Abstract
We give a review of our recent works related to the Malliavin Calculus of Bismut type for non markovian generator. Part IV is new and relates the Malliavin Calculus and the general theory of elliptic pseudo-differential operators.

1 Introduction
Le $M$ be a compact Riemannian manifold endowed with its natural Riemannian measure $dx$ ($x$ is the generic element of $M$). In local coordinates, we can think of the linear space $\mathbb{R}^d$ endowed with the metric $g_{i,j}(x)dx^i \otimes dx^j$ where $x \rightarrow (g_{..}(x))$ is a smooth function from $\mathbb{R}^d$ into the space of symmetric strictly positive matix. The Riemannian measure associated is

$$dx = \det(g_{..})^{-1/2}dx^1.. \otimes dx^d$$ (1)

We consider a linear symmetric positive operator densely defined on $L^2(dx)$ acting on a space which separates the point on $M$. This means if $f$ and $g$ belong to this space,

$$\int_M g(x)Lh(x)dx = \int_M h(x)Lg(x)dx$$ (2)

$$\int_M h(x)Lh(x)dx \geq 0$$ (3)

It has by abstract theory a selfadjoint extension on $L^2(dx)$, which generates a contraction semi-group $P_t$ on $L^2(dx)$ which solves the heat equation for $t > 0$

$$\frac{\partial}{\partial t} P_t h = -LP_t h$$ (4)
with initial condition
\[ P_0h = h \] (5)

It is a natural question to know if there is a heat kernel:
\[ P_t h(x) = \int_M p_t(x, y) h(y) dy \] (6)

There are several ways to solve this problem:

- The microlocal analysis ([12], [18], [19]) which uses as basic tool the Fourier transform and some regularity on the coefficients of \( L \). In the case of a partial differential operator on \( \mathbb{R}^d \), this means that \( L = \sum a_{(\alpha)}(x) \frac{\partial^{(\alpha)}}{\partial x} \) where \( (\alpha) \) is a multiindex and \( x \to a_{(\alpha)}(x) \) is smooth.

- The harmonic analysis, which uses as basic tools functional inequalities and does not need any regularity on the coefficients of \( L \) ([3], [13], [51]).

- The Malliavin Calculus([20], [44], [49]), which works for Markov semi-groups: \( P_t f \geq 0 \) if \( f \geq 0 \). The Malliavin Calculus requires moreover that the semi-group is represented by a stochastic differential equation.

More precisely, the Malliavin Calculus needs a probabilistic representation of the semi-group \( P_t \) by using the theory of stochastic differential equations where a flat Brownian motion or a Poisson process play a fundamental role.

Let us recall the main idea of the Malliavin Calculus in the case of the flat Brownian motion. Let us consider the Hilbert space \( \mathbb{H} \) of finite energy maps starting from 0 from \([0,1]\) into \( \mathbb{R}^m \) endowed with the Hilbert norm

\[ \|r\|^2 = \sum_{i=1}^{m} \int_0^1 |d/dtr^i|^2 dt \] (7)

We consider the formal Gaussian measure on \( \mathbb{H} \) (written in the heuristic way of Feynman path integral)\n
\[ d\mu(r) = 1/Z \exp \left[ -\|r\|^2/2 \right] dD(r) \] (8)

where \( dD(r) \) is the formal Lebesgue measure on \( \mathbb{H} \). Haar measure satisfying all the axioms of measure theory on a group exists if and only the group is locally compact. (We refer to [2] and [30] to defined Haar measure in infinite dimension in a generalized way). This explains that we need to construct this measure on a bigger space, the space of continuous function \( C([0,1], \mathbb{R}^m) t \rightarrow B_t \) issued from 0 from \([0,1]\) into \( \mathbb{R}^m \). There are a lot of Gaussian measures on \( C([0,1], \mathbb{R}^m) \) ([48]) but the law of the Brownian motion is related to the heat equation on \( \mathbb{R}^m \)

\[ \frac{\partial}{\partial t} P_t f(x) = 1/2 \sum_{i=1}^{m} \frac{\partial^2}{\partial x^i} P_t f(x) \] (9)

We have namely
\[ P_t h(x) = E[h(B_t + x)] \] (10)

if \( f \) is a bounded continuous function on \( \mathbb{R}^m \). In such a case we have a semigroup operating on continuous function on \( \mathbb{R}^m \).
We consider $m$ smooth vector fields on $\mathbb{R}^d$ with bounded derivatives at each order. Vector fields here are considered as first order partial differential operators. We consider the operator

$$L = \frac{1}{2} \sum_{i=1}^{m} X_i^2$$

We introduce the Stratonovitch differential equation ([20], [49]) starting from $x$ (Vector fields here are considered as vectors which depends smoothly of $x$):

$$dx_t(x) = \sum_{i=1}^{m} X_i(x_t(x)) dB_i^t$$

This is (and not the Ito equation) the correct equation associated to

$$dx_t(r)(x) = \sum_{i=1}^{m} X_i(x_t(h)(x)) dr_i^t$$

for $r \in \mathbb{H}$ endowed with the formal Gaussian measure $d\mu(r)$.

By Ito Calculus ([20],[49]), we can show that the semigroup $P_t$ generated by $L = 1/2 \sum_{i=1}^{m} X_i^2$ is related to the diffusion $x_t(x)$ by the formula

$$P_t(h)(x) = E[h(x_t(x))]$$

if $h$ is a continuous function on $\mathbb{R}^d$ (In such a case, the semigroup acts on continuous bounded functions on $\mathbb{R}^d$).

Malliavin idea is the following([44]): he differentiates in a generalized sense the Ito map $B \to x_t(x)$. If this Ito map is a submersion in a generalized sense (The inverse of the Malliavin matrix belongs to all the $L^p$), the law of $x_t(x)$ has a smooth density and therefore the semigroup has an heat kernel. Malliavin for that uses a heavy apparatus of differential operations on the Wiener space. Let us recall that there are several pioneering works of the Malliavin Calculus ([1], [6], [16]) motivated by mathematical physics, but only Malliavin Calculus is adapted to the study of stochastic differential equations and fit very well to the study of all measures of stochastic analysis.

