February 8, 2023

Abstract

Let $S(\rho)$ be the von Neumann entropy of a density matrix $\rho$. Weak monotonicity asserts that $S(\rho_{AB}) - S(\rho_A) + S(\rho_{BC}) - S(\rho_C) \geq 0$ for any tripartite density matrix $\rho_{ABC}$, a fact that is equivalent to the strong subadditivity of entropy. We prove an operator inequality, which, upon taking an expectation value with respect to the state $\rho_{ABC}$, reduces to the weak monotonicity inequality. Generalizations of this inequality to the one involving two independent density matrices, as well as their Rényi-generalizations, are also presented.

1 Introduction

In quantum mechanics, the notion of conditional probability is generally ill-defined. For example, consider an EPR pair over two qubits. The density matrix of a qubit is maximally mixed but the global state is pure. Thus, the entropy of the global state is strictly smaller than the entropy of its marginal. Examples like this show that one cannot generally ensure $S(\rho_{AB}) - S(\rho_B) \geq 0$, where $S(\rho) := -\text{Tr}(\rho \log \rho)$ is the von Neumann entropy of a density matrix $\rho$. Nevertheless, the following inequality is still true:

$$S(\rho_{AB}) - S(\rho_A) + S(\rho_{BC}) - S(\rho_C) \geq 0.$$ (1)

This inequality is known as the weak monotonicity in the literature. We note that weak monotonicity is equivalent to the strong subadditivity of entropy [1], a fact that can be shown by considering a purification of $\rho_{ABC}$.

In this paper, we prove operator extensions of Eq. (1). Consider a tripartite system $\mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C$. For any positive definite density matrix $\rho_{ABC}$, we show that

$$\log \rho_{AB} - \log \rho_A + \log \rho_{BC} - \log \rho_C \leq 0,$$ (2)

where a tensor product with the identity operator is suppressed for notational convenience. For instance, $\log \rho_{AB}$ is a short-hand notation for $\log \rho_{AB} \otimes I_C$, where $I_C$ is the identity acting on $\mathcal{H}_C$. Note that, by taking the expectation value with respect to $\rho_{ABC}$, Eq. (1) is recovered. Therefore, Eq. (2) is an operator extension of weak monotonicity. In fact, this inequality can be extended to an inequality involving two independent density matrices $\rho$ and $\sigma$. Let $\rho_{AB}$ and $\sigma_{BC}$ be positive definite density matrices acting on $\mathcal{H}_A \otimes \mathcal{H}_B$ and $\mathcal{H}_B \otimes \mathcal{H}_C$, respectively. We show that

$$\log \rho_{AB} - \log \rho_A + \log \sigma_{BC} - \log \sigma_C \leq 0,$$ (3)

again suppressing the tensor product with the identity operator.

These inequalities are somewhat surprising because $\log \rho_{AB} - \log \rho_A$ can have positive eigenvalues in general. In particular, in Eq. (3), we emphasize again that $\rho$ and $\sigma$ need not be related to each other in any way. While $\log \rho_{AB} - \log \rho_A$ and $\log \sigma_{BC} - \log \sigma_C$ may have positive eigenvalues, their sum, after accounting for the tensor product with the identity, apparently cannot.
The proofs of these inequalities are based on a certain operator inequality involving marginal density matrices and the fact that \( f(t) = \ln t \) is an operator monotone function \([2, 3]\). We remark that this operator inequality has some resemblance to an inequality known in the algebraic quantum field theory literature \([4, 5]\). However, as we discuss later in Section 3, there are important differences between the two.

Let us make some historical remarks. Since Lieb and Ruskai’s seminal proof of strong subadditivity \([1]\), several strengthenings have appeared in the literature. Carlen and Lieb proved a strengthening which can become nontrivial for entangled quantum states \([6]\). One of us proved an operator extension \([7, 8]\). A strengthening that ensures a robust form of recoverability was proved in Ref. [9, 10, 11]. Our operator extension of weak monotonicity can be viewed as yet another strengthening of strong subadditivity. In particular, we reprove, using this new inequality, the operator extension of strong subadditivity \([7]\); see Corollary 1. Thus our new inequality is at least as strong as the operator extension of strong subadditivity.

