undergo significant in reduced apoptosis when compared to infected control (Figure 3A). Meanwhile at 24 hour of post treatment, there was prominent significant reduced early apoptosis in EBN extract whilst reduced late apoptosis but less effectively compared to Oseltamivir treatment (Figure 3C,3D). Thus, the finding is correlated with the previous research, whereas the cells shown the cell death reduction in the early stage of apoptosis\cite{11,12}.

Figure 1. The MNCC value for EBN concentration. Asterisk (*) show the first non-significant difference of the cytotoxicity with with (p<0.05) cytotoxicity with (p<0.05) following Tukey HSD post hoc analysis.

Figure 2. Effect of combination treatment on strain A/Puerto Rico/8/1934 (H1N1)-challenged MDCK cell viability.

Cell viability was assessed with MTT assay and data shown are means ± SD by Tukey HSD pairwise comparison between groups (p<0.05). *\textsuperscript{x} Values with different superscript differ significantly difference with infected group (PR8) (p<0.05) indicated by caret (*).
Conclusion

It has been successfully demonstrated that EBN extracts confer apoptotic protection in H1N1-challenged MDCK cells. Particularly, EBN demonstrated apoptotic protection potential by improving cell viability. Thus, it can be concluded that EBN extracts shown to inhibit apoptosis.

Acknowledgement

Our sincere gratitude to Dr. Fadzillah A’ini, from Department of Veterinary Services, Putrajaya, Malaysia, who kindly provided EBN sample. This project was supported by Coe Swiftlet grants no.6371400 from Ministry of Agriculture, Putrajaya, Malaysia.