Bismut ([7]) avoids to use this heavy apparatus of differential operations on the Wiener space, by using a suitable Girsanov transformation and a system of convenient stochastic differential equations in cascade associated to the original stochastic differential equation. This allows to Bismut’s way to get in a simpler way the Malliavin integration by parts for diffusions: if $(\alpha)$ is a multiindex, if $t > 0$,

$$E[h^{(\alpha)}x_t(x)] = E[h(x_t(x))Q_t^{(\alpha)}]$$

where $Q_t^{(\alpha)}$ is a polynomial in the extra coomponents of the system of stochastic differential equations in cascade and in the inverse of the Malliavin matrix.

The fact that only stochastic differential equations in cascade (therefore a system of semi-groups in cascade) appear in Bismut’s approach of the Malliavin
Calculus allows us to interpret Bismut’s way of the Malliavin Calculus in the theory of semigroup by expulsating the probabilist language in [31]. We refer to [32], [33] for reviews with some applications.

[31] uses an elementary integration by parts, which has to be optimized. The main remark is that we can adapt this elementary integration by parts for non-markovian semi-groups. It is possible to adapts Bismut’s way of the Malliavin Calculus for non-markovian semi-groups.

It is divided in two steps:

- An algebra on the semi-group. Only existences on the semigroup are required.

- Estimates on the enlarged semigroup, which are necessary because polynomial function appear in the Malliavin integration by parts which are not bounded, which are performed in the non-markovian case by the Davies gauge transform (In the Markovian case, they were done by an adaptation in semigroup on the classic Burkholder-Davies-Gundy inequalities of stochastic analysis).

Moreover, Bismut in his seminal work ([9]) has done an intrinsic integration by part formula for the Brownian motion on a manifold, which overcame the problem that in the standard Malliavin Calculus there are a lot of stochastic differential equations which represent the same semigroup. In part IV we perform an intrinsic Malliavin Calculus associated to a wide class of pseudodifferential elliptic operator, by performing a variation of the original pseudodifferential operator by a fractional power of it intrisically associated to the original operator. We do the relation between the Malliavin Calculus of Bismut type and the general theory of elliptic pseudodifferential operators.

Bismut in his seminal work [9] pointed out the relation between the Malliavin Calculus and the large deviation theory for the study of short time asymptotics of the heat-kernel associated to diffusion semi-groups. We refer to the reviews [26], [29], [53], the book [5] and the seminal work [47] for probabilist methods in short time asymptotics of semi-groups.

Let us recall quickly the main goal of large deviation theory, here of Wentzel-Freidlin type [4], [52] and [54]. We introduce a small parameter and consider the stochastic differential equation with a small parameter starting from $x$:

$$dx'_t(x) = \epsilon \sum_{i=1}^{n} X_i(x'_t)dB^i_t$$  \hspace{1cm} (16)

Wentzel-Freidlin theory allows to get estimates of the type, when $\epsilon \to 0$

$$\lim 2\epsilon^2 Log[P[x^\epsilon(x) \in 0] = - \inf_{x, (h_t(x)) \in O} \|r\|^2$$  \hspace{1cm} (17)

if $O$ is an open subset of $C([0,1], \mathbb{R}^d)$ equipped with the uniform norm. We don’t give details of the lot of technicalities in this estimate.

It is possible to adapt ([35], [37], [38], [39], [40]) Wentzel-Freidlin estimates to the case of non-markovian semi groups with the normalisation of W.K.B. analysis of Maslov school ([45]) (See [17], [27] for seminal works on W.K.B.)
analysis). The main remark is that we can get only upper-bounds, because the semi-group does not preserves the positivity in this case. The second remark is that these estimates are valid only for the semi-group, because in this case path space functional integrals are not defined (See [36] for a review and the work [11], [25], [46]). The normalizations are those classical of semi-classical analysis but the type of estimates is different. They work for the heat equation and not for the Schroedinger equation.

This allows to fullfill in this non-markovian context the beautifull request of Bismut’s book [5] and to do the marriage between the Malliavin Calculus and Wentzel-Freidlin estimates. The main difference is that we have to consider the absolute value of the heat-kernel because in such a case the semi-group does not preserve the positivity such that we get only upper-bound in the studied Varadhan type estimates (Wentzel-Freidlin estimates are still valid for the heat-kernel).

This work is a review paper of several of our works. The main novelty is part IV, which is new.

2 The case of a formal stochastic differential equation

Let us consider an elliptic differential operator of order $l$ on a compact manifold $M$ of dimension $d$. If we perturb it by a strictly lower order operator $L_p$, it results by the theory of pseudo-differential operator (which is given by the role of the principal symbol of an elliptic operator) that the qualitative behaviour (hypoellipticity..) is the same than the qualitative behavior of $L + L_p$. See [12],[18],[19] for various textbooks in analysis about this problematic.

Recently, we have introduced an elliptic operator of order $2k$ $L_0 = \sum f_i^{2k}$ where $f_i$ is an orthonormal basis of the Lie algebra of a compact Lie group $G$ of dimension $m$ with generic element $g$. $f_i$ are considered as right invariant vector fields. We have established the Malliavin Calculus of Bismut type for $L$. We consider a polynomial $Q$ of degree strictly smaller than $2k$ in the vector fields $f_i$ with constant components. We consider the total operator

$$L = L_0 + Q$$

The goal of this part, by using a small interpretation of [41] and [42] is to adapt in this present situation the strategy of [41] for diffusions. ([41] [42] have used the machinery of the Malliavin Calculus [7] translated by ourself in semi-group theory for diffusions in [31]) Malliavin matrix plays here a fundamental role in the optimization of the integration by parts in order to arrive to full Malliavin integration by parts. All formulas are formally the same if we add or not add the perturbation of the main operator.

