Regularity and time behavior of the solutions to weak monotone parabolic equations

MARIA MICHELA PORZIO

Abstract. In this paper, we study the behavior in time of the solutions for a class of parabolic problems including the $p$-Laplacian equation and the heat equation. Either the case of singular or degenerate equations is considered. The initial datum $u_0$ is a summable function and a reaction term $f$ is present in the problem. We prove that, despite the lack of regularity of $u_0$, immediate regularization of the solutions appears for data $f$ sufficiently regular and we derive estimates that for zero data $f$ become the known decay estimates for these kinds of problems. Besides, even if $f$ is not regular, we show that it is possible to describe the behavior in time of a suitable class of solutions. Finally, we establish some uniqueness results for the solutions of these evolution problems.

1. Introduction

Let us consider the following nonlinear parabolic problem

\[
\begin{aligned}
&u_t - \text{div}(a(x, t, u, \nabla u)) + \alpha_0 u = f(x, t) \quad \text{in} \quad \Omega_T, \\
&u = 0 \quad \text{on} \quad \Gamma, \\
&u(x, 0) = u_0(x) \quad \text{on} \quad \Omega,
\end{aligned}
\]

where $\Omega_T = \Omega \times (0, T)$, $\Omega$ is an open bounded set of $\mathbb{R}^N$, $N \geq 2$, $T > 0$, $\alpha_0 \geq 0$ and $\Gamma = \partial\Omega \times (0, T)$, with $\partial\Omega$ regular (for example, satisfying the property of positive geometric density\(^1\)).

Here, the function $a(x, t, s, \xi) : \Omega \times (0, T) \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ is a Caratheodory function\(^2\) satisfying, for a.e. $(x, t) \in \Omega_T$ and for every $s \in \mathbb{R}$, $\xi$ and $\eta \in \mathbb{R}^N$ the

**Keywords:** Decay estimates, Asymptotic behavior, Regularity of solutions, Nonlinear parabolic equations, Uniqueness results.

\(^1\) We say that $\Omega$ satisfies the property of positive geometric density if there exists $\alpha^* \in (0, 1)$ and $\rho_0 > 0$ such that for every $x_0 \in \partial\Omega$ and for every ball $B_\rho(x_0)$ centered at $x_0$ and radius $\rho \leq \rho_0$ it results

\[|\Omega \cap B_\rho(x_0)| \leq (1 - \alpha^*)|B_\rho(x_0)|.\]

\(^2\) That is, it is continuous with respect to $(s, \xi)$ for almost every $(x, t) \in \Omega_T$, and measurable with respect to $(x, t)$ for every $(s, \xi) \in \mathbb{R} \times \mathbb{R}^N$. 
following structure conditions

\[
\alpha |\xi|^p \leq a(x, t, s, \xi) \leq \beta (|s|^{p-1} + |\xi|^{p-1} + h(x, t)), \quad \beta > 0,
\]

where

\[
h^{p'} \in L^s(0, T; L^q(\Omega)), \quad \frac{1}{s} + \frac{N}{pq} < 1, \quad \frac{1}{p} + \frac{1}{p'} = 1.
\]

Finally, on the initial datum \( u_0 \) we assume

\[
u_0 \in L^{r_0}(\Omega), \quad r_0 \geq 1,
\]

while on \( f \) we require

\[
f \in L^\infty(\Omega_T),
\]

or simply that

\[
f \in L^1(\Omega_T).
\]

Aim of this paper is to study the behavior of the solutions of (1.1).

This evolution problem includes, as particular cases, the heat equation and the \( p \)-Laplacian equation, and has been widely studied starting from the sixties by the classical papers of Nash, Moser, Ladyženskaja, Solonnikov, Ural’ceva, J.L. Lions, Aronson, Serrin, Trudinger (see [2,33,34,36,37,53] and the references therein) to nowadays and it is really a difficult task to give a complete bibliography on this subject (see for example [1,3,4,6–8,10–12,17,19–26,29–32,35,39–41,45,45,51,52,54,56,57] and the references therein).

Nevertheless, we show in this paper some unknown surprising properties of the solutions.

