Effects of corticosterone on the metabolic activity of cultured chicken chondrocytes

Hua Zhang, Zhenlei Zhou*, Jingwen Luo and Jiafa Hou

Abstract

Background: Corticosterone is one of the most crucial glucocorticoids (GCs) in poultry. Our previous study shows that corticosterone can retard the longitudinal growth of bones by depressing the proliferation and differentiation of chondrocytes in broilers. The present study was designed to investigate whether corticosterone affect the development of chondrocytes and the synthesis of collagen in vitro. The chondrocytes were isolated from proximal tibial growth plates of 6-week-old broiler chickens and cultured with different doses of corticosterone for 48 h. Then the cell viability, alkaline phosphatase (ALP) activity and the expression of parathyroid hormone-related peptide (PTHrP) and type X collagen (Col X) were detected.

Results: At $10^{-9}$-$10^{-6}$ M concentration, corticosterone significantly inhibited the viability and differentiation of chondrocytes, as indicated by decreases in ALP and type X collagen expression. Conversely, there was completely opposite effect at $10^{-10}$ M. In addition, the expression of PTHrP was significantly downregulated at $10^{-6}$ M and $10^{-8}$ M, and was upregulated at $10^{-10}$ M.

Conclusions: The results suggested that corticosterone regulated chicken chondrocytes performance depending on its concentration with high concentrations inhibiting the viability and differentiation of chondrocytes and light concentrations promoting them, and these roles of corticosterone may be in part mediated through PTHrP.

Keywords: Corticosterone, Chondrocytes, ALP, Col X, PTHrP

Background

Longitudinal bone growth depends on the proliferation, differentiation of growth plate chondrocytes by complex endocrine regulation [1]. It is well known that glucocorticoids (GCs) have complex effects on bone metabolism. Prolonged or high dose glucocorticoid administration as well as an excess of endogenous production of GCs increases the risk of bone disorders [2]. Corticosterone (CORT) is the main glucocorticoid hormone in birds [3] and in charge of bone metabolism [2]. Numerous studies had been conducted concerning the effects of GCs on growth retardation in mammals [4-15] and were to some extent controversial [16,17], whereas relatively few data were available with regard to its roles in bone development in avian.

It was reported that parathyroid hormone-related peptide (PTHrP) was one of the important cytokines. Both the periarticular perichondrium and growth plate chondrocytes are the source of PTHrP [18,19]. Ablation of the PTHrP gene exhibits a delay in chondrocyte differentiation and leads to distinct abnormalities in bone development [20]. PTHrP directly stimulates chondrocyte proliferation and prevents the differentiation of proliferating chondrocytes to prehypertrophic cells [21,22]. Type X collagen (Col X) expressing exclusively in the matrix of the hypertrophic zone [23,24] is one of the well-known markers of chondrocyte hypertrophy [25,26].

Previous studies from our laboratory showed that exposure to CORT depressed the longitudinal growth of the long bones by inhibiting the proliferation and differentiation of chondrocytes in growth plate in broilers [27], but the effects of CORT on the cellular events that occurred during this process in birds were uncertain, the present study was designed to investigate whether CORT affect the performance of chondrocytes obtained from the epiphyseal growth plates of broiler chickens by determining the ALP activity and expression of PTHrP and ColX.
Results

Effect of CORT on cell viability and ALP activity in cultured chicken chondrocytes

The results showed that CORT inhibited chondrocytes viability and ALP activity significantly at concentrations of $10^{-9}$ M to $10^{-6}$ M in a dose-dependent manner (Figures 1 and 2). The lowest chondrocytes viability was observed at $10^{-6}$ M CORT reducing the cell viability as great as to 64.2% of the control. And the lowest ALP activity (150.57 ± 10.591 nmol/min/mg) was also measured at $10^{-6}$ M CORT. However, $10^{-10}$ M CORT administration did not affect chondrocytes viability and ALP activity. Additional tables file show this in more detail [see Additional files 1 and 2]. Based on these results, $10^{-10}$ M, $10^{-8}$ M and $10^{-6}$ M CORT (as low, middle and high concentration, respectively) were determined to evaluate its roles in the regulation of gene expression in cultured growth plate chondrocytes.