We consider the elliptic operator on $G \times \mathbb{R}$

$$Q + \sum_i f_i^{2k} + \sum r_{i,t} f_i \frac{\partial}{\partial u} + \frac{\partial^{2k}}{\partial u^{2k}} = \tilde{L}_t$$

(19)
It generates by elliptic theory a semi-group on $C_b(G \times \mathbb{R})$, the space of bounded continuous function on $G \times \mathbb{R}$ endowed with the uniform norm.

**Theorem 1** (Elementary integration by parts formula). We have if $h$ is smooth with compact support

$$\int_0^t P_{t-s} \sum h_{s,i} e_i P_s [h] ds = \hat{P}_t^h [uh](.,0)$$

**Proof:** It is the same proof than the proof of Theorem 3 of [42]. ◇

Let $V = G \times M_d$. $M_d$ is the space of symmetric matrices on $\text{LieG}$. $(x, v) \in V$. $v$ is called the Malliavin matrix. We consider

$$\hat{X}_0 = (0, \sum < g^{-1} f_i, . >^2)$$

We consider the Malliavin generator (We skip the problems of signs)

$$\hat{L} = Q + \sum f_i^{2k} - \hat{X}_0$$

**Theorem 2** $\hat{L}$ spans a semi-group. $\hat{P}_t$ called the Malliavin semi-group on $C_b(M)$.

**proof** It is the same proof of theorem 4 of [42] since $Q$ is a polynomial with constant coefficients in the $f_i$ and $L$ generates a $C_b(G)$ semi-group. The proof leads to some difficulties because the Malliavin operator is not the perturbation of an elliptic operator and uses the Volterra expansion. ◇

The Malliavin semi-group will allow to us to optimize the elementary integration by parts of theorem 2. We have the main theorem of this paper:

**Theorem 3** (Malliavin) If the Malliavin condition holds

$$|\hat{P}_t|^{|v^{-p}}(g,0) < \infty$$

for all integer positive integer $p$, $P_t$ has an heat-kernel.

**Proof:** It is the same proof as in the beginning of the proof of theorem 6 of [42]. Under Malliavin assumption, we can optimize the elementary integration by parts of Theorem 2, in order to get, according the framework of the Malliavin Calculus, the inequality for any smooth function $h$ on $G$

$$|P_t[< dh, f_i >]| \leq C \|h\|_\infty$$

◇

**Remark:** Let us explain quickly the philosophy of this theorem, when there is no perturbation term. We consider a set of path in $\mathbb{R}^d$ denoted $r_t^i$ which
represent the semi-group associated to $\sum_i \frac{\partial^2}{\partial u_i^2}$. We don’t enter in the problem of signs. We consider the formal stochastic differential equation

$$dx_t(r)(e) = \sum_i f_i dr^i_t$$

issued from $e$. Formally, this represent the semi-group $P_t$ without the perturbation term

$$P_t[h](e) = "E"[f(x_t(e))]$$

Malliavin assumption express in some sense that the ”Ito” map $r^i \rightarrow x_t(e)$ is a submersion.

By this inequality, we deduce according the framework of the Malliavin Calculus that

$$P_t[h](e) = \int_G h(g)p_t(e, g)dg$$

for a non strictly positive heat-kernel $p_t$ (dg) denotes the normalized Haar mesure on $G$), if the Malliavin assumption is satisfied.

**Theorem 4** Under the previous elliptic assumptions,

$$|\hat{P}_t|||v^{-p}|||(g_0, 0) < \infty$$

if $t > 0$

**Proof** It is the same proof than the proof of theorem 8 of [42]. It is based upon the initial strategy to invert the Malliavin matrix in stochastic analysis by slicing the time interval in small time intervals. Only the main part of the generator plays the main role in this strategy because we are in an elliptic case.

We can iterate the integration by parts formulas, by introducing a system of semi-groups in cascade. We deduce the theorem

**Theorem 5** If $t > 0$ the semi group $P_t$ has a smooth heat kernel

$$P_t([h])(g) = \int_G p_t(g, g')dg'$$

The main remark is that the heat kernel can change of sign. This theorem is classical in analysis [51] but it enters in our general strategy to implement stochastic tools in the general theory of linear semi-groups.

In order to simplify the computation, we have used the symmetry of the group. In the next part, we will use fully the symmetry of the group to simplify the computations.
3 The full use of the symmetry of the group

Let us recall what is a pseudodifferential operator on $\mathbb{R}^d$ ([12], [17], [18]). Let be a smooth function function from $\mathbb{R}^d \times \mathbb{R}^d$ into $\mathbb{R} a(x, \xi)$. We suppose that

$$\sup_{x \in \mathbb{R}^d} |D_x^r D_\xi^l a(x, \xi)| \leq C|\xi|^{m-l} + C \quad (30)$$

We suppose that

$$\inf_{x \in \mathbb{R}^d} |a(x, \xi)| \geq C|\xi|^{m'} \quad (31)$$

for $|\xi| > C$ for a suitable $m' > 0$. Let $\hat{h}$ the fourier transform of the continuous function $h$. We consider the operator $L$ defines on smooth function $h$ by :

$$\mathcal{L}h(x) = \int_{\mathbb{R}^d} a(x, \xi)\hat{h}(\xi)d\xi \quad (32)$$

$L$ is said to be a pseudodifferential operator elliptic of order larger than $m'$ with symbol $a$. This property is invariant if we do a diffeomorphism on $\mathbb{R}^d$ with bounded derivatives at each order. This remark allows to define by using charts a pseudodifferential operator elliptic of order larger than $m'$ on a compact manifold $M$.

Let $f^i$ be a basis of $T_eG$. We can consider as rightinvariant vector fields. This means that if we consider the action $R_{g_0} h \to (g \to h(gg_0))$ on smooth function $h$ on $G$, we have

$$R_{g_0}(f^i h) = f^i(R_{g_0} h) \quad (33)$$

We consider a rightinvariant elliptic pseudodifferential positive elliptic operator $L$ of order larger than $2k$ on $G$. It generates by elliptic theory a semi group $P_t$ on $L^2(dg)$ and even on $C_b(G)$ the space of continuous functions on $G$ endowed with the uniform norm.