The first issue we want to address stems from the following unexpected and incredible result:

even if the initial datum \( u_0 \) is only a summable function, if the reaction term \( f \) is the zero function and \( p \) is “not too small” (i.e., \( p > \frac{2N}{N+r_0} \)), then there exists a solution \( u \) of (1.1) which “immediately” becomes bounded, i.e., such that

\[
u(t) \in L^\infty(\Omega), \quad \text{for every } t \in (0, T).
\]

Moreover, it is also possible to estimate the \( L^\infty \)-norm of \( u(t) \) but these estimates differ with \( p \) and exhibit a different behavior in the degenerate case from the singular one. In particular, in the degenerate case \( p > 2 \) the following decay estimate holds true

\[
\|u(t)\|_{L^\infty(\Omega)} \leq \frac{C}{t^{\frac{p-2}{2}}} \quad \text{for every } t \in (0, T),
\]
where $C$ is a constant depending only on $\alpha, N, |\Omega|$ and $p$ (see [14,42] and the references therein) and hence is an estimate that doesn’t depend on the initial datum $u_0$ and for this reason it is also called universal (decay) estimate.

We point out that the universal estimate (1.9) is a peculiarity of the degenerate case (in a bounded domain) and it is no longer true in the singular case $p < 2$ or for $p = 2$.

If $p = 2$, the same decay of the heat equation appears since the following exponential estimate holds true

$$
\|u(t)\|_{L^\infty(\Omega)} \leq C \frac{\|u_0\|_{L^{r_0}(\Omega)}}{t^{\frac{N}{r_0}}} e^{\sigma t}
$$

for every $t \in (0, T)$, where $\sigma$ is a positive constant depending only on $\alpha, N, r_0$ and $\Omega$.

Finally, if $p > \frac{2N}{N + r_0}$, hence in both the previous cases and in the singular case too with $p$ “not too small,” the following estimate holds true

$$
\|u(t)\|_{L^\infty(\Omega)} \leq C \frac{\|u_0\|_{L^{h_0}(\Omega)}}{t^{h_1}}
$$

for every $t \in (0, T), \quad (1.10)$

where $C$ depends only on $\alpha, p$ and $N$ and

$$
h_0 = \frac{pr_0}{N(p - 2) + pr_0}, \quad h_1 = \frac{N}{N(p - 2) + pr_0},
$$

(see [28,42,54,55] and the references therein).

The previous estimates, known in the literature as decay or ultracontractive estimates or smoothing effects (see [54]), describe the behavior in time of the solutions and are of interest not only for $t$ large, since they describe in which way $u$ decays to zero letting $t \to +\infty$, but also for $t$ near zero, since they describe the “controlled blow-up” of the $L^\infty$-norm of $u(t)$ for $t$ that goes to zero.

The first aim of this paper is to understand what happens when the reaction term $f$ is not the zero function. In other words, we want to understand if for suitably regular data $f$ (otherwise the result is false) it is still true that even in the presence of an only summable initial datum $u_0$ there exists a solution of (1.1) which becomes “instantaneously bounded” and, in case of an affirmative answer, which kind of estimates we can expect.

The author has already studied this problem in the nonsingular case $p \geq 2$ when the operator $a$ is independent of $u$ (i.e., $a(x, t, s, \xi) = a(x, t, \xi)$) and satisfies the following monotony assumption

$$
[a(x, t, \xi) - a(x, t, \eta)](\xi - \eta) \geq \gamma |\xi - \eta|^p,
$$

for a.e. $(x, t) \in \Omega_T$ and for every $\xi, \eta \in \mathbb{R}^N$, where $\gamma$ is a positive constant (see [46] if $p = 2$ and [47] if $p > 2$).

Hence, we want to complete here our previous studies considering not only the singular case $p < 2$, but also the more general case of operators depending also on
$u$ and satisfying the weak monotone condition (1.5) instead of the strong monotone condition (1.11), essential in the previous papers for the results obtained there.

We recall that by the classical theory we know that even if we have no information on the initial datum $u_0$, if $f$ is sufficiently regular (for example, if it is bounded) every solution $u$ belonging to $L^\infty_0((0, T]; L^2(\Omega)) \cap L^p_0((0, T]; W^{1, p}_0(\Omega))$ becomes bounded but if $u_0$ is not regular enough we do not know if we have the starting regularity on $u$ needed to apply these classical results. Moreover, also if we assume more regularity on $u_0$, like for example that it is in $L^2(\Omega)$, in order to have the required regularity on $u$, the $L^\infty$-estimates we get by the classical theory are of different types and don’t become the decay estimates presented above when $f$ is the zero function.