Another perspective is that we provide an arguably simplest approach to prove strong subadditivity of entropy. Our key observation is that a nontrivial inequality can be obtained by combining Stinespring dilations \([12]\) of Petz’s transpose maps \([13]\). The proof of this inequality is elementary, and once this inequality is obtained, the weak monotonicity follows from an elementary application of Löwner-Heinz’s theorem \([2, 3]\) on matrix monotone functions. The strong subadditivity then follows by introducing a purifying system, a fact that is well-known in the literature. This observation suggests a possibility of deriving new matrix inequalities from dilations of channels.

The rest of the paper is organized as follows. The proofs of our claims (and their generalizations) are presented in Section 2. In Section 3, we comment on a relation between our inequalities and a similar inequality in quantum field theory. We end with a discussion in Section 4.

2 Proofs

Let us begin by first setting up the notation. Let \( \mathcal{H} \) be a finite-dimensional Hilbert space. We denote the set of density matrices on \( \mathcal{H} \) as \( S(\mathcal{H}) \). The set of density matrices which are strictly positive is denoted as \( S(\mathcal{H})_{++} \). For simplicity, throughout the paper, we focus on the cases where the density matrices are strictly positive definite. We expect a generalization of our results for positive semi-definite density matrices would require a projection onto an appropriate subspace, which we leave for future work.

Given a density matrix, we shall denote its marginals by specifying the subsystem in the subscript. For example, \( \rho_A \) is a marginal of a density matrix \( \rho \) on \( \mathcal{H}_A \). We shall denote the operator norm of \( M \) as \( \|M\| \) and the identity acting on \( \mathcal{H}_X \) as \( I_X \).

Here is the key lemma.

**Lemma 1.** For any \( \rho_{AB} \in S(\mathcal{H}_A \otimes \mathcal{H}_B)_{++} \) and \( \sigma_{BC} \in S(\mathcal{H}_B \otimes \mathcal{H}_C)_{++} \),

\[
\rho_A^{-1} \otimes \sigma_{BC} \leq \rho_{AB}^{-1} \otimes \sigma_{BC}.
\]

**Proof.** Let \( \rho_{AB} \in S(\mathcal{H}_A \otimes \mathcal{H}_B)_{++} \). Consider an operator \( V_{A \rightarrow ABB^*}^\rho : \mathcal{H}_A \rightarrow \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_{B^*} \) defined as follows:

\[
V_{A \rightarrow ABB^*}^\rho := \frac{1}{2} \rho_{AB}^{-\frac{1}{2}} \sum_k |k\rangle_B \langle k|_{B^*},
\]

where \( \mathcal{H}_{B^*} \) is an auxiliary Hilbert space such that \( \dim(\mathcal{H}_{B^*}) = \dim(\mathcal{H}_B) \), and the summation is taken over a set of orthonormal basis for \( \mathcal{H}_{B^*} \) and \( \mathcal{H}_B \). A straightforward calculation shows that \( V_{A \rightarrow ABB^*}^\rho V_{A \rightarrow ABB^*}^{\rho^*} = I_A \). Thus, \( V_{A \rightarrow ABB^*}^\rho \) is an isometry. Similarly, we can define

\[
V_{C \rightarrow BB^*C}^\sigma := \frac{1}{2} \sigma_{BC}^{-\frac{1}{2}} \sum_k |k\rangle_B \langle k|_{B^*},
\]

which is also an isometry.

Let \( V_{B \rightarrow B^*} : \mathcal{H}_B \rightarrow \mathcal{H}_{B^*} \) be an isometry, where \( \mathcal{H}_{B^*} \) is an auxiliary Hilbert space we use in the following argument. Define \( V_{A \rightarrow AB'B^*}^\rho : \mathcal{H}_A \rightarrow \mathcal{H}_A \otimes \mathcal{H}_{B'} \otimes \mathcal{H}_{B^*} \) as follows:

\[
V_{A \rightarrow AB'B^*}^\rho := V_{B \rightarrow B^*} V_{A \rightarrow ABB^*}^\rho.
\]
Consider the operator $V_{B\rightarrow B'}^\dagger V_{C\rightarrow BB'C}^\sigma V_{A\rightarrow A'B'B^*}^\rho : \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C \rightarrow \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C$. Since the operator norm of an isometry is 1, we conclude
\[
\|V_{B\rightarrow B'}^\dagger V_{C\rightarrow BB'C}^\sigma V_{A\rightarrow A'B'B^*}^\rho\| \leq 1. \quad (8)
\]
A straightforward calculation shows that
\[
V_{B\rightarrow B'}^\dagger V_{C\rightarrow BB'C}^\sigma V_{A\rightarrow A'B'B^*}^\rho = \sum_{k,k',k'',k'''} |k''')_B\langle k''|B\langle k'|B\sigma_C^{-\frac{1}{2}}B\sigma_{BC}^{-\frac{1}{2}}|k'|B\rho_{AB}\rho_A^{-\frac{1}{2}}|k\rangle B
\]
\[
= \sum_{k,k'} |k'\rangle_B\langle k''|B\sigma_C^{-\frac{1}{2}}B\sigma_{BC}^{-\frac{1}{2}}\rho_{AB}\rho_A^{-\frac{1}{2}}|k\rangle B
\]
\[
= \left(\rho_{AB}^{-\frac{1}{2}} \otimes \sigma_C^{-\frac{1}{2}}\right)\left(\rho_A^{-\frac{1}{2}} \otimes \sigma_{BC}^{-\frac{1}{2}}\right).
\]
We therefore obtain
\[
\left\|\left(\rho_{AB}^{-\frac{1}{2}} \otimes \sigma_C^{-\frac{1}{2}}\right)\left(\rho_A^{-\frac{1}{2}} \otimes \sigma_{BC}^{-\frac{1}{2}}\right)\right\| \leq 1
\]
leading to
\[
\left(\rho_{AB}^{-\frac{1}{2}} \otimes \sigma_C^{-\frac{1}{2}}\right)\left(\rho_A^{-\frac{1}{2}} \otimes \sigma_{BC}^{-\frac{1}{2}}\right) \leq I_{ABC},
\]
from which the main claim immediately follows. □

A crucial step of the proof is Eq. (9), and here we provide a diagrammatic version of this argument, in order to provide an intuition to the readers. We shall first denote $V_{A\rightarrow ABB^*}^\rho$ and $V_{C\rightarrow BB'C}^\sigma$ as follows:

\[
V_{A\rightarrow ABB^*}^\rho = \begin{array}{c}
A \\
\rho_{AB}^{-\frac{1}{2}}
\end{array} \rightarrow \begin{array}{c}
B \\
\frac{1}{2}
\end{array} \rightarrow \begin{array}{c}
C \\
\sigma_{BC}^{-\frac{1}{2}}
\end{array}, \quad V_{C\rightarrow BB'C}^\sigma = \begin{array}{c}
B \\
\sigma_C^{-\frac{1}{2}}
\end{array} \rightarrow \begin{array}{c}
C \\
\frac{1}{2}
\end{array} \rightarrow \begin{array}{c}
B^* \\
\sigma_{BC}^{-\frac{1}{2}}
\end{array}.
\]

(12)

In these diagrams, the input and the output of the maps lie on the left and the right side of the diagram, respectively. Each leg is labeled by the respective subsystem, and the curved leg connecting $B$ and $B^*$ represents $\sum_k |k\rangle_B\langle k|_{B'}$. We can similarly represent $V_{A\rightarrow A'B'B^*}^\rho$ as follows:

\[
V_{A\rightarrow A'B'B^*}^\rho = \begin{array}{c}
A \\
\rho_{AB}^{-\frac{1}{2}}
\end{array} \rightarrow \begin{array}{c}
B \\
\frac{1}{2}
\end{array} \rightarrow \begin{array}{c}
B' \\
\sigma_{BC}^{-\frac{1}{2}}
\end{array} \rightarrow \begin{array}{c}
B^* \\
\frac{1}{2}
\end{array},
\]

(13)

where the triangle corresponds to $V_{B\rightarrow B'}$ and the curved leg connecting $B$ and $B^*$ is now $\sum_k |k\rangle_B\langle k|_{B'}$. We
can thus obtain

\[
V_{C \rightarrow BB'C}^\rho V_{A \rightarrow ABB'}^\rho = \begin{pmatrix}
\frac{1}{\sqrt{2}} \rho_{AB} & 0 \\
0 & \frac{1}{\sqrt{2}} \sigma_{BC}
\end{pmatrix}
\begin{pmatrix}
B^* \\
B'
\end{pmatrix}
\]

where the second line is obtained by simply “straightening out” the curved leg. At this point, it is straightforward to see that

\[
\begin{pmatrix}
\frac{1}{\sqrt{2}} \rho_{AB} & 0 \\
0 & \frac{1}{\sqrt{2}} \sigma_{BC}
\end{pmatrix}
\begin{pmatrix}
B^* \\
B'
\end{pmatrix} = \begin{pmatrix}
A \\
A
\end{pmatrix} \quad (14)
\]

Remark 1. The isometry \(V_{A \rightarrow ABB'}^\rho\) is the Stinespring dilation [12] of Petz’s transpose map [13].