**Theorem 6** If $t > 0$,

$$P_th(g_0) = \int_G p_t(g_0, g)h(g)dg \quad (34)$$

where $g \to p_t(g_0, g)$ is smooth if $h$ is continuous.

This theorem is classical in analysis, but it enters in our general program to implement stochastic analysis tool in the theory of Non-Markovian semi-group. See the review [36] for that. See [41], [42] for another presentation where the Malliavin Matrix plays a key role. Here we don’t use the Malliavin matrix. See [43] for the case of rightinvariant differential operators. The proof is divided in two steps.
3.1 Algebraic scheme of the proof: Malliavin integration by parts

We consider the family of operators on $C^\infty(G \times \mathbb{R}^n)$:

\[ \tilde{L}_t^n = L + \sum_{i=1}^n f^i \partial \alpha_i^t + \sum_{i=1}^n \partial^2 \alpha_i^t \quad (35) \]

\( \alpha_i^t \) are smooth function from $\mathbb{R}^+ \to \mathbb{R}$. By elliptic theory, $\tilde{L}_t^n$ generates a semi-group $\tilde{P}_t^n$ on $C^\infty(G \times \mathbb{R}^n)$. This semi-group is time inhomogeneous.

\[ \tilde{P}_t^{n+1}[h(g)h^n(u)](\ldots, 0) = \int_0^t \tilde{P}_{t,s}^{n+1}[f^{j+1} \alpha_{s+1} + \tilde{P}_s^n[h(g)h^n(u)]](\ldots) \quad (36) \]

Moreover

\[ \tilde{P}_t^{n+1}[uh(.)h^n(.)](\ldots, u_{n+1}) = \tilde{P}_t^{n+1}[uh(.)h^n(.)](\ldots, 0) + \tilde{P}_t^n[h(.)h^n(.)](\ldots, 0)u_{n+1} \quad (37) \]

\( h \) is a function of \( g \), \( h^n \) a function of \( u_1, \ldots, u_n \). This comes from the fact that $\partial / \partial u_{n+1}$ commute with the considered operator.

Therefore the two sides of (37) satisfy the same parabolic equation with second-member. We deduce that

\[ \tilde{P}_t^{n+1}[u_{n+1} \prod_{j=1}^n u_j h(.)](\ldots, 0) = \int_0^t ds \tilde{P}_{t,s}^{n+1}[f^{j+1} \alpha_{s+1} \tilde{P}_s^n[h \prod_{j=1}^n u_j]](\ldots) \quad (38) \]

This is an integration by parts formula. We would like to present this formula in a more appropriate way for our object.

We consider the operator

\[ \mathcal{L}^n = L + \sum_{j=1}^n \partial^2 k \quad (39) \]

It generates a semi-group $\mathcal{P}_t^n$. In the sequel we will skip the problem of sign coming if $k$ is even or not.

We introduce a suitable generator

\[ \tilde{R}_t^{n+1} = \mathcal{L}^n + F_s \quad (40) \]

by taking care of the relation $[f^i, f^j] = \sum_k \lambda_{ij}^k f^k$. It is an operator of the type studied. It generates therefore a time inhomogeneous semi-group $\tilde{Q}_t^n$. Therefore the integration by parts formula (39) can be written in the more suitable way

\[ \tilde{P}_t^{n+1}[u_{n+1} \prod_{j=1}^n u_j h(.)](\ldots, 0) = \int_0^t ds \tilde{P}_{t,s}^{n+1}[f^{j+1} \tilde{P}_s^n[h \prod_{i=1}^n u_i]](\ldots) + \int_0^t ds \tilde{P}_{t,s}^{n+1}[\tilde{Q}_s^n[h \prod_{i=1}^n u_i]](\ldots) \quad (41) \]
We do the following recursion hypothesis on \( l \):

**Hypothesis (l)** There exists a positive real \( r_l \) such that if \((\alpha)\) is a multiindex of length smaller than \( l \)

\[
|\tilde{P}^n_t[f^{(\alpha)}h \prod_{i=n}^n u_i](g,v)| \leq Ct^{-r_l}\|h\|_{\infty}(1 + \prod_{i=n}^n |v_i|) \tag{42}
\]

where \( \|.\|_{\infty} \) is the uniform norm of \( h \).

It is true for \( l = 1 \) by (39) and the estimates which follow.

If it is true for \( l \), it is still true for \( l + 1 \), by using (42) for \( f^{(\alpha)}h \) and taking \( \alpha_{n+1}' = s_r \)

By choosing suitable \( \alpha'_j \), we have according the framework of the Malliavin Calculus for any multiindex \((\alpha)\)

\[
|P^n_t[f^{(\alpha)}h](g_0)| \leq C(\alpha)\|h\|_{\infty} \tag{43}
\]

in order to conclude.

### 3.2 Estimates: the Davies gauge transform

We do as in [43] (26). The problem is that in \( \tilde{P}^n_t[h \prod_{j=1}^n u_j](\ldots) \) the test function \( u_j \) are not bounded and that \( \tilde{P}^n_t \) acts only on \( C_b(G \times \mathbb{R}^n) \). We do as in [3] the Davies gauge transform \( \prod_{i=1}^n g(u_i) \) where

\[
g(u) = (|u|) \tag{44}
\]

if \( u \) is big and \( g \) is smooth.

This gauge transform acts on the original operator by the simple formula \((\prod_{i=1}^n g(u_i))^{-1}\tilde{L}_t^n((\prod_{i=1}^n g(u_i)).)\). On the semi group it acts as

\[
(\prod_{i=1}^n g(.))^{-1}\tilde{P}^n_t[\prod_{i=1}^n g(u_i)h(.)h^n(.)][\ldots] \tag{45}
\]

But

\[
(g(u_i))^{-1}\frac{\partial}{\partial u_i}(g(u_i).) = \frac{\partial}{\partial u_i} + C(u_i) \tag{46}
\]

where the potential \( C(u_i) \) is smooth with bounded derivatives at each order. Therefore the transformed semi-group act on \( C_b(G \times \mathbb{R}^n) \).