Our first result is that even if the initial datum is a summable function, if $f$ is bounded then there exists a solution $u$ of (1.1) that becomes instantaneously bounded (see Sect. 2.1). We prove this regularization phenomenon at first when $\alpha_0 > 0$ (see Theorem 2.1: the absorption case) and then we show that the immediately boundedness appears also in the absence of the lower-order term $\alpha_0 u$ (see Theorem 2.2: the case without absorption) or even in the presence of the reaction term $-\alpha_0 u$ (see Theorem 2.3).

Moreover, we prove $L^\infty$-estimates that when $f$ is the zero function become the decay estimates described above.

The second aim of this paper is the study of the behavior in time of solutions that become immediately bounded, even when the initial data are merely summable functions (see Sect. 2.2 for the results).

As a matter of fact, every solution of (1.1) can be extended in a global solution $u$ defined in all $\Omega \times (0, +\infty)$ (see Definition 2.2 and Theorem 2.4) and we show that if the lower-order term $\alpha_0 u$ is not identically zero, then all the global solutions of (1.1) that become immediately bounded have the same behavior for $t$ large.

Indeed, we treat not only the case of solutions that become immediately bounded but also solutions that immediately improve their regularity but remain unbounded thus considering a wider class of solutions and of data $f$.

In all the cases studied here, we prove that if $u$ and $v$ are global solutions that become “immediately suitably regular,” where $u$ solves (1.1) and $v$ satisfies the same problem satisfied by $u$ but with initial datum $v_0$, i.e.,

$$\begin{align*}
    v_t - \operatorname{div}(a(x, t, v, \nabla v)) + \alpha_0 v &= f(x, t) \quad \text{in} \quad \Omega \times (0, +\infty), \\
    v &= 0 \quad \text{on} \quad \partial \Omega \times (0, +\infty), \\
    v(x, 0) &= v_0(x) \quad \text{on} \quad \Omega,
\end{align*}$$

(1.12)

then it results

$$\lim_{t \to +\infty} \|u(t) - v(t)\|_{L^r(\Omega)} = 0.$$  

(1.13)

for a suitable $r \geq 1$. In other words, for $t$ large the “suitably regular” solutions of (1.1) “forget their initial data” and have all the same asymptotic behavior.
The third aim of the paper is the study of time behavior of the remaining classes of solutions: the ones that do not improve their regularity with time, this can happen when \( f \) and \( u_0 \) are merely integrable functions, and the ones for which we have no information about their extra regularity.

We point out that in this context the solutions generally are not unique and hence we have the necessity to choose which solution we want to study. We recall that in order to guarantee uniqueness results further requirements on the solutions are needed, like for example to be an entropy solution or a renormalized solution, and also the operator is generally required to be an operator independent of \( u \), i.e., satisfying
\[
a(x, t, s, \xi) = a(x, t, \xi)
\]
for a.e. \((x, t) \in \Omega \times (0, +\infty)\) and for every \( s \in \mathbb{R} \) and \( \xi \in \mathbb{R}^N \). Hence, we have restricted this study to the case operators satisfying the previous assumption and we have proved that it is possible to distinguish a class of solutions, “the solutions obtained by approximation,” named “sola” (see Definition 2.3), for which we will still be able to describe the behavior in time of the solutions.

As observed in [32], “the definition of these solutions is quite natural” and is motivated by the usual way to find solutions of problems with irregular data by an approximating procedure where the irregular data are replaced by more regular functions.

We prove here that if \( u_0 \) and \( v_0 \) belong to \( L^1(\Omega) \), then the solutions \( u \) and \( v \) of, respectively, (1.1) and (1.12), which are obtained by approximation satisfying (1.13).

Moreover, we will also show that the further requirement to be a solution obtained by approximation produces uniqueness despite the fact that the data \( f \) and \( u_0 \) can be assumed to be only summable functions, thus completing the known uniqueness results on sola that require stronger monotony assumption on the operator than the weak hypothesis (1.5) made here (see Remark 2.9 for further details).

In fact, the assumption (1.14) is also responsible for other interesting phenomena (see Sect. 2.3).

For example, are also unique the solutions that although satisfy only summable initial data then become immediately bounded. Indeed, the uniqueness holds true for a larger class of solutions, eventually unbounded, but which immediately becomes suitably regular (see Theorems 2.13 and 2.14).