By the L"owner-Heinz theorem [2, 3], \(f(t) = \log t\) is operator monotone. Thus, we immediately obtain the following result.

**Theorem 2.** For any \(\rho_{AB} \in S(H_A \otimes H_B)_{++}\) and \(\sigma_{BC} \in S(H_B \otimes H_C)_{++}\),

\[
\log \rho_{AB} - \log \rho_A + \log \sigma_{BC} - \log \sigma_C \leq 0. \quad (15)
\]

We remark that, by taking \(\rho_{AB}\) and \(\sigma_{BC}\) as the marginal density matrices of \(\rho_{ABC}\), Eq. (2) follows. Moreover, by taking an expectation value with respect to \(\rho_{ABC}\), weak monotonicity, and subsequently, the strong subadditivity of entropy [1] follows as well.

Moreover, Theorem 2 implies the operator extension of strong subadditivity [7, 8].

**Corollary 1.** For any \(\rho_{ABC} \in S(H_A \otimes H_B \otimes H_C)_{++}\),

\[
\text{Tr}_{BC}(\rho_{ABC}(\log \rho_{ABC} + \log \rho_B - \log \rho_{AB} - \log \rho_{BC})) \geq 0. \quad (16)
\]

*Proof.* Consider a purification of \(\rho_{ABC}\), denoted as \(|\rho\rangle_{ABCD}\), where \(D\) is the purifying space. By Theorem 2,

\[
\log \rho_{BC} - \log \rho_B + \log \rho_{CD} - \log \rho_D \leq 0. \quad (17)
\]

For any \(M_A\) acting on \(H_A\),

\[
\langle \rho | (M_A^\dagger \otimes I_{BCD})(\log \rho_{BC} + \log \rho_{CD} - \log \rho_B - \log \rho_D)(M_A \otimes I_{BCD})|\rho \rangle \leq 0. \quad (18)
\]

Since \(\log \rho_{CD} |\rho \rangle = \log \rho_{AB} |\rho \rangle\) and \(\log \rho_D |\rho \rangle = \log \rho_{ABC} |\rho \rangle\), we get

\[
\text{Tr}_A \left( M_A^\dagger M_A \text{Tr}_{BC}(\rho_{ABC}(\log \rho_{ABC} + \log \rho_B - \log \rho_{AB} - \log \rho_{BC})) \right) \geq 0, \quad (19)
\]

which implies the claim. \(\Box\)
The Löwner-Heinz theorem also implies that \( f(t) = t^\alpha \) is operator monotone for \( \alpha \in [0,1] \). Thus, the following theorem also follows, which can be viewed as a Rényi generalization of Theorem 2.

**Theorem 3.** For any \( \rho_{AB} \in S (\mathcal{H}_A \otimes \mathcal{H}_B)_{++} \) and \( \sigma_{BC} \in S (\mathcal{H}_B \otimes \mathcal{H}_C)_{++} \),

\[
\rho_A^{-\alpha} \otimes \sigma_{BC}^\alpha \leq \rho_{AB}^{-\alpha} \otimes \sigma_{BC}^\alpha, \tag{20}
\]

for \( \alpha \in [0,1] \).

### 3 A related inequality from algebraic quantum field theory

We remark that there is a known result in the algebraic quantum field theory literature [5] which appears similar to Lemma 1. Here we introduce this result and comment on this similarity. (An introduction to von Neumann algebra and related concepts can be found in Ref. [5].) Let \( \mathcal{H} \) be a Hilbert space. Let \( |\Psi\rangle \in \mathcal{H} \) be a cyclic and separating vector for a von Neumann algebra \( \mathcal{A} \) on \( \mathcal{H} \). Let \( |\Psi\rangle, |\Phi\rangle \in \mathcal{H} \) be vectors for a von Neumann algebra \( \mathcal{A} \) on \( \mathcal{H} \) where \( |\Psi\rangle \) is cyclic and separating over \( \mathcal{A} \). Then we can define a relative modular operator [14] as \( \Delta_{\Psi|\Phi;A} = S_{\Psi|\Phi;A} S_{\Psi|\Phi;A}^\dagger \) where \( S_{\Psi|\Phi} \) is an anti-linear operator such that for any \( a \in \mathcal{A} \),

\[
S_{\Psi|\Phi;A} a |\Psi\rangle = a^\dagger |\Phi\rangle. \tag{21}
\]