**Remark** We can consider as particular case ([43]) Let \( G \) be a compact connected Lie group, with generic element \( g \) endowed with its biinvariant Riemannian structure and with its normalized Haar measure \( dg \). \( e \) is the unit element of \( G \).

Let \( f^i \) be a basis of \( T_eG \). We can consider as rightinvariant vector fields. This means that if we consider the action \( R_{g_0} h \rightarrow (g \rightarrow h(gg_0)) \) on smooth function \( h \) on \( G \), we have

\[
R_{g_0}(f^i h) = f^i(R_{g_0} h) \tag{47}
\]
Let be $\xi^{(\alpha)} = \xi^{\alpha_1}...\xi^{|\alpha|}$ and let be $f^{(\alpha)} = f^{\alpha_1}...f^{\alpha_k}$. $(\alpha)$ is a multi-index of length $|\alpha|$.

We consider a matrix $a_{\alpha,\beta}$ for multindices of length $k$, which is supposed symmetric strictly positive.

We consider the operator

\[ L = \sum_{(\alpha),(\beta)} f^{(\alpha)} a_{(\alpha),(\beta)} f^{(\beta)} \]  

(48)

According [51], $(-1)^k L$ is a positive symmetric densely elliptic defined operator on $L^2(G)$, which generates by elliptic theory a semi-group acting on $C_b(G)$, the space of continuous function on $G$. In such a case, we have an heat-kernel associated to the semi-group (See [43]). The case of a rightinvariant differential operator has exactly the same proof than the case of theorem 6, where the details will be presented elsewhere.

4 The case of an intrinsic variation

Let $L$ be a strictly positive self-adjoint operator on a compact manifold $M$. We suppose that $L$ is a pseudo-differential elliptic operator of order $l \geq 2k$ for an integer $k \geq 1$. It generates a contraction semi-group on $L^2(M)$ and by ellipticity a semi-group on $C_b(M)$.

**Theorem 7** There is an heat-kernel $p_t(x,y)$ associated to $P_t$. If $t > 0$

\[ P_t(f)(x) = \int_M p_t(x,y)f(y)dy \]  

(49)

where $y \rightarrow p_t(x,y)$ is smooth.

The proof is divided in two steps:

4.1 Algebraic scheme of the proof: Malliavin integration by parts

Let $\alpha$ belonging to $]0,1[$. The fractional power [50] $L^\alpha$ is still a strictly positive pseudodifferential operator elliptic of order $\alpha l$, which commutes with $L$. We skipp up later the problem if $k$ is even or not. We consider the operator on $C^\infty(M \times \mathbb{R}^n)$

\[ \bar{L}^\alpha_s = L + s^\alpha L^\alpha \sum_i \frac{\partial}{\partial u_i} + \sum_{i=1}^n \frac{\partial^{2k}}{\partial u_i^{2k}} \]  

(50)

It is an elliptic operator of order $2k$ on $M \times \mathbb{R}^n$. The main part

\[ \mathcal{T}^\alpha = L + \sum_{i=1}^n \frac{\partial^{2k}}{\partial u_i^{2k}} \]  

(51)
is positive and is essentially self-adjoint. Therefore the main part generates a semi-group on \( C_b(M \times \mathbb{R}^n) \). This remains true for \( \tilde{L}^n \) because \( \tilde{L}^n \) is a perturbation of \( L^n \) by a strictly lower operator. We call this semi-group \( \tilde{P}^n_t \).

The main remark is that \( L^\alpha \) commutes with \( \tilde{L}^n \) such that

\[
L^\alpha \tilde{P}^n_t = \tilde{P}^n_t L^\alpha
\]

According the beginning of the previous part, we get the elementary integration by part

\[
\tilde{P}^{n+1}_t f \left( \prod_{i=1}^n u_i \right) (x, v, 0) = \int_0^t \tilde{P}^n_{t-s} \left[ s^r L^\alpha \tilde{P}^n_s f \left( \prod_{i=1}^n u_i \right) \right](x, v_i) = \\
\tilde{P}^n_t \left[ L^\alpha f \left( \prod_{i=1}^n u_i \right) \right] (x, u_i) \int_0^t s^r ds
\]

Suppose by induction on \( l \) that

\[
|\tilde{P}^n_t [(L^\alpha)^l f \left( \prod_{i=1}^n u_i \right)](x, v_i)| \leq C t^{-r(l)} \|f\|_\infty (1 + \prod_{i=1}^n |v_i|)
\]

By applying the elementary integration by parts (54) to \((L^\alpha)^l f\), and choosing \( r = r(l)\), we deduce our result. Therefore we have the inequality

\[
|P_t [(L^\alpha)^l f](x)| \leq C t^{-r(l)} \|f\|_\infty
\]

The result follows from the fact that \( L^\alpha \) is an elliptic operator.

### 4.2 Estimates: the Davies gauge transform

We do as in [43] (26). The problem is that in \( \tilde{P}^n_t [h \prod_{j=1}^n u_j](\ldots) \) the test function \( u_j \) are not bounded and that \( \tilde{P}^n_t \) acts only on \( C_b(G \times \mathbb{R}^n) \). We do as in [35] the Davies gauge transform \( \prod g(u_i) \) where

\[
g(u) = (|u|)
\]

if \( u \) is big and \( g \) is smooth strictly positive.

This gauge transform acts on the original operator by the simple formula \((\prod_{i=1}^n g(u_i))^{-1} \tilde{L}^n_s ((\prod_{i=1}^n g(u_i)) \ldots)\). On the semi group it acts as

\[
\left( \prod_{i=1}^n g(.) \right)^{-1} \tilde{P}^n_t \left[ \prod_{i=1}^n g(u_i) h(\ldots) h^n(\ldots) \right](\ldots)
\]

But

\[
(g(u_i))^{-1} \frac{\partial}{\partial u_i} (g(u_i)) = \frac{\partial}{\partial u_i} + C(u_i)
\]
where the potential $C(u_i)$ is smooth with bounded derivatives at each order. Therefore the transformed semi-group act on $C_b(G \times \mathbb{R}^n)$. It remains to choose

$$h^n(u_i) = \prod_{j=1}^{n} \frac{u_j}{g(u_j)}$$

in order to conclude. We deduce the bound:

$$|\tilde{P}_t^n||h^n\prod_{j=1}^{n} |u_j||(.; v.) \leq C(\|h\|_\infty(1 + \prod_{i=n}^{n} |v_i|))$$

where $|\tilde{P}_t^n|$ is the absolute value of the semi-group $\tilde{P}_t^n$.

