Signed Mahonian polynomials
for classical Weyl groups

Riccardo Biagioli

September 1, 2018

Abstract

The generating functions of the major index and of the flag-major index, with each of the one-dimensional characters over the symmetric and hyperoc-tahedral group, respectively, have simple product formulas. In this paper, we give a factorial-type formula for the generating function of the $D$-major index with sign over the Weyl groups of type $D$. This completes a picture which is now known for all the classical Weyl groups.

1 Introduction

Sums of the form

$$\sum_{w\in W} \chi(w)q^{\text{des}(w)},$$

where $W$ is a classical Weyl group, $\chi$ is a one-dimensional character of $W$, and $\text{des}(w)$ is the number of descents of $w$ as Coxeter group element, have been investigated by Reiner [16]. In the case of the symmetric group, when $\chi$ is the trivial character this sum is the well known Eulerian polynomial [9], and when $\chi$ is the sign character then it is the signed Eulerian polynomial studied by Désarménien and Foata [11], and Wachs [19]. Analogously, consider the sum

$$\sum_{w\in W} \chi(w)q^{\text{maj}_W(w)},$$

where $\text{maj}_W$ denotes a suitable Mahonian statistic on the corresponding group $W$. Recall that a statistic on a Coxeter group is said to be Mahonian if it is equidistributed
with the length function on the group. In the case of the symmetric group, if \( \chi \) is
the trivial character, the sum in (1) is nothing but the Poincaré polynomial of \( S_n \),
which, as is well known, admits a nice product formula for every finite Coxeter group
(see e.g., [14]). Otherwise, if \( \chi \) is the sign character, this sum corresponds to the
signed Mahonian polynomial studied by Gessel and Simion [19], who found an elegant
product formula for it in terms of \( q \)-factorials. Recently, several extensions of this
result have been given by Adin, Gessel and Roichman [4]. In particular they have
provided nice formulas for the polynomial in (1) in the case of the hyperoctahedral
group \( B_n \) equipped with the Mahonian statistic “fmaj”, the flag-major index, which
was defined by Adin and Roichman in [1].

In this paper we deal with Weyl groups of type \( D \) together with the \textit{D-major
index} “Dmaj”, defined by the present author and Caselli in [5]. The \( D \)-major index
is a Mahonian statistic that has the analogous role for \( D_n \), as \( \text{maj} \) has for \( S_n \) and fmaj
for \( B_n \). Moreover it shares with them very nice algebraic properties (see [13],[1],[2, 3]
and [5, 6]). Like the symmetric group, \( D_n \) has only two one-dimensional characters,
the trivial and the sign. In the case of the trivial character the corresponding sum of
(1) is again the Poincaré polynomial of \( D_n \). In the case of the sign character we give a
factorial-type formula for the signed Mahonian polynomial of type \( D \), extending the
formulas previously mentioned. Toward this end, we define a natural sign-reversing
involution on \( B_n \), in the “style of Wachs” (see [19]), that is fmaj preserving. We use
this involution, first to give an easy proof of the Adin-Gessel-Roichman formula for
the signed Mahonian polynomial for \( B_{2n} \), and then to derive from the latter formula
the analogue for \( D_n \). This completes a picture for the generating functions for the
major index with one-dimensional characters over the classical Weyl groups \( S_n, B_n, \)
and \( D_n \).

2 Preliminaries and Notation

In this section we give some definitions, notation and results that will be used in
the rest of this work. For \( n \in \mathbb{N} \) we let \([n] := \{1, 2, \ldots, n\} \) (where \([0] := \emptyset \)). Given
\( n, m \in \mathbb{Z}, n \leq m \), we let \([n, m] := \{n, n+1, \ldots, m\} \). We let \( \mathbb{P} := \{1, 2, 3, \ldots\} \). The
cardinality of a set \( A \) will be denoted by \(|A|\) and we let \( \left( \begin{array}{c} [n] \\ 2 \end{array} \right) := \{S \subseteq [n] : |S| = 2\} \).
For any $n, m \in \mathbb{Z}$, we denote $n \equiv m$ if $n \equiv m \pmod{2}$. For $n \in \mathbb{P}$ we let,

$$[n]_{q} := \frac{1 - q^n}{1 - q}.$$  

It is immediate to see that $[1]_{q} = [1]_{-q}$ and that for $n \geq 2$

$$[n]_{q} = \begin{cases} 
[n]_{-q} + 2q + 2q^2 + \ldots + 2q^{n-1} & \text{if } n \text{ is even,} \\
[n]_{-q} + 2q + 2q^2 + \ldots + 2q^{n-2} & \text{if } n \text{ is odd.} 
\end{cases} \quad (2)$$

