Abstract- The problem of parameter estimation of rough surface contact interaction due to 3D modelling of fractal model contact interaction, when they are satisfactory to initial surfaces, is solved. This approach takes into account surface contour basic parameters that are essentially relevant to the results and accuracy of the calculation.

Keywords- modeling, contact stiffness, contact interaction, fractal surface, surface contingency, contact patches.

I. INTRODUCTION

Machine part surfaces have a number of properties that characterize their quality. These include topography (macro-deciles, surface undulation and surface contour), physical, mechanical and chemical features of the surface coating and afterstrains in the near-surface zones. The contact between two rough surfaces consists of a microcontact set reacting the load and specifying the actual contact area of physical bodies mating. Actual contact area is usually significantly less than the nominal (geometric) contact area, and it is the actual area that determines these important mating parameters: contact stiffness, electrical and thermal conductivity, etc. Therefore, from the point of view of abut operating condition ensuring, it is especially important to specify the contact interaction parameters.

To describe the quality of behavior of surface contour contact in some cases statistical models, the parameters of which depend on the scale [1, 2] are used. The model of surface contour with the parameters being invariant to the scale is presented in works [3, 4]. These works are based on fractal properties; the surface contour (profile) model is described by the Weierstrass - Mandelbrot equation. Majumdar – Bhushan (M-B) model considering the elastoplastic contact, suggests that in the process of contact load increase there should be a plastic contact, which with a further growth in the load, changes into an elastic state and it contradicts the classical approach of Hertz theory.

The authors of the M-B model believe that small inequalities covering the protrusion are deformed plastically and in the process of coalesce with each other form a larger contact patch being in an elastic state. If the protrusion in the M-B model is thought of as a smooth spherical segment in its upper part then the use of Hertz theory for a specific protrusion and transition condition from the elastic state to the elastoplastic is appropriate.
In this case, the rough surface model is represented as a set of spherical segments located on the middle plane and having statistically distributed heights. Provided that the radii of the protrusion upper parts are of equivalent grade the rough surface is described within the Greenwood-Williamson model.

In actuality the problems of friction and wear take into consideration the protrusion upper part deformation, for which the radius of curvature will be different in contrast to the model M-B (Fig. 2).

Imagine a protrusion in the form of a cone and we’ll have:

$$\frac{4\pi r'^2}{\pi l^2} = \frac{\omega}{\delta}. \tag{2}$$

After deformation of the upper part of the protrusion, the actual contact area \(a\) at the elastic state of the contact is equal to:

$$\pi r'^2 = 2a. \tag{3}$$

Fig. 2. Model of protrusion

Inserting the expression (3) into equation (2), we will have:

$$\frac{8a}{\pi l^2} = \frac{\omega}{\delta}. \tag{4}$$

At the same time \(\omega \equiv r' \left(\text{tg}\theta\right)\); \(\delta = (l/2) \text{tg}\theta\). Further:

$$\frac{\omega}{\delta} = \frac{2r'}{l} = \frac{8a}{l^2}$$

or:

$$\frac{4a}{\pi l} = r'. \tag{5}$$

We’ll change the equation (4) as follows:

$$\left(\frac{4a}{\pi l}\right)^2 = r'^2 \frac{\pi}{\pi}.$$

From which:

$$l = \left(\frac{8a}{\pi}\right)^{1/2}. \tag{6}$$

Inserting the expression (5) into equation (1), we’ll have:

$$R = \frac{(8a)^{(2D-1)/2}}{4\pi^{(3+D)/2}G^{(D-2)}(\ln\gamma)^2}. \tag{7}$$

III. THE MODEL OF CONTACT INTERACTION

Unlike the M-B model, the protrusion shown in Fig. 2 and having a certain radius of curvature in the upper part, it is
deformed first elastically, and then with an increase in the load it is distorted plastically. The Majumdar – Bhushan (M-B) model assumes that contact patches, having an area that is greater than some critical value of \( a_0 \), are in an elastic state from the beginning of deformation \( \delta \). Contact patches with an area of \( a < a_0 \) are plastically distorted by deformation \( \delta > \delta_c \).