Remark: We could show that $(x, y) \rightarrow p_t(x, y)$ is smooth if $t > 0$ by the same argument.

Remark: We can replace the hypothesis $L$ strictly positive by the hypothesis $L$ positive by replacing $L^\alpha$ by $(L + CI_d)^\alpha$ where $C > 0$.

5 Wentzel-Freidlin estimates for the semi-group only

We consider a differential operator of order $2k$ on the compact manifold $M$ which is supposed elliptic of order $2k$ and strictly positive. We suppose we can write it as

$$L = \sum_{j=0}^{2k} \sum_{i=0}^{r(j)} (X_{i,j})^j$$

where $X_{i,j}$ are smooth vector fields on $M$. The ellipticity assumption states that

$$\sum_{i=0}^{r(2k)} \langle X_{i,2k}, \xi \rangle^{2k} = H(x, \xi) \geq C|\xi|^{2k}$$

To the Hamiltonian $H$, we introduce the Lagrangian

$$L(x, p) = \sup_{\xi} \langle p, \xi \rangle - H(x, \xi)$$

We get the estimate

$$-C + C|p|^\frac{2k}{2k-1} \leq L(x, p) \leq C + |p|^\frac{2k}{2k-1}$$

for some strictly positive constants $C$.

If $\phi$ is a continuous piecewise differentiable path on $M$, we put:

$$S(\phi) = \int_0^1 L(\phi(t), d/dt\phi(t))dt$$

13
and we put
\[ l(x, y) = \inf_{\phi(0) = x, \phi(1) = y} S(\phi) \] (66)

By Ascoli theorem, \((x, y) \to l(x, y)\) is a continuous function on \(M \times M\).

**Theorem 8 (Wentzel-Freidlin)** If \(O\) is an open ball of \(M\), we have when \(t \to 0\)
\[ \lim_{t \to 0} \frac{1}{2k-1} \log |P_t|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (67)

**Proof:** We put \(\epsilon = t^{\frac{1}{2k-1}}\). According to the normalisation of Maslov school [37], we consider the semi-group \(P_\epsilon\) associated to \(L_\epsilon = \epsilon^{2k-1}L\). Moreover
\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)

The main ingredient is:

**Lemma 9** For all \(\delta > 0\), all \(C\), there exists \(s_\delta\) such that if \(s < s_\delta\)
\[ |P_\epsilon^s|[1_{B(x, \delta^\epsilon)}](x) \leq \exp[-C/\epsilon] \] (70)
where \(B(x, \delta)\) is the ball of radius \(\delta\) and center \(x\).

**Proof of the lemma** We imbedd \(M\) in a linear space. We consider the semi-group \(Q_\epsilon\) associated to \(L_\epsilon = \epsilon^{2k-1}L\). Moreover
\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)

The main ingredient is:

**Lemma 9** For all \(\delta > 0\), all \(C\), there exists \(s_\delta\) such that if \(s < s_\delta\)
\[ |P_\epsilon^s|[1_{B(x, \delta^\epsilon)}](x) \leq \exp[-C/\epsilon] \] (70)
where \(B(x, \delta)\) is the ball of radius \(\delta\) and center \(x\).

**Proof of the lemma** We imbedd \(M\) in a linear space. We consider the semi-group \(Q_\epsilon\) associated to \(L_\epsilon = \epsilon^{2k-1}L\). Moreover
\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)

The main ingredient is:

**Lemma 9** For all \(\delta > 0\), all \(C\), there exists \(s_\delta\) such that if \(s < s_\delta\)
\[ |P_\epsilon^s|[1_{B(x, \delta^\epsilon)}](x) \leq \exp[-C/\epsilon] \] (70)
where \(B(x, \delta)\) is the ball of radius \(\delta\) and center \(x\).

**Proof of the lemma** We imbedd \(M\) in a linear space. We consider the semi-group \(Q_\epsilon\) associated to \(L_\epsilon = \epsilon^{2k-1}L\). Moreover
\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)

The main ingredient is:

**Lemma 9** For all \(\delta > 0\), all \(C\), there exists \(s_\delta\) such that if \(s < s_\delta\)
\[ |P_\epsilon^s|[1_{B(x, \delta^\epsilon)}](x) \leq \exp[-C/\epsilon] \] (70)
where \(B(x, \delta)\) is the ball of radius \(\delta\) and center \(x\).

**Proof of the lemma** We imbedd \(M\) in a linear space. We consider the semi-group \(Q_\epsilon\) associated to \(L_\epsilon = \epsilon^{2k-1}L\). Moreover
\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)

The main ingredient is:

**Lemma 9** For all \(\delta > 0\), all \(C\), there exists \(s_\delta\) such that if \(s < s_\delta\)
\[ |P_\epsilon^s|[1_{B(x, \delta^\epsilon)}](x) \leq \exp[-C/\epsilon] \] (70)
where \(B(x, \delta)\) is the ball of radius \(\delta\) and center \(x\).

\[ P_t = P_{t1}^\epsilon \] (68)
where \(P_s^\epsilon\) is associated to \(tL\) ([10]) The result will arise if we show when \(\epsilon \to 0\)
\[ \lim_{\epsilon \to 0} \epsilon \log |P_\epsilon^s|(1_O)(x) \leq - \inf_{y \in O} l(x, y) \] (69)
the previous part in order to show that the measure $\mu_\epsilon$ has a bounded density $q_\epsilon(x,.)$ when $\epsilon \to 0$.