We notice that most of the results we prove here remain true replacing the lower-order term \( a_0 u \) in (1.1) with a more general Caratheodory function \( a_0(x, t, u, \nabla u) \) satisfying, for example
\[
a_0(x, t, s, \xi)s \geq a_0s^2, \quad a_0 \geq 0,
\]
but to make clearer the role of the lower-order term in the following results we avoid this full generality.

The plan of the paper is the following: in the next section, we state our results in all the details. In Sect. 3, we give some known and new results we need in the proofs. Finally, Sect. 4 is devoted to the proofs of all the results set out in Sect. 2.
2. Main results

We start showing that in the case of bounded forcing term and integrable initial data there exist solutions that become “instantaneously bounded.” Then, in Sect. 2.2 we will describe the behavior in time of all the solutions that become “instantaneously bounded” and finally in Sect. 2.3 we will discuss the case of operator independent of $u$.

Before stating our results, we recall that by a solution of (1.1) we mean the following.

**Definition 2.1.** A measurable function $u \in L^\infty(0, T; L^1(\Omega))$ is a solution of (1.1) if $T_k(u) \in L^p(0, T; W_0^{1,p}(\Omega))$ for every $k > 0$, $a(x, t, u, \nabla u) \in (L^1(\Omega_T))^N$ and

$$
\int\int_{\Omega_T} \left[ -u \frac{\partial \varphi}{\partial t} + a(x, t, u, \nabla u) \nabla \varphi + \alpha_0 u \varphi \right] \, dx \, dt = \int_{\Omega} u_0 \varphi(0) \, dx + \int\int_{\Omega_T} f \varphi, \tag{2.1}
$$

for every $\varphi \in W^{1,\infty}(0, T; L^{\infty}(\Omega)) \cap L^{\infty}(0, T; W_0^{1,\infty}(\Omega))$ satisfying $\varphi(T) = 0$, where $T_k(s)$ is the usual truncated function, i.e.,

$$
T_k(s) = \min\{|s|, k\} \text{ sign}(s), \tag{2.2}
$$

and $\nabla u$ is defined as in [5], i.e., it is equal to $\nabla T_k(u)$ on the set where $|u| \leq k$.

2.1. The case of bounded forcing term and integrable initial data

**Theorem 2.1.** (The case with absorption) Let $f \in L^\infty(\Omega_T)$ and $u_0 \in L^{r_0}(\Omega)$ with $r_0 \geq 1$. If (1.2)–(1.5) hold true with $\alpha_0 > 0$ and $p > \frac{2N}{N + r_0}$, then there exists a solution $u$ of (1.1) such that

$$
u(t) \in L^\infty(\Omega) \quad \text{for almost every } t \in (0, T). \tag{2.3}\n$$

Moreover, the following estimate is satisfied (for a.e. $t \in (0, T)$)

$$
\|u(t)\|_{L^\infty(\Omega)} \leq A(t) \equiv \begin{cases} c(N, \alpha, r_0) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)} \|u_0\|_{L^{r_0}(\Omega)}}{\alpha_0}, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{e^{\frac{r_0}{2}N}} \right\} & \text{if } p = 2 \\ c(N, \alpha, r_0, p) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0}, \frac{\|u_0\|^{h_0}_{L^{r_0}(\Omega)}}{t^{h_1}} \right\} & \text{if } p \neq 2 \end{cases} \tag{2.4}
$$

where $\alpha$ is as in (1.2), $\sigma = \frac{\alpha c c(r_0)}{|\Omega|^{\frac{1}{N}}}$, $c_S = c_S(N)$ is the Sobolev constant defined in (4.4) and the exponents $h_0$ and $h_1$ are defined as follows

$$
h_0 = \frac{pr_0}{N(p-2)+pr_0} \quad h_1 = \frac{N}{N(p-2)+pr_0}. \tag{2.5}\n$$

Besides, $\nabla u$ belongs to $\left[L^p(\Omega \times (t, T))\right]^N$ for every $t \in (0, T)$ and the following estimate holds true

$$
\int_{\Omega} \int_{\Omega} |\nabla u|^p \leq \frac{1}{\alpha} A(t) \left( \frac{|\Omega|}{2} A(t) + \|f\|_{L^1(\Omega_T)} \right), \tag{2.6}\n$$

for some $\alpha > 0$. This means that all the solutions become “instantaneously bounded.”
where $A(t)$ is as in (2.4).