2.1 Symmetric group

Let $S_n$ be the set of all bijections $\sigma : [n] \to [n]$. If $\sigma \in S_n$ then we write $\sigma = \sigma_1 \ldots \sigma_n$ to mean that $\sigma(i) = \sigma_i$, for $i = 1, \ldots, n$. For $\sigma \in S_n$ and in general, for any sequence $\sigma = (\sigma_1, \ldots, \sigma_n) \in \mathbb{Z}^n$ we say that $(i, j) \in [n] \times [n]$ is an inversion of $\sigma$ if $i < j$ and $\sigma_i > \sigma_j$. We denote the number of inversions of $\sigma$ by $\text{inv}(\sigma)$. It is well known that $S_n$ is a Coxeter group respect to the generating set $S := \{s_i := (i, i+1) : i \in [n-1]\}$. The length of $\sigma \in S_n$, respect to $S$ is denoted by $\ell(\sigma)$. It is well known that $\ell(\sigma) = \text{inv}(\sigma)$ and the Poincaré polynomial of $W$ is given by

$$\sum_{\sigma \in S_n} q^{\ell(\sigma)} = [1]_{q}[2]_{q} \cdots [n]_{q}.$$  

We say that $i \in [n-1]$ is a descent of $\sigma = (\sigma_1, \ldots, \sigma_n) \in \mathbb{Z}^n$ if $\sigma_i > \sigma_{i+1}$. We denote by $\text{Des}(\sigma)$ the set of descents and by $\text{des}(\sigma)$ its cardinality. We also let

$$\text{maj}(\sigma) := \sum_{i \in \text{Des}(\sigma)} i \quad (3)$$

and call it the major index of $\sigma$.

The definition of Mahonian statistic, come from the following theorem due to MacMahon [15]. Foata gave a bijective proof of this result in [12].

**Theorem 2.1 (MacMahon)** Let $n \in \mathbb{P}$. Then

$$\sum_{\sigma \in S_n} q^{\text{maj}(\sigma)} = \sum_{\sigma \in S_n} q^{\ell(\sigma)}.$$  

For any element $w$ of a Coxeter group $W$, the sign of $w$ is defined to be

$$\text{sign}(w) := (-1)^{\ell(w)}.$$  

3
We prefer to use the notation \((-1)^{\ell(w)}\), instead of the usual sign(\(w\)), in order to avoid confusion between signed and even-signed permutations in the following Section 4. The following is a formula for the signed Mahonian for \(S_n\) and is due to Gessel and Simion [19].

**Theorem 2.2 (Gessel-Simion)** Let \(n \in \mathbb{P}\). Then

\[
\sum_{\sigma \in S_n} (-1)^{\ell(\sigma)} q^{\text{maj}(\sigma)} = [1]_q[2] - q \cdots [n]_q(-1)^{n-1}q.
\]

### 2.2 Hyperoctahedral group

We denote by \(B_n\) the group of all bijections \(\beta\) of the set \([-n, n] \setminus \{0\}\) onto itself such that

\[\beta(-i) = -\beta(i)\]

for all \(i \in [-n, n] \setminus \{0\}\), with composition as the group operation. This group is usually known as the group of signed permutations on \([n]\), or as the hyperoctahedral group of rank \(n\). If \(\beta \in B_n\) then we write \(\beta = [\beta_1, \ldots, \beta_n]\) to mean that \(\beta(i) = \beta_i\) for \(i = 1, \ldots, n\), we call this the window notation of \(\beta\). As set of generators for \(B_n\) we take \(S_B := \{s_{-1}^B, \ldots, s_{n-1}^B, s_0^B\}\), where for \(i \in [n-1]\)

\[s_i^B := [1, \ldots, i-1, i+1, i, i+2, \ldots, n]\]

and \(s_0^B := [-1, 2, \ldots, n]\).