Let $R$ be a differential operator of order $l$. We have

$$\int_M g(x)RP_1^\epsilon[h](x)dx = \int_{M \times M} \epsilon(x)h(y)R_\epsilon p_1^\epsilon(x,y)dxdy \quad (76)$$

By symmetry

$$p_1^\epsilon(x,y) = p_1^\epsilon(y,x) \quad (77)$$

Then

$$\int_M g(x)RP_1^\epsilon[h](x)dx = \int_M h(y)P_1^\epsilon[Rg](y)dy \quad (78)$$

By the previous remark

$$|P_1^\epsilon[Rh](y)| \leq \frac{C}{\epsilon^{2^k-1}}\|h\|_\infty \quad (79)$$

Therefore

$$\left| \int_M g(x)RP_1^\epsilon[h](x)dx \right| \leq \frac{C}{\epsilon^{2^k-1}}\|g\|_\infty\|h\|_\infty \quad (80)$$

We deduce that

$$|RP_1^\epsilon[h](x)| \leq \frac{C}{\epsilon^{2^k-1}}\|h\|_\infty \quad (81)$$

We deduce a bound of $R_\epsilon P_1^\epsilon$

$$|R_\epsilon P_1^\epsilon h(x)| \leq \frac{C}{\epsilon^{2^k-1}}\|h\|_\infty \quad (82)$$

We apply Volterra expansion to $Q_1^\epsilon$. We get

$$|Q_1^\epsilon f| \leq |P_1^\epsilon f| + \sum_{i=1}^\infty \left| \int_{\Delta_i(s)} I_{s_1...s_l} ds_1...ds_l \right| \quad (83)$$

where $\Delta_i(s)$ is the simplex $0 < s_1 < ... < s_l < s$ and

$$I_{s_1...s_l} = p_1^\epsilon(R_\epsilon + H/\epsilon)...p_1^\epsilon(R_\epsilon + H/\epsilon)P_1^\epsilon_{x\epsilon-s_{l-1}} h \quad (84)$$

We deduce a bound of $\left| \int_{\Delta_i(s)} I_{s_1...s_l} ds_1...ds_l \right|$ by

$$\frac{|\xi|^{2l}}{\epsilon^l} \int_{\Delta_i(s)} \prod_{i=1}^l (s_{i+1} - s_i)^{-\frac{2l}{2^k}} ds_1...ds_l = \frac{|\xi|^{2l}}{\epsilon^l} I_l(s) \quad (85)$$

We suppose by induction that

$$I_l(s) = \alpha_l s^{(1+\beta_s)} \quad (86)$$
where $\beta_k \in [-1,0[$. It is still true by the recursion formula

$$I_{l+1}(s) = \int_0^s I_l(u)(s-u)^{-2k-1} \frac{du}{2k}$$  \hspace{1cm} (87)

We deduce the bound

$$\alpha_l \leq \frac{C_l}{l!}$$  \hspace{1cm} (88)

Therefore

$$|Q_s^x h(x)| \leq \exp[Cs|\xi|^2k/\epsilon]$$  \hspace{1cm} (89)

It remains to remark that we have the bound

$$|P_{s}^{\xi}[1_{B(x,\delta^y)}](x) \leq \exp[-\frac{C\delta|\xi|}{\epsilon} + Cs|\xi|^2k/\epsilon]$$  \hspace{1cm} (90)

and to extremize in $|\xi|$ to conclude.\end{small}

**End of the proof of theorem 9** We proceed as in Freidlin-Wentzel book [54] and as in [35],[38], and [39]. We slice the time interval $[0,1]$ in a finite numbers of time intervals $[s_i, s_{i+1}]$ where we can apply the previous lemma. We deduce a positive measure on the set of polygonal paths, where we can repeat exactly the considerations of [35].

**Remark:** This estimate is a semi-classical estimate with different type of estimates of W.K.B. estimates a la Maslov and with a different method. We consider in W.K.B. estimate a symbol of an operator $a(x,\xi)$ and we consider the generator $L_c$ associated with the normalized symbol (a la Maslov) $1/e\alpha(x,\epsilon\xi)$. Let us suppose that $L_c$ generates a semi-group $P_t^1$. The object of WKB method is to get **precise** estimates of the semi-group $P_t^1$ when $\epsilon \to 0$. For that people look at a formal asymptotic expansion (we omit to write the initial conditions) of $P_t^1$ of the type

$$\epsilon^{-\tau} \exp[-l(y)/\epsilon] \sum \epsilon^l C_l(y)$$  \hspace{1cm} (91)

The function $l$ satisfy a highly non-linear equation (the Hamilton-Jacobi-Belman equation) and $C_l(y)$ satisfy formally a system of linear partial differential equation in cascade. The cost function in theorem $l(x,y)$ is solution of the highly non-linear Hamilton-Jacobi-Belman equation, which is difficult to solve. Instead of precise asymptotics, we are interested by logarithmic estimates which are totally different with a method totally different. On the other hand, generally semi-classical asymptotics considers the case of the Schroedinger equation instead of the heat semi-group.

On $\mathbb{R}^d$ we can speak without any difficulty of the symbol of an operator. Poisson processes, Lévy processes and jump processes are more or less generated by pseudodifferential operators whose generator satisfy the maximum principle (See [10], [21], [22], [13], [24], [28]). We will present pseudodifferential operators with a type of compensation of stochastic analysis which do not satisfy the maximum principle. The end of this part is extracted from [35] and [40]. Let us consider the generator on $C_\infty(\mathbb{R}^d)$

$$Lf(x) = (-)^{l+1} \int_{\mathbb{R}^d} (f(x+y) - f(x) - \sum_{i=1}^{2l} <y^{\otimes i},D^i f(x)>) \frac{h(x,y)}{|y|^{2l+1+\alpha}} dy$$  \hspace{1cm} (92)
\( \alpha \in ]-1,0[ \) \( h(x,y) = 0 \) if \( |y| > C \) and \( h \geq 0 \). The measure \( \frac{h(x,y)}{|y|^{l+1+\alpha}} \, dy \) is called the Lévy measure.