In the process of spreading, they approach each other and it results in both: a growth of contact patches and a transition from plastic to elastic contact. Majumdar and Bhushan believe that “due to the fact that smaller contact patches have smaller curve radius, so they will more likely undergo plastic deformation”. This result contradicts classical contact mechanics, that is either Hertz theory or the Greenwood – Williamson model (G-W). The reason for this discrepancy lies in the assumption, that patch area \( a \leq \frac{1}{2} \) and \( \omega = \delta \) in the model M-B [5].

Protrusion model (Fig. 2) implies the presence of a smooth spherical segment at the top in deformation of unevenness being \( 0 \leq \omega \leq \delta \). Radius of the upper part of the protrusion \( R \) differs from either M-B or G-W models. We believe that, unlike M-B model, the elastic contact fulfills the condition \( \omega < \omega_c \) and \( a > a_0 \), while the plastic contact obeys the condition of \( \omega > \omega_c \) and \( a > a_0 \), and that in agreement with classical mechanical principles of contact interaction. With an increase in the load on the flat die we have the following stages of the protrusion deformation: elastic, elastoplastic - 1, elastic-plastic - 2 and plastic. We believe that in order to simplify the problem there are only two types of the state: elastic and plastic.

The relation between the load and the contact patch area is as follows:

- for elastic contact

\[
F^0_e = \frac{4}{3} ER^2a^2 = \frac{4}{3} ER^2 \left( \frac{a}{nR} \right)^2 = \frac{4Ea^2}{3\pi^2R} \left( \frac{1}{E} \right)
\]

\[
= \left[ 1 - \frac{\mu_1^2}{E_1} + \frac{1 - \mu_2^2}{E_2} \right]
\]

- for plastic contact

\[
F_p = Ha; \quad H = \min\{H_1, H_2\}.
\]

Here: \( E_1, E_2, \mu_1, \mu_2 \) are elastic moduli, Poisson’s ratios of physical agents’ tying-in; \( H \) – hardness.

Inserting the radius expressed by the equation (6) into the ratio for the elastic contact, we have:

\[
F^0_e = \frac{2(11-3D_S)/2}{3} E\pi(0.5/2)G(0.5-2)(\ln\gamma)^{1/2}a^{(4-D_S)/2}
\]

\[
= Q \ a^{(4-D_S)/2}.
\]

Here:

\[
Q = \frac{2(11-3D_S)/2}{3} E\pi(0.5/2)G(0.5-2)(\ln\gamma)^{1/2}.
\]

The transition criterion is determined on the basis of equality \( F_e = F_p \). Setting equal load of both elastic and plastic states, we will have the following expression after the transformation of the critical value of the contact patch area:

\[
a_e = \frac{9}{256\pi} \left( \frac{H}{E} \right)^2 \frac{G^{(D_S-1)}}{C^{(2(D_S-2))\ln(\gamma)}}^{1/(2-D_S)}
\]

**Multiple contact.** Figure 3 shows milling and abrasive surface matching (top) and two abrasive surfaces (bottom), as well as contact areas mating them. The actual contact area is the product of the number of actual spots and the average contact patch area:

\[
A_r = N(a > a_{min})a.
\]

![Fig. 3. Rough surfaces matching and their contact patches: milling and abrasive (above), and two abrasive (below)](image-url)

The number of spots being greater than the minimum value is estimated by [3]

\[
N(a > a_{min}) = \left( \frac{a_{max}}{a_{min}} \right)^{(D_S-1)/2} = \left( \frac{a_{max}}{a_{min}} \right)^D, \quad D = D_S - 1.
\]

We shall find the average area of the contact patches, denoting a dimensionless area expressed in terms of \( \alpha = \frac{a}{a_{max}} \):

\[
\langle a \rangle = a_{max} \int_0^1 f(a^*)a^* \, da^*.
\]

Taking the differential distribution function of the relative contact areas [6] as:

\[
f(a^*) = (1 - a^*)a^{(-\alpha)}
\]

inserting it in equation (7), we shall write:

\[
\langle a \rangle = a_{max} \frac{1 - \alpha}{2 - \alpha}.
\]