Effect of CORT on expression of PTHrP and ColX in cultured chicken chondrocytes

Expression of related genes was investigated after 48 h exposure of different doses of CORT ($10^{-10}$ M, $10^{-9}$ M and $10^{-6}$ M). Real-time RT-PCR showed that $10^{-10}$ M CORT resulted in obviously increasing the expression of PTHrP and Col X (Figure 3A and B). Furthermore, $10^{-8}$ M and $10^{-6}$ M CORT significantly declined PTHrP and Col X mRNA levels, and the inhibition exerted at the concentration of $10^{-6}$ M CORT was more effective. The Col X protein levels (expressed as the Col X: Gapdh ratio) displayed the same changes as its mRNA expression after CORT treatment (Figure 4).

Discussion

In the present study, we investigated the effects of CORT on cultured chicken growth plate chondrocytes in terms of cell viability, ALP activity and the expression of Col X and PTHrP. Growth plate chondrocytes were exquisitely sensitive to GCs [6,27,28]. The results showed that PTHrP signaling could play a crucial role in regulating the viability and differentiation of growth plate chondrocytes of chickens.

Based on the present study, MTT assay was performed to evaluate the effect of CORT on the viability of chondrocytes for 48 h. Interestingly, CORT at the concentration of $10^{-10}$-$10^{-6}$ M didn’t have a clear dose-dependent effect on cell viability. CORT could inhibit chondrocytes viability at the concentration of $10^{-9}$-$10^{-6}$ M and have no effect with $10^{-10}$ M. R. Quarto et al. [17] suggested that GCs can support chondrocytes viability. However, it was difficult to compare our observations with other studies because the origin of the investigated chondrocytes, the culture conditions, the types and doses of GCs and the exposure times were distinct.

The process of endochondral ossification which consists of cartilage formation and replacement of cartilage by bone plays a major role in bone development [29]. The chondrocytes actively proliferate and synthesize a large amount of extracellular matrix components undergo a series of maturation events. They advance to

**Figure 1** Effects of various doses CORT on cell viability measured by MTT assay. The cells were incubated with increasing concentrations of CORT for 48 h. Treated cell viabilities were expressed as a percentage of control (100%). Data were mean ± SEM from at least three separate experiments, each performed in triplicates. *P < 0.05 and **P < 0.01 versus control (0 M CORT).
the hypertrophic stage, which is characterized by the expression of type X collagen and ALP [30]. In the process of chondrocytes maturation, ALP secreted from chondrocytes could convert organic phosphorus esters to inorganic phosphates by hydrolysis, forming a hydroxyapatite precursor which then undergoes calcification [31]. Therefore, ALP is recommended as a marker of chondrocyte maturation [32]. In this study, we observed that the decrease in ALP activity was accompanied by a decline in the viability of chondrocytes after CORT treatment at $10^{-9} - 10^{-6}$ M. It indicated that the suppression of chondrocyte differentiation and the reduction of ALP activity may be due to inhibitory effect of CORT on the viability of chondrocytes.

Col X, which is a recognized marker of chondrocyte hypertrophy, is mainly synthesized by hypertrophic chondrocytes and plays a key role in endochondral ossification. The current study showed that the expression

Figure 3 Effects of CORT on PTHrP and Col X mRNAs expression in cultured Chondrocytes (A-B). The cells were incubated with various doses of CORT for 48 h. The relative expression of PTHrP and Col X genes was analysed by real-time PCR. Gene expression was normalized using GAPDH as an internal control. Values were mean ± SEM from at least three separate experiments, each performed in triplicates. *$P < 0.05$ and **$P < 0.01$ versus control (0 M CORT).
of Col X was inhibited by CORT with middle and high concentration, while the expression of Col X was significantly increased with low concentration CORT treatment. These results provided an evidence for our previous study in vivo that excess CORT inhibited the growth of proliferative and prehypertrophic chondrocytes and the synthesis of Col X [27]. This finding, together with the variation of ALP activity and cell viability, clearly indicated that CORT not only affected cell viability, but also inhibited the differentiation process of growth plate chondrocytes.