It’s well known that \((B_n, S_B)\) is a Coxeter system of type \(B\) (see e.g., [7]). As for \(S_n\) we give an explicit combinatorial description of the length function \(\ell_B\) of \(B_n\) with respect to \(S_B\). For \(\beta \in B_n\) we let \(\text{Neg}(\beta) := \{i \in [n] : \beta_i < 0\}\),

\[N_1(\beta) := |\text{Neg}(\beta)|,
\]

and

\[N_2(\beta) := |\{\{i, j\} \in \binom{[n]}{2} : \beta_i + \beta_j < 0\}|.
\]

Note that, if \(\beta \in B_n\), then it’s not hard to see that

\[N_1(\beta) + N_2(\beta) = -\sum_{i \in \text{Neg}(\beta)} \beta(i).
\]

We have the following characterization of the length function (see e.g., [8]).
Proposition 2.3 Let $\beta \in B_n$. Then
\[ \ell_B(\beta) = \text{inv}(\beta) + N_1(\beta) + N_2(\beta). \]

The Poincaré polynomial of $B_n$ is
\[ \sum_{\beta \in B_n} q^{\ell_B(\beta)} = [2]_q[4]_q \cdots [2n]_q. \quad (5) \]

For any $\beta \in B_n$, the flag-major index of $\beta$, here denoted by $\text{fmaj}(\beta)$, is defined by
\[ \text{fmaj}(\beta) = 2 \text{maj}(\beta) + N_1(\beta), \quad (6) \]
where $\text{maj}$ is computed by using the following order on $\mathbb{Z}$
\[ -1 < -2 < \cdots < -n < \cdots < 0 < 1 < 2 < \cdots < n < \cdots \quad (7) \]
instead of the usual ordering, $\leq$.

For example, if $\beta = [2, -5, -3, -1, 4] \in B_5$, then $\text{Des}(\beta) = \{1, 2, 3\}$, hence $\text{maj}(\beta) = 6$ and $\text{fmaj}(\beta) = 15$. However be aware that $\text{inv}(\beta) = 3$.

The fmaj is a Mahonian statistic on $B_n$ (see [1, Theorem 2]).

Theorem 2.4 (Adin-Roichman) Let $n \in \mathbb{P}$. Then
\[ \sum_{\beta \in B_n} q^{\text{fmaj}(\beta)} = \sum_{\beta \in B_n} q^{\ell_B(\beta)}. \]

The following formula for the signed Mahonian polynomial of type $B$ has been recently discovered by Adin, Gessel, and Roichman [4].

Theorem 2.5 (Adin-Gessel-Roichman) Let $n \in \mathbb{P}$. Then
\[ \sum_{\beta \in B_n} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = [2]_{-1} q[2]_q \cdots [2n]_{(-1)^n} q. \]

The group $B_n$ has four one-dimensional characters. We have already shown formulas for the trivial and the sign character. The other two characters are $(-1)^{N_1(\beta)}$ and the sign of $(|\beta_1|, \ldots, |\beta_n|)$. Their generating functions can be easily obtained from (5) and Theorem 2.5, see [4].

Theorem 2.6 Let $n \in \mathbb{P}$. Then
\[ \sum_{\beta \in B_n} (-1)^{N_1(\beta)} q^{\text{fmaj}(\beta)} = [2]_{-1} q[2]_q \cdots [2n]_{(-1)^n-1} q; \]
\[ \sum_{\beta \in B_n} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = [2]_q[4]_q \cdots [2n]_{(-1)^n-1} q. \]
2.3 Even-signed permutation group

We denote by $D_n$ the subgroup of $B_n$ consisting of all the signed permutations having an even number of negative entries in their window notation, more precisely

$$D_n := \{ \gamma \in B_n : N_1(\gamma) \equiv 0 \}.$$ 

As a set of generators for $D_n$ we take $S_D := \{ s_0^D, s_1^D, \ldots, s_{n-1}^D \}$, where for $i \in [n-1]$

$$s_i^D := s_i^B \quad \text{and} \quad s_0^D := [-2, -1, 3, \ldots, n].$$

There is a well known direct combinatorial way to compute the length for $\gamma \in D_n$ (see, e.g., [7, §8.2]). Let $\gamma \in D_n$. Then