Let \( \mathcal{A}_1 \) be an algebra. It is known that, for any algebra \( \mathcal{A}_2 \subset \mathcal{A}_1 \), the following inequality holds:

\[
\Delta_{\Psi|\Phi;A_2} \geq \Delta_{\Psi|\Phi;A_1}, \tag{22}
\]

which can be found in [4, Equation (2.1.3)], and more recently, [5, Equation (3.36)]. This inequality makes sense only if both sides are well-defined, which requires \( \Psi \) to be cyclic and separating for both \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \).

To show the similarity and the difference between Eq. (22) and Lemma 1, let us consider the following plausible but incorrect argument to prove Theorem 2. Let \( |\Psi\rangle, |\Phi\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C \otimes \mathcal{H}_D \), where \( \mathcal{H}_A, \mathcal{H}_B, \mathcal{H}_C, \) and \( \mathcal{H}_D \) are finite-dimensional Hilbert spaces. Let \( |\Psi\rangle \) be a purification of \( \rho_{AB} \) and \( |\Phi\rangle \) be a purification of \( \sigma_{BC} \), both assumed to be of full rank. Define the following algebras:

\[
\mathcal{A}_1 = \{ I_A \otimes M_{BCD} : M_{BCD} \in \mathcal{B}(\mathcal{H}_B \otimes \mathcal{H}_C \otimes \mathcal{H}_D) \},
\]

\[
\mathcal{A}_2 = \{ I_{AB} \otimes M_{CD} : M_{CD} \in \mathcal{B}(\mathcal{H}_C \otimes \mathcal{H}_D) \}, \tag{23}
\]

where \( \mathcal{B}(\mathcal{H}) \) is the space of bounded operators acting on \( \mathcal{H} \).

If we can find \( |\Psi\rangle \) which is cyclic and separating for both \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \), following [5, Sec. 4], the relative modular operators become

\[
\Delta_{\Psi|\Phi;A_2} = \rho_{AB}^{-1} \otimes \sigma_{CD}, \quad \Delta_{\Psi|\Phi;A_1} = \rho_A^{-1} \otimes \sigma_{BC}. \tag{24}
\]

If Eq. (24) is correct, we could use Eq. (22) and take a partial trace on \( D \) over both sides, obtaining

\[
\rho_{AB}^{-1} \otimes \sigma_C \geq \rho_A^{-1} \otimes \sigma_{BC}, \tag{25}
\]

which is exactly Lemma 1.

Unfortunately, such \( |\Psi\rangle \) does not exist in general when the Hilbert spaces are finite-dimensional. This is because \( \dim \mathcal{H}_A = \dim (\mathcal{H}_B \otimes \mathcal{H}_C \otimes \mathcal{H}_D) \) when \( |\Psi\rangle \) is cyclic and separating for \( \mathcal{A}_1 \) and \( \dim (\mathcal{H}_A \otimes \mathcal{H}_B) = \dim (\mathcal{H}_C \otimes \mathcal{H}_D) \) when \( |\Psi\rangle \) is cyclic and separating for \( \mathcal{A}_2 \). The two conditions cannot simultaneously hold in general for finite-dimensional Hilbert spaces unless \( \dim \mathcal{H}_B = 1 \). Interestingly, this issue does not arise in certain states of quantum field theory. For instance, any vacuum state is both cyclic and separating for any field algebra associated to an open set of the Minkowski space, thanks to the Reeh-Schlieder theorem [5, 15]. One may hope to circumvent this issue of cyclic and separating condition by considering a more general definition of relative modular operators that does not require the state to be cyclic or separating [16, Appendix A]. However, it is then not obvious if Eq. (22) is true because under such definition, it is not clear if \( S_{\Psi|\Phi;A_1} \) is an extension of \( S_{\Psi|\Phi;A_2} \).
4 Discussion

In this paper, we proved an operator extension of weak monotonicity. It is interesting to note that our argument also leads to yet another proof of strong subadditivity \[1\]. What is notable about this new proof is that the strong subadditivity is proved by first proving the weak monotonicity, not the other way around. The key observation was Lemma \[1\], which followed immediately from constructions of certain isometries. We leave it as an open problem to explore the consequences of this simple but powerful observation.