**Theorem 10** If \( h(x,0) = 1 \), \( L \) is an elliptic pseudo-differential generator.

**Definition 11** If \( h(x,y) = h(y) \), we will say that \( L \) is a generalized Lévy generator.

**Theorem 12** Suppose that \( L \) is of Lévy type and that \( h(y) = h(-y) \). \( L \) is positive symmetric, and therefore admits by ellipticity a selfadjoint extension on \( L^2(\mathbb{R}^d) \), which generates a contraction semi group on \( L^2(\mathbb{R}^d) \) which is still a semi-group on \( C_b(\mathbb{R}^d) \).

**Remark:** The symbol \( a(x,\xi) \) of the generator is given by

\[
(-1)^{l+1} \int_{\mathbb{R}^d} \left( \exp \left[ \sqrt{-1} \langle y,\xi \rangle \right] - \sum_{i=1}^{2l} \frac{\left( \sqrt{-1} \langle \xi, y \rangle \right)^i}{i!} \right) \frac{h(x,y)}{|y|^{2l+1+\alpha}} \, dy \tag{93}
\]

The Hamiltonian associated is the symbol in real phase. Let us consider a generator of Lévy type of the previous theorem: it is

\[
(-1)^{l+1} \int_{\mathbb{R}^d} \left( \exp \langle y,\xi \rangle - \sum_{i=1}^{l} \frac{\langle \xi, y \rangle^2i}{2i!} \right) \frac{h(y)}{|y|^{2l+1+\alpha}} \, dy \tag{94}
\]

The Hamiltonian is a smooth convex function equals to 1 in 0. Associated to it, we consider the Lagrangian:

\[
L(p) = \sup_{\xi} \langle \xi, p \rangle - H(\xi) \tag{95}
\]

If \( t \to \phi_t \) is a piecewise differentiable continuous curve in \( \mathbb{R}^d \), we consider its action \( \int_0^1 dt L(\phi_t, d/dt\phi_t) = S(\phi) \) We introduce the control function

\[
l(x,y) = \inf_{\phi_0 = x; \phi_1 = y} S(\phi) \tag{96}
\]

Let us recall that \( (x,y) \to l(x,y) \) is positive finite continuous.

We consider the generator associated to \( 1/\epsilon a(\epsilon \xi) \). This corresponds in the classical case of jump process where the compensation is only of one term to the case of a jump process with more and more jumps which are more and more small [54]. We consider the generator \( L^\epsilon \) associated to \( 1/\epsilon a(\epsilon \xi) \). It generates a semi-group \( P_t^\epsilon \). We get:

**Theorem 13** Wentzel-Freidlin ([35], [40]). When \( \epsilon \to 0 \), we get if \( O \) is an open ball of \( \mathbb{R}^d \) if \( l + 1 \) is even:

\[
\lim_{\epsilon \to 0} \log |P_t^\epsilon[1_O]|(x) \leq - \inf_{y \in O} l(x,y) \tag{97}
\]

**Remark:** For this type of operator, Wentzel-Freidlin estimates are not related to short time asymptotics.
6 Application: some Varadhan estimates

This part follows closely [43]. Only the mechanism of the integration by part is different from [39]. For large deviation estimates with respect of W.K.B normalization at the manner of Maslov [45] for Non-Markovian operators, we refer to [38] for instance.

Let us consider the Hamiltonian function from $T^*(G)$ into $\mathbb{R}^+$

$$H(g, \xi) = \sum_{|\alpha|=k,|\beta|=k} \langle f^{(\alpha_1)}, \xi \rangle < \cdots < \langle f^{(\alpha_k)}, \xi \rangle < a_{(\alpha),(\beta)} \langle f^{(\beta_1)}, \xi \rangle < \cdots < \langle f^{(\beta_k)}, \xi \rangle$$

(98)

$H(g, p)$ is positive convex in $p$. According the theory of large deviation, we consider the associated Lagrangian

$$L(g, \xi) = \sup_\xi (<\xi, p> - H(g, \xi))$$

(99)

If $t \to \phi_t$ is a curve in the group, we consider its action

$$\int_0^1 dt L(\phi_t, d/dt \phi_t) = S(\phi)$$

We introduce the control function

$$l(g_0, g_1) = \inf_{\phi_0 = g_0, \phi_1 = g_1} S(\phi)$$

(100)

Let us recall that $(g_0, g_1) \to l(g_0, g_1)$ is positive finite continuous.

We have shown in the previous part that if we consider a small parameter $\epsilon$ and if we consider the generator $\epsilon^{2k-1}L$ and the semi group $P_t^\epsilon$ associated and if $g_0$ and $g_1$ are not closed, we get for any small ball centered in $g_1$ uniformly:

$$\lim_{\epsilon \to 0} \epsilon Log |P_t^\epsilon(1O)(g_0)| \leq - \inf_{g_1 \in O} l(g_0, g_1)$$

(101)

where $|P_t^\epsilon|$ is the absolute value of the semi-group (See [38]). See for that the previous part.

But $P_t = P_t^1$ where $P_t^1$ is the semi group associated to $tL$ (See [15]). We put $\epsilon = t^{1/2k-1}$ such that

$$\lim_{t \to 0} t^{1/2k-1} Log |P_t(1O)(g_0)| \leq - \inf_{g_1 \in O} l(g_0, g_1)$$

(102)

We consider $\chi$ a smooth positive function equals to 0 outside $O$ and equals to 1 on a small open ball centered in $g_1$ smaller than 1.

We would like to apply the mechanism of Malliavin integration by parts to the measure

$$h \to P_t[h\chi](g_0)$$

(103)

such that

$$|P_t[\chi f^{(\alpha)}h](g_0)| \leq C t^{(-r(\alpha))} \exp[-\frac{l(g_0, g_1) + \delta}{t^{1/2k-1}}] ||h||_\infty$$

(104)

for a small $\delta$. Since (104) is true, we have:

**Theorem** When $t \to 0$

$$\lim_{t \to 0} t^{1/2k-1} Log |P_t(g_0, g_1)| \leq -l(g_0, g_1)$$