$$\ell_D(\gamma) = \text{inv}(\gamma) + N_2(\gamma).$$

Note that $\ell_D(\gamma) = \ell_B(\gamma) - N_1(\gamma)$. The Poincaré polynomial of $D_n$ is

$$\sum_{\gamma \in D_n} q^{\ell_D(\gamma)} = [2]_q[4]_q \cdots [2n-2]_q[n]_q.$$ 

For any $\gamma \in D_n$ let

$$|\gamma|_n := [\gamma(1), \ldots, \gamma(n-1), |\gamma(n)|].$$

Following [5], for $\gamma \in D_n$ we define the $D$-major index by

$$D\text{maj}(\gamma) := \text{fmaj}(|\gamma|_n).$$

We introduce the following subset of $B_n$,

$$\Delta_n := \{ \gamma \in B_n : \gamma(n) > 0 \}.$$ 

The map $\varphi : D_n \longrightarrow \Delta_n$ defined by $\gamma \mapsto |\gamma|_n$ is a bijection. So, by means of this bijection, any function defined on $\Delta_n$ can also be considered as a function defined on $D_n$. In what follows, we work with the subset $\Delta_n$ instead of $D_n$ in order to make some definitions and arguments more natural and transparent. In particular, for $\gamma \in \Delta_n$, we let

$$D\text{maj}(\gamma) := \text{fmaj}(\gamma). \quad (8)$$

For example if $\gamma = [2, -5, -3, -1, 4] \in \Delta_5$, then $\varphi(\gamma) = [2, -5, -3, -1, -4] \in D_5$ and $D\text{maj}(\gamma) = D\text{maj}(\varphi(\gamma)) = 15$.

The statistic $D\text{maj}$ is Mahonian on $D_n$ (see [5, Proposition 4.2]).
Theorem 2.7 (Biagioli-Caselli) Let \( n \in \mathbb{P} \). Then
\[
\sum_{\gamma \in \Delta_n} q^{D_{maj}(\gamma)} = \sum_{\gamma \in D_n} q^{\ell_B(\gamma)}.
\]

3 A sign-reversing involution on \( B_n \)

In this section we define a natural involution on \( B_n \) and derive some of its properties. In particular this allows an easy proof of the Adin-Gessel-Roichman formula for the signed-Mahonian for \( B_{2n} \). We will limit our discussion to the involution for \( B_{2n} \). The odd case is almost identical.

Let \( \iota : B_{2n} \to B_{2n} \) be the map defined by
\[
\beta \mapsto s_{2i-1} \cdot \beta,
\]
where \( i \in [n] \) is the smallest integer such that \( 2i-1 \) and \( 2i \) have opposite signs or are not in adjacent positions in the windows notation of \( \beta \). It no such \( i \) exists let \( \iota(\beta) := \beta \).

For example, \( \beta = [-3, -4, 1, 2, -6, -5] \) is a fixed point, and \( \gamma = [2, 6, 5, -4, -3, 1] \) is such that \( \iota(\gamma) = s_1 \gamma = [1, 6, 5, -4, -3, 2] \).

It is clear that when \( \beta \in B_{2n} \) is not a fixed point, the involution \( \iota \) reverses the sign of \( \beta \). However, it preserves the descent set \( \text{Des}(\beta) \), the number of negative entries \( N_1(\beta) \), and hence the flag-major index \( \text{fmaj}(\beta) \). Namely,
\[
\ell_B(\beta) \neq \ell_B(\iota(\beta)) \quad \text{and} \quad \text{fmaj}(\beta) = \text{fmaj}(\iota(\beta)).
\]

The following lemma will be fundamental in the proof of our main result.

Lemma 3.1 Let \( n \in \mathbb{P} \). Then
\[
\sum_{\substack{\beta \in B_{2n} \\ \text{fmaj}(\beta) = 1}} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = 0.
\]

Proof. From (10), all the terms in the RHS of (11) cancel except for the terms corresponding to the fixed points. Now let \( \beta \in B_{2n} \) such that \( \text{fmaj}(\beta) = 1 \). This implies that in the window notation of \( \beta \) there is an odd number of both negative and positive entries. Hence there exists at least one pair \( 2i-1, 2i \) in \( \beta \) with opposite signs. It follows that \( \beta \) is not a fixed point and this concludes the proof. \( \blacksquare \)
Now, let consider the set of fixed point of \( \iota \). Such elements in \( B_{2n} \) correspond bijectively to signed permutations in \( B_n \) with some entries “barred” according with the following rule:

- each pair of adjacent entries of type \( \pm(2i - 1), \pm 2i \) in \( \beta \) is replaced by \( \pm i \);
- each pair of adjacent entries of type \( \pm 2i, \pm(2i - 1) \) in \( \beta \) is replaced by \( \pm \bar{i} \).