Finally, if $p > 2$ also the following estimates hold true

$$\|u(t)\|_{L^\infty(\Omega)} \leq U(t) \equiv c(N, \alpha, r_0, p, |\Omega|) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0}, \frac{1}{t^{\frac{1}{p-2}}} \right\},$$  \hspace{1cm} (2.7)

$$\int_{t}^{T} \int_{\Omega} |\nabla u|^p \leq \frac{1}{\alpha} U(t) \left( \frac{|\Omega|}{2} U(t) + \|f\|_{L^1(\Omega_T)} \right).$$ \hspace{1cm} (2.8)

Here and throughout the paper, we adopt the convention that $\frac{1}{\infty} = 0$ and we denote with $c$ and $c(s,v)$ (respectively) positive constants and functions depending only on the variable in brackets, that can change from one line to the other.

**Remark 2.1.** We notice that the assumption $p > \frac{2N}{N+r_0}$ is a necessary condition since it is a sharp condition to have solutions that become immediately bounded when $f \equiv 0$. Moreover, for zero reaction term $f$ the previous estimates become the sharp estimates of the heat equation if $p = 2$ and those of the $p$-Laplacian otherwise (see [42,54] and the references therein). Therefore, for these estimates a sort of continuous dependence on the datum $f$ applies.

**Remark 2.2.** Notice that by the structure condition (1.3) and the regularity of $u$ proved in the previous theorem it follows that $u$ belongs also to $C((0, T]; L^2(\Omega))$.

Moreover, by the “immediately boundedness” of $u$ and the classical regularity theory we deduce

$$u \in C(\overline{\Omega} \times (0, T)), \hspace{1cm} (2.9)$$

(see [22,33]). In particular, $u$ belongs to $C((0, T]; L^r(\Omega))$ for every $r > 1$ arbitrarily fixed and estimate (2.4) holds true for every $t \in (0, T)$.

**Remark 2.3.** We point out that when $p > 2$ the $L^\infty$-estimate (2.7) together with the gradient estimate (2.8) do not depend on the initial datum $u_0$ and hence are universal estimates.

The following theorem shows that the presence of the lower-order term $\alpha_0 u$ is not essential in this instantaneous improvement of regularity since the immediately $L^\infty$-regularization holds true also if $\alpha_0 = 0$. Moreover, also in this case it is possible to derive $L^\infty$-estimates of the solutions depending only on the data.

**Theorem 2.2.** (The case without absorption) Let $f \in L^\infty(\Omega_T)$ and $u_0 \in L^{r_0}(\Omega)$ with $r_0 \geq 1$. If (1.2)–(1.5) hold true with $p > \frac{2N}{N+r_0}$, then there exists a solution $u$ of (1.1) satisfying (2.9). Moreover, for every $\rho > 0$ and $t \in (0, T)$ it results

$$\|u(t)\|_{L^\infty(\Omega)} \leq e^{\rho t} B(t)$$ \hspace{1cm} (2.10)
where

\[
B(t) \equiv \begin{cases} 
  c(N, \alpha, r_0) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho}, \frac{\|u_0\|_{L^r(\Omega)}}{\rho} \right\} & \text{if } p = 2 \\
  c(N, \alpha_p, r_0, p) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho}, \frac{\|u_0\|_{L^r(\Omega)}}{\rho} \right\} & \text{if } p \neq 2
\end{cases}
\]  

(2.11)

with \( \alpha_p = \alpha e^{-\rho(2-p)T} \) and \( \sigma \) as in estimate (2.4).

Besides, \( \nabla u \) belongs to \([L^p(\Omega \times (t, T))] \) for every \( t \in (0, T) \) and the following estimate holds true

\[
\int_t^T \int_\Omega |\nabla u|^p \leq \frac{B(t)}{\alpha} \left( e^{2\rho t} B(t) \frac{\|\Omega\|}{2} + e^{\rho T} \|f\|_{L^1(\Omega_T)} \right),
\]  

(2.12)

where \( B(t) \) is as before.