The exponent \( \alpha \) is defined as follows. We simulate mating fractal surfaces (Fig. 1) and the get contact patch. We find the areas of contact patches and construct an empirical distribution function, the approximation of which is written as:
Advances in Engineering Research, volume 188

The dependence of the area \( a' \), size of the area \( f_{\text{a}} \), the relative area (bearing area) is determined by the expression:

\[
F(a') = a'^{(1-a)}.
\]

Finally, we shall write the expression for the actual contact area:

\[
A_r = \frac{(a+D/2)}{a_{\text{max}}} \frac{1-a}{a_{\text{min}}}.
\]

The elastic and plastic parts of the actual contact area are measured by the following functional connections:

\[
A_{re} = \frac{(a+D/2)}{a_{\text{max}}} \frac{1-a}{a_{\text{min}}} (a')^{2-a},
\]

\[
A_{rp} = \frac{(a+D/2)}{a_{\text{max}}} \frac{1-a}{a_{\text{min}}} [1 - (a')^{2-a}].
\]

Now: \( a'_c = a_c/a_{\text{max}} \).

IV. THE RESULT OF COMPUTER SIMULATION OF CONTACT INTERACTION OF SURFACES

The functional connection \( F_e (a') \) is determined by the expression:

\[
F_e = \left( \frac{a_{\text{max}}}{a_{\text{min}}} \right) \int_0^1 a' (3-D) a (1-a) a'^{(2-a)} da'.
\]

\[
= \frac{a_{\text{max}}}{a_{\text{min}}} \int_0^1 2(1-a) (5-D) a^{(5-D-2a)/2} \quad \text{for} \quad 0 \leq a' \leq a_c.
\]

Functional connection \( F_e (a') \) presented in fig. 4 is deduced in the following way: \( R_e = 1.2 \) mm; \( G = 6 \cdot 10^6 \) mm; \( D = 1.5; \ D_0 = 2.5; \) \( f_{\text{a}} = 0.5; \) \( Q = 731.42 \) mm; \( E = 10^5 \) MPa; \( H = 2000 \) MPa; \( a_{\text{max}} = a_c = 5.769 \cdot 10^4 \) mm; \( a_{\text{min}} = 10^{-3} \) mm; \( a' = a/a_c \).

Plastic contact takes place at \( a \geq a_c \). The expression for the patches in the plastic state we use in the form:

\[
F_p = \left( \frac{a_{\text{max}}}{a_{\text{min}}} \right) H \int_{a_c}^{a'} a' a_{\text{max}}(1-a) a'^{(2-a)} da' =
\]

\[
= \frac{(a+D/2)}{a_{\text{max}}} \frac{1-a}{a_{\text{min}}} [a^{(2-a)} - a_c^{(2-a)}], \quad a'_c \leq a' \leq 1.
\]

Besides using previously taken initial data we shall assume \( a_{\text{max}} = [50;75;100] \) \( a_c \), we shall find: \( a_{\text{max}} = [50;7.569 \cdot 10^4; 75;7.569 \cdot 10^4; 100;57.69 \cdot 10^4].

The dimensionless critical area of the patch will be equal to:

\[
a'_c = 1/50; 1/75 \text{ and } 1/100.
\]

Evaluation of the nominal area. The dependence of the relative area (bearing area) \( Ar/Aa \) on the contingency is determined by the expression:

\[
\frac{Ar}{Aa} = 0.5 \text{erfc} \left( \sqrt{2R_q} \right).
\]

where: \( Ar \) - the actual contact area; \( Aa \) - nominal (geometric) area; \( \text{erfc}(\text{...}) \) - error function; \( Y \) - the distance between the average quadratic deviation of outline ordinates and a flat die; \( R_q \) - average quadratic deviation of rough surface.