We denote by \( B_n \) the set of all the barred signed permutations of \( [\pm n] \). Let \( \text{Des}(\bar{\beta}) \) and \( \text{maj}(\bar{\beta}) \) be defined without considering the bars and let \( S(\bar{\beta}) \) be the set of the positions of the barred entries.

For example, let \( \beta = [-3, -4, 1, 2, -6, -5] \in B_6 \) be a fixed point. Then \( \bar{\beta} = [-2, 1, -3] \in B_3 \) is the corresponding barred signed permutation, with \( \text{fmaj}(\bar{\beta}) = 5 \) and \( S(\bar{\beta}) = \{3\} \).

Since to compute the descent set we consider the reverse ordering (7) on the negative integers, it follows that

\[
\text{Des}(\beta) = \{2i : i \in \text{Des}(\bar{\beta})\} \cup \{2i - 1 : i \in S(\bar{\beta})\}.
\]

Hence

\[
\text{maj}(\beta) = 2 \text{maj}(\bar{\beta}) + \sum_{i \in S(\bar{\beta})} (2i - 1).
\] (12)

Differently, to compute the inversions of \( \beta \) we use the natural order \( \leq \). Hence

\[
\text{inv}(\beta) = 4 \text{inv}(\bar{\beta}) + |S(\bar{\beta})^+| + (N_1(\bar{\beta}) - |S(\bar{\beta})^-|)
\equiv N_1(\bar{\beta}) + |S(\bar{\beta})|,
\] (13)

where \( |S(\bar{\beta})^\pm| \) denote the number of positive and negative barred entries in \( \bar{\beta} \), respectively. Moreover, it is easy to see that

\[
N_1(\beta) + N_2(\beta) = - \sum_{i \in \text{Neg}(\bar{\beta})} (4\bar{i} + 1).
\] (14)

The following theorem holds.

**Theorem 3.2** Let \( n \in \mathbb{P} \). Then

\[
\sum_{\beta \in B_{2n}} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = \prod_{i=1}^{n} (1 - q^{4i-2}) \sum_{\beta \in B_n} q^{2\text{fmaj}(\beta)}.
\]
Proof. Since the involution $\iota$ is sign-reversing and $\text{fmaj}$ preserving, to compute the LHS is enough to perform the sum over the set of fixed points of $\iota$. So let $\beta \in B_{2n}$ a fixed point and $\bar{\beta}$ the corresponding barred signed permutation in $B_n$. From (12), (13), (14) and $N_1(\beta) = 2N_1(\bar{\beta})$, it follows

$$\text{fmaj}(\beta) = 4\text{maj}(\bar{\beta}) + \sum_{i \in S(\bar{\beta})} (4i - 2) + 2N_1(\bar{\beta})$$

and

$$\ell_B(\beta) \equiv N_1(\bar{\beta}) + |S(\bar{\beta})| + \sum_{i \in \text{Neg}(\bar{\beta})} (4\bar{\beta}_i + 1) \equiv |S(\bar{\beta})|.$$ 

Hence

$$\sum_{\beta \in B_{2n}} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = \sum_{\bar{\beta} \in B_n} (-1)^{|S(\bar{\beta})|} q^{\sum_{i \in S(\bar{\beta})}(4i - 2)} q^{2\text{fmaj}(\bar{\beta})}$$

$$= \prod_{i=1}^{n} (1 - q^{4i - 2}) \sum_{\beta \in B_n} q^{2\text{fmaj}(\beta)}.$$

The case even of Theorem 2.5 follows directly by this and (5).