A number of growth factors are known to be regulators of chondrocytes development. PTHrP plays important roles in longitudinal bone growth, as it is a negative regulator of growth plate chondrocytes terminal differentiation [18]. As a key cytokine, PTHrP maintains chondrocytes in a proliferative state and regulate chondrocytes proliferation [33,34]. PTHrP blocks matrix calcification and decrease ALP activity markedly in chondrocytes through PKC/p38 signaling pathways [30]. The present study showed that CORT had distinct impact on the expression of PTHrP mRNA with various concentrations. In addition, the changes of levels of Col X and ALP in chondrocytes were coordinated with trends of PTHrP expression following treatment with CORT. Our finding indicated that the regulation of the viability and differentiation of chondrocytes by CORT might be in part mediated through by PTHrP. More studies were still needed to further to determine whether there were interactions between CORT and PTHrP.

Conclusions
Based on the outcome, our data confirmed that CORT had profound impacts upon bone growth through orderly process of differentiation of growth plate chondrocytes reported by our previous study but now amongst in vivo circumstances [27]. PTHrP may play a certain role in regulating chondrocytes growth induced by CORT. The effect of CORT may be in part mediated by the expression of PTHrP.

Methods
Chemicals and reagents
Dulbecco's modified eagle's medium (DMEM), penicillin-streptomycin solution, fetal bovine serum (FBS), amphotericin B solution, collagen type IV and Trizol reagent were procured from Invitrogen, Carlsbad, CA, USA. Bovine testicular hyaluronidase, a nonessential amino acids mixture (100×) and CORT were purchased from Sigma-Aldrich, Shanghai, China. Two-step reverse-transcriptase polymerase chain reaction kit was purchased from TaKaRa Biotechnology (Dalian) Co., Ltd., China. Col X antibody, anti Gapdh mouse monoclonal antibody, HRP conjugated goat anti-rabbit IgG (H+L) and HRP conjugated goat antimouse IgG (H+L) were purchased from Otwo Biotech Co., Ltd., China. Cell lysis buffer for Western was procured from Beyotime Institute of Biotechnology, China. Other chemicals and reagents used in the present study were of analytical grade and were obtained from the Jiancheng Biotechnology Institute (Nanjing, China) unless otherwise indicated.
All animal work was performed according to the international animal welfare guidelines, and protocols were approved by Nanjing Agricultural University Animal Care Committee. Animal studies were conducted in accordance with the recommendations in the Guidelines for the Care and Use of Laboratory Animals of the Ministry of Science and Technology of the People’s Republic of China ([2006] 398).

**Cell culture and treatment**

Growth plate cartilage was harvested from the proximal end of the tibia of 6-week-old hybrid broiler chickens and chondrocytes were isolated as previously described [35]. Briefly, tibial growth plate slices were treated in a digest solution (0.1% type IV collagenase, 0.1% hyaluronidase, 5% FBS) and incubated at 37°C overnight. The resulting crude cell preparations were further purified on lymphocyte separation medium (MP Biomedicals, LLC, California, USA), resuspended and counting, then inoculated to multi-well plates containing complete medium with the density for10^6 cell/cm^2. Culture medium (10% FBS, 1% nonessential amino acids mixture) was changed every other day with a fresh supplement of ascorbic acid (50 μg/ml) from day 3 onward, for the duration of the experiments. To facilitate cell attachment, 4U/ml testicular hyaluronidase was added to the medium. After the attachment of cells, the growth medium was then removed and cells were exposed to different doses of CORT (10^{-10} - 10^{-6} M) using serum-free fresh medium at 37°C and 5% CO_2 for 48 h. All culture media contained 100 IU/ml of penicillin, 100 μg/ml of streptomycin and 0.25 μg/ml of amphotericin B.