As the distance \( Y \) is reduced (while convergence increases), the bearing area grows. At \( Y = 0 \) the function \( \text{erfc}(0) = 1 \) and \( Ar = 2A_r \), the Actual area, consisting of individual patches is determined by the expression quoted above:

\[
A_r = \frac{a_{\text{max}}}{a_{\text{min}}} \frac{(1-a)}{a_{\text{min}}}, \quad 1 < D < 2.
\]

The maximum area of the contact patch in accordance with Fig. 2 when \( z(x) = 0 \) is equal to:

\[
a_{\text{max}} = \pi (R_p t g \theta)^2.
\]

Here: \( R_p \) is the smoothing height; \( t g \theta = \Delta q \) is the slope of the unevenness with towards the midline.

At the same time:

\[
a_{\text{max}} = \pi (S_m)^2/4,
\]

where \( S_m \) - is statistical estimate of roughness width along the midline.

Fig. 5 shows special intersection points (zeros) of the section-gage log with the midline. The roughness width along the midline is defined directly by the number of zeros \( n (0) \) designated as the selected length of the profile line:

\[
S_m = \frac{2}{n(0)}.
\]
The average values of number of zeros (mm⁻¹) fitting in any given processing type (tbl. 1) are provided below [7].

![Image](image-url)

**TABLE I. THE AVERAGE VALUES OF THE NUMBER OF ZEROS AND THE AVERAGE PITCH**

| Type of processing | $R_m$, µm | $R_s$, µm | $R_{max}$, µm | $n(0)$, mm⁻¹ | $S_m$, µm |
|--------------------|-----------|-----------|---------------|--------------|-----------|
| Flat grinding      | 3.25      | 2.51      | 11.19         | 15           | 133.32    |
|                    | 1.70      | 1.37      | 4.25          | 27           | 74.08     |
|                    | 1.19      | 0.89      | 2.42          | 34           | 58.82     |
|                    | 0.73      | 0.56      | 1.66          | 51           | 39.22     |
| Circular grinding  | 0.29      | 0.23      | 0.79          | 140          | 14.28     |
| Reseat (fitting)   | 0.14      | 0.11      | 0.34          | 163          | 12.26     |

Functional connections (according to J. A. Rudzit) for the average pitch have the form:

$$S_m = \begin{cases} 
\frac{2}{200-278R_a} & R_a \leq 0.63, \ \mu m; \\
\frac{2}{43-11R_a} & R_a > 0.63 \ \mu m. 
\end{cases}$$

Taking up $a_{min} = 10^{-3}a_{max}$; $\alpha = 0.5$; $D = 1.5$ we obtain the following ratio making possible to tie together both: relative area and type of processing (tbl. 2):

$$\frac{A_r}{A_a} = 10^{3D/2} a_{max}^2.$$  

**TABLE II. THE NOMINAL CONTACT AREA FOR THE FRACTAL MODEL**

| Type of processing | $R_s$, µm | $S_s$, µm | $a_{max}$, mm² | $A_a$, mm² |
|--------------------|-----------|-----------|---------------|-----------|
| Flat grinding      | 2.51      | 133.32    | 3.49·10⁻³     | 0.414     |
|                    | 1.37      | 74.08     | 1.07·10⁻³     | 0.126     |
|                    | 0.89      | 58.82     | 6.79·10⁻⁴     | 0.080     |
|                    | 0.56      | 39.22     | 3.13·10⁻⁴     | 0.040     |

Fig. 6 presents a dependency graph showing how relative area depends on maximum contact patch area (for the surface with $R_s = 1.37 \ \mu m $ $\alpha = 0.5$)

![Image](image-url)

**Fig. 6. The dependence of the relative area on the maximum area of the contact patch under different fractal dimension conditions**

Making the census of this expression as:

$$F_e = \frac{a_{max}^{3/2}}{a_{min}^{D/2}} Q \left(\frac{2(1 - \alpha)}{(5 - D - 2\alpha)}\right)^{a^{(5-D-2\alpha)/2}}, \quad 0 \leq a^* \leq a_c = 1,$$

where $a^* = a/a_{max}$.