Corollary 3.3 Let $n \in \mathbb{P}$. Then

$$\sum_{\beta \in B_{2n}} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = [2]_q [4]_q \cdots [4n]_q.$$ 

In the case of $B_{2n+1}$, the fixed points of the involution $\iota$ are the signed permutations such that, for every $i \in [n]$ the entries $2i - 1$, $2i$ have same sign and are in adjacent positions in the window notation of $\beta$. This forces the entry $\pm(2n + 1)$ to be in an odd-position. It is possible to obtain the Adin-Gessel-Roichman formula also in this case, again by summing over the set of fixed points just described. Since this procedure it is very technical and not easier than the original proof it is not worth presenting here.

4 A Signed Mahonian for $D_n$

In this section we provide a factorial-type formula for the signed Mahonian polynomial for the Weyl group $D_n$. 

9
For any $\beta = [\beta_1, \ldots, \beta_n]$ let $-\beta := [-\beta_1, \ldots, -\beta_n]$. It is easy to see that the following equalities hold:

$$\text{inv}(-\beta) = \binom{n}{2} - \text{inv}(\beta), \ N_1(-\beta) = n - N_1(\beta), \ \text{and} \ N_2(-\beta) = \binom{n}{2} - N_2(\beta).$$

It follows

$$\ell_B(-\beta) \equiv \ell_B(\beta) + n. \quad (15)$$

A proof of the following lemma can be found in [5, Corollary 3.13].

**Lemma 4.1** Let $\gamma \in \Delta_n$. Then

$$\text{fmaj}(-\gamma) = \text{fmaj}(\gamma) + n.$$

**Proposition 4.2** Let $n \in \mathbb{P}$. Then

$$\sum_{\beta \in B_n} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = \sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{Dmaj}(\gamma)} (1 + (-q)^n).$$

**Proof.** From Lemma 4.1, (15) and (8) we have

$$\sum_{\beta \in B_n} (-1)^{\ell_B(\beta)} q^{\text{fmaj}(\beta)} = \sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{fmaj}(\gamma)} + (-1)^{\ell_B(-\gamma)} q^{\text{fmaj}(-\gamma)}$$

$$= \sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{fmaj}(\gamma)} + (-1)^{\ell_B(\gamma)+n} q^{\text{fmaj}(\gamma)+n}$$

$$= \sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{fmaj}(\gamma)} (1 + (-q)^n)$$

$$= \sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{Dmaj}(\gamma)} (1 + (-q)^n).$$

The following are immediate consequences of Theorem 2.5.

**Corollary 4.3** Let $n \in \mathbb{P}$ be even. Then

$$\sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{Dmaj}(\gamma)} = [2]_{-q}[4]_{-q} \cdots [2n]_{-q}[n]_{-q}.$$

**Corollary 4.4** Let $n \in \mathbb{P}$ be odd. Then

$$\sum_{\gamma \in \Delta_n} (-1)^{\ell_B(\gamma)} q^{\text{Dmaj}(\gamma)} = [2]_{-q}[4]_{-q} \cdots [2n-2]_{-q}[n]_{-q}.$$
We denote by $\Delta^0_n$ and $\Delta^1_n$ the subsets of all $\gamma \in \Delta_n$ such that $D_{maj}(\gamma) \equiv 0$ and $D_{maj}(\gamma) \equiv 1$, respectively. The subsets $D^0_n$ and $D^1_n$ are defined in a similar way.

**Lemma 4.5** Let $n \in \mathbb{P}$. Then

$$\sum_{\gamma \in \Delta^0_n} (-1)^{\ell_B(\gamma)} q^{D_{maj}(\gamma)} = \sum_{\gamma \in D^0_n} (-1)^{\ell_D(\gamma)} q^{D_{maj}(\gamma)}.$$  

**Proof.** Every signed permutation $\gamma \in \Delta^0_n$ is such that $N^1(\gamma) \equiv 0$. Hence $\gamma \in D^0_n$ and $\ell_B(\gamma) = inv(\gamma) + N^1(\gamma) + N^2(\gamma) \equiv inv(\gamma) + N^2(\gamma) = \ell(\gamma).$

**Lemma 4.6** Let $n \in \mathbb{P}$. Then

$$\sum_{\beta \in \Delta^1_n} (-1)^{\ell_B(\beta)} q^{D_{maj}(\beta)} = -\sum_{\gamma \in D^1_n} (-1)^{\ell_D(\gamma)} q^{D_{maj}(\gamma)}.$$  