**MTT assay**

Cell viability was assessed by the ability of mitochondrial dehydrogenases to oxidize the 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) to a purple formazan product [27]. After 48 h exposure, 20 μl MTT (5 mg/ml) was added into each well and incubated for 4 h at 37°C. Purple formazan crystals were solubilized in dimethyl sulfoxide for 10 min at 37°C. The absorbance at 570 nm was measured in a Bio-Rad microplate reader (Bio-Rad Laboratories, Hercules, CA). A Light Cycler melting curve was constructed to test for a single product at the end of each PCR reaction. Analysis of the relative gene expression level was achieved by using the 2^-ΔΔCt method for fold induction, and C_T (the threshold cycle) indicated the fractional cycle number at which the amount of amplified target reached a fixed threshold [37].

**Western blot analysis**

After 48 h exposure of CORT (10^{-10} M, 10^{-8} M and 10^{-6} M), chondrocyte lysates were prepared with RIPA

**Alkaline phosphatase (ALP) activity**

Cell layers were washed twice with cold phosphate buffered saline (PBS pH = 7.4). The cell suspension was homogenized and 50 μl of each sample was aliquoted into a 96-well plate in duplicate to assay ALP activity and protein content [36]. 150 μl of a buffer solution consisting of 10 mM p-nitrophenyl phosphate (pNPP), 0.2 mM MgCl_2 and 1 mM diethanolamine was added to each sample [35]. After incubated at 37°C for 30 min and then 100 μl of 0.1 M NaOH was added to stop the reaction. The plates were read in a Bio-Rad microplate reader at 405 nm. The ALP activity was determined by comparing the experimental samples with standard solutions of p-nitrophenol and an appropriate blank. Protein concentrations of the samples were determined using the BCA assay kit (Wuhan Boster Company, Wuhan, China). Each sample was normalized by the total protein content per well to determine specific activity. Total ALP activity was expressed as nmoles pNPP hydrolysed/min/mg protein.

**Real-time RT-PCR**

Total RNA was isolated from chondrocytes using Trizol reagent after 48 h exposure of different doses of CORT (10^{-10} M, 10^{-8} M and 10^{-6} M). Real-time RT-PCR was carried out using two-step RT-PCR kit per the instructions of the manufacturer. Gapdh, the house-keeping gene, was used as an internal control of the quantity and quality of the cDNAs. The primer sequences used for PCR amplification for Col X, PTHrP and Gapdh were listed in Table 1. Real-time PCR amplification was performed on LightCycler (Applied Biosystems, Inc., Foster City, CA). A Light Cycler melting curve was constructed to test for a single product at the end of each PCR reaction. Analysis of the relative gene expression level was achieved by using the 2^-ΔΔCt method for fold induction, and C_T (the threshold cycle) indicated the fractional cycle number at which the amount of amplified target reached a fixed threshold [37].

|          | Anti-sense: CGGCAAGGTCAAGTCAACA               |                  |                      |

*The primers of Col X was quoted from Reference [38].
Lysis buffer (Beyotime, Nanjing, China), and centrifuged at 12,000 g. Protein concentration was determined by using the BCA assay kit. Fifty micrograms of total protein (per lane) were resolved by sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE; 10% acrylamide) and transferred onto a nitrocellulose membrane. The membranes were blocked with 5% skimmed milk in Tris-buffered saline-Tween (TBS-T) for 2 hours and then probed with antibodies. The primary antibodies to Col X (diluted 1:200), and anti-Gapdh (diluted 1:5000) were used. HRP conjugated goat anti-rabbit or mouse IgG (H+L) (diluted 1:5000) was used as a secondary antibody. Visualization of immunoreactive proteins was achieved using the ECL Western blotting detection reagents (Millipore Corporation, Billerica, USA). Molecular weights of the immunoreactive proteins were determined against a protein marker ladder. Band density was quantitated using the Quantity One software (Bio-Rad Laboratories, Hercules, CA).

Statistical analysis
Tests were carried out in triplicate and all experiments were performed a minimum of three times, and the mean and standard error of the mean (SEM) were determined. Statistical analyses were conducted using SPSS 11.0 for Windows (SPSS Inc., Chicago, IL, USA). Data were analyzed by one-way Analysis of variance (ANOVA) followed by Duncan’s multiple range tests to assess the significance between the control and experimental groups. Statistical significance was considered at the level of P < 0.05.