Taking the contact stiffness equal to:

$$K_N = \frac{dF_e}{d\omega}$$

Factoring the relationship between the area of the contact patch $a$ and deformation $\omega$ that is written as:

$$a = \pi R_0 \omega.$$

Inserting the value of the radius of the fractal protrusion and modifying the deduced expression with respect to the area of the contact patch, we obtain:

$$a = \frac{2^{3D_5-7}}{\left[\pi^{D_5+1} G^{2D_5-2}(\ln\gamma)^{1/3-D_5}\right]^{1/(3-D_5)}} \omega^{2/(3-D_5)},$$

where $D_5 = 2.5$ we have:

$$a = \frac{\sqrt{2}}{\left[\pi^{3.5} G (\ln\gamma)^{1/3}\right]^2} \omega^4.$$

Inserting the expression (10) into the equation (9) and making the following development of it taking into account that $D_5=D+1$, we obtain:

$$F_e = \frac{a_{max}^{3(5-D-2\alpha)/2}}{a_{min}^{D/2}} Q \left(\frac{2(1 - \alpha)}{(5 - D - 2\alpha)}\right)^{a^{(5-D-2\alpha)/2}},$$

where

$$\left\{\begin{aligned}
&2^{3D_5-7}\omega^{2/(3-D_5)} \\
&\left[\pi^{3.5} G^{2D_5-2}(\ln\gamma)^{1/3-D_5}\right]^{1/(3-D_5)}
\end{aligned}\right\}^{(5-D-2\alpha)/2}$$
where $D = 1.5$ ($D_0 = 2.5$) we get

$$F_e = \frac{a_{c_{0.25}}}{a_{c_{0.75}}} Q \cdot 0.4 \left( \frac{\sqrt{2} \omega^4}{[\pi D^5 + 1G(hy)^2]} \right)^{1.25}.$$ 

We obtain best possible:

$$F_e = Q^* \omega^5.$$  \hspace{1cm} (11)

At this time:

$$Q^* = 2.632 \cdot 10^{-4} \frac{a_{c_{0.25}}}{a_{c_{0.75}}} Q \frac{G}{G^2}.$$  

The normal contact stiffness is:

$$K_N = 5Q^* \omega^4.$$  

As an illustration and putting the results obtained earlier by other researchers into perspective we give a numerical example. Let us take the following initial data: $R_a = 2.95 \mu m$; $a = 0.5$; $D = 1.5$. For grinding finish we estimate the fractal roughness parameter approximately:

$$G = 10^{-5.26/R_a^{0.042}} = 10^{- \frac{5.26}{2.65 \mu m}} = 9.411 \cdot 10^{-6} mm.$$  

Let’s define other parameters:

- the maximum area of elastic contact (according to the formula 10 when hardness of $H = 2000$ MPa and $E = 10^8$ MPa) - $a_{c_{0.25}} = 1.419 \cdot 10^{-3} mm^2$;
- $Q = 916,037$ (H/mm)mm$^{0.5}$;
- $Q^* = 4.219 \cdot 10^{15} \left( \frac{H}{mm^5} \right)$.

Then the contact stiffness is determined by the dependence:

$$K_N = 21.095 \cdot 10^{15} \omega^4.$$  

Fig. 7 presents a dependency graph showing how contact stiffness depends upon approaching.

Using the expression (11), we find the following dependence of the load upon the approaching for the elastic contact when the following initial data:

$D_0 = 1.585$; $G = 10^{-9}$mm; $a_{c_{0.25}} = 6.956 \cdot 10^{-12}$ mm$^2$.

$$F_e = 5.59 \cdot 10^{19} \omega^{5.019}.$$  

The relationship between approaching and load is:

$$\omega = 0.4045 F_e^{0.172}.$$  

Fig. 8 presents the dependences of the approaching upon the load. Comparison of these dependencies is made considering sufficiently similar values of the topographic parameters of the flat joint steel face.

V. CONCLUSION

Thus, the proposed fractal model of contact interaction of the flat joint takes into account those parameters of rough surfaces, which have a significant importance for the result and accuracy of the calculation. These parameters include fractal dimension $D$ and fractal roughness $G$, which are associated with the roughness parameters according to GOST 2789-73.