(16)

**Proof.** Let $\beta := [\beta_1, \ldots, \beta_{n-1}, k] \in \Delta^1_n$. This implies $N^1(\beta) \equiv 1$ and so $\beta \in B_n \setminus D_n$. Let $\gamma := \varphi^{-1}(\beta)$, i.e., $\gamma := [\beta_1, \ldots, \beta_{n-1}, -k] \in D^1_n$. We have

$$N^2(\gamma) = N^2(\beta) + (k - 1) \text{ and } inv(\gamma) = inv(\beta) + (k - 1).$$

It follows that

$$\ell_B(\beta) = inv(\beta) + N^1(\beta) + N^2(\beta) \not\equiv inv(\beta) + 2(k - 1) + N^2(\beta) = \ell_D(\gamma).$$

**Lemma 4.7** Let $n \in \mathbb{P}$ even. Then

$$\sum_{\beta \in \Delta^1_n} (-1)^{\ell_B(\beta)} q^{D_{maj}(\beta)} = 0.$$  

(17)

**Proof.** Let consider the restriction of the involution $\iota : B_n \rightarrow B_n$ defined in (9) to $\Delta^1_n$. It is easy to see that none of the elements of $\Delta^1_n$ is a fixed point for $\iota$, and that $D_{maj}(\beta) = D_{maj}(\iota(\beta))$. Hence all the terms in the RHS of (17) cancel and the result follows.

Now, we are ready to show the main result of this section.
Theorem 4.8 (Signed Mahonian of type $D$) Let $n \in \mathbb{P}$. Then
\[
\sum_{\gamma \in D_n} (-1)^{\ell_D(\gamma)} q^{D_{\text{maj}}(\gamma)} = \begin{cases} 
[2]_q - q[4]_q \cdots [2n - 2]_q [n]_q & \text{if } n \text{ is even,} \\
[2]_q - q[4]_q \cdots [2n - 2]_q [n]_q & \text{if } n \text{ is odd.}
\end{cases}
\]

Proof. If $n$ is even, from Lemmas 4.5 and 4.6, and Lemma 4.7, it follows
\[
\sum_{\gamma \in D_n} (-1)^{\ell_D(\gamma)} q^{D_{\text{maj}}(\gamma)} = \sum_{\beta \in \Delta_n} (-1)^{\ell_B(\beta)} q^{D_{\text{maj}}(\beta)} = \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot [n]_{-q}.
\]
Hence the result follows by Corollary 4.3.

If $n$ is odd, from Corollary 4.4, we have
\[
\sum_{\beta \in \Delta_n} (-1)^{\ell_B(\beta)} q^{D_{\text{maj}}(\beta)} = [2]_q - q[4]_q \cdots [2n - 2]_q [n]_{-q}.
\]
By Theorem 2.5, this implies
\[
\sum_{\beta \in \Delta_n} (-1)^{\ell_B(\beta)} q^{D_{\text{maj}}(\beta)} = \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot (-q - q^3 - \ldots - q^{n-2}).
\]
By Corollary 3.1, the first factor in the RHS of (18) has only even powers, hence
\[
\sum_{\beta \in \Delta_n} (-1)^{\ell_B(\beta)} q^{D_{\text{maj}}(\beta)} = \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot (-q - q^3 - \ldots - q^{n-2}).
\]
Again from Lemmas 4.5 and 4.6 and (18), it follows
\[
\sum_{\gamma \in D_n} (-1)^{\ell_D(\gamma)} q^{D_{\text{maj}}(\gamma)} = \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot [n]_{-q} - 2 \sum_{\beta \in \Delta_n} (-1)^{\ell_B(\beta)} q^{D_{\text{maj}}(\beta)}
\]
Now by (19), (2) and Theorem 2.5 the RHS is equal to
\[
= \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot ([n]_{-q} + 2(q + q^3 + \ldots + q^{n-2}))
\]
\[
= \sum_{\beta \in B_{n-1}} (-1)^{\ell_B(\beta)} q^{f_{\text{maj}}(\beta)} \cdot [n]_q
= [2]_q - q[4]_q \cdots [2n - 2]_q [n]_q.
\]
\[\blacksquare\]