Finally, if \( p > 2 \) also the following bounds (independent of \( u_0 \)) are satisfied

\[
\|u(t)\|_{L^\infty(\Omega)} \leq e^{\rho t} B_0(t), \quad B_0(t) = c(N, \alpha, r_0, p, |\Omega|) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho}, \frac{1}{t^{\frac{1}{p-2}}} \right\}
\]  

(2.13)

\[
\int_t^T \int_\Omega |\nabla u|^p \leq \frac{B_0(t)}{\alpha} \left( e^{2\rho t} B_0(t) \frac{|\Omega|}{2} + e^{\rho T} \|f\|_{L^1(\Omega_T)} \right).
\]  

(2.14)

Remark 2.4. We point out that the estimates in Theorems 2.1 and 2.2 hold true for every solution constructed as limit of sufficiently regular approximating solutions.

Remark 2.5. Notice that if \( f \equiv 0 \) and \( p = 2 \) estimate (2.10) becomes

\[
\|u(t)\|_{L^\infty(\Omega)} \leq c(N, \alpha, r_0) \frac{\|u_0\|_{L^r(\Omega)}}{\rho} e^{\rho t},
\]  

which implies (due to the arbitrariness of \( \rho \))

\[
\|u(t)\|_{L^\infty(\Omega)} \leq c(N, \alpha, r_0) \frac{\|u_0\|_{L^r(\Omega)}}{\rho}.
\]  

(2.15)

Moreover, if otherwise \( p \neq 2 \) and \( f \equiv 0 \), by (2.10) and the arbitrariness of \( \rho \) we deduce that

\[
\|u(t)\|_{L^\infty(\Omega)} \leq c(N, \alpha, r_0, p) \frac{\|u_0\|_{L^r(\Omega)}}{t^{\frac{1}{p-2}}},
\]  

(2.16)

Finally, if \( p > 2 \) and \( f \equiv 0 \) (2.13) becomes

\[
\|u(t)\|_{L^\infty(\Omega)} \leq e^{\rho t} c(N, \alpha, r_0, p, |\Omega|) \frac{1}{t^{\frac{1}{p-2}}},
\]
which implies (due again to the arbitrariness of \( \rho \)) the following universal estimate
\[
\|u(t)\|_{L^\infty(\Omega)} \leq \frac{c(N, \alpha, r_0, p, |\Omega|)}{t^{p-2}}.
\]
Thus, all the \( L^\infty \)-estimates in Theorem 2.2 for zero data \( f \) become the sharp decay estimates (in terms of the power of \( t \) and of the dependence on \( \|u_0\|_{L^r(\Omega)} \)) known in the literature (see \([42,44,54,55]\) and the references therein).

In conclusion, even if the datum \( u_0 \) is not bounded, \( u \) becomes bounded also in the presence of a nonzero bounded reaction \( f \) and \( L^\infty \)-estimates of \( u \) hold true depending in a “continuous way on the datum \( f \)” (more precisely on the \( L^\infty \)-norm of \( f \)).

Besides, if \( f \equiv 0 \), \( 2.12 \) becomes
\[
\int_t^T \Omega |\nabla u|^p \leq c^2 \rho^T \frac{\|u_0\|_{L^2(\Omega)}}{\|u_0\|_{L^2(\Omega)}} \Bigg( \frac{|\Omega|}{2} A_s(t) \Bigg),
\]
and hence (using again the arbitrariness of \( \rho \)) we deduce the following estimate of the \( L^p \)-norm of the gradient of the solutions of \((1.1)\) with zero data \( f \)
\[
\int_t^T \Omega |\nabla u|^2 \leq c_1 \frac{\|u_0\|_{L^0(\Omega)}^2}{e^{2\sigma t} t^{N/r_0}}, \quad \text{if} \quad p = 2
\]
and otherwise \( p \neq 2 \)
\[
\int_t^T \Omega |\nabla u|^p \leq c_2 \frac{\|u_0\|_{L^0(\Omega)}^2}{t^{2h_1}}, \quad \text{if} \quad p > 2
\]

Notice that estimates (2.17)–(2.19) and (2.12) on \( \nabla u \) seem not available in the literature except in the case \( p \geq 2 \) for operators \( a \) in (1.1) independent of \( u \) (i.e., satisfying \( a(x, t, s, \xi) = a(x, t, \xi) \)) and satisfying stronger monotony assumptions which are essential in the proofs of the results (see \([46,47]\)).

We conclude this subsection studying the case when in (1.1) the absorption term \( \alpha_0 u \) is replaced by a reaction term \(-\alpha_0 u\), i.e.,
\[
\begin{cases}
  u_t - \text{div}(a(x, t, u, \nabla u)) - \alpha_0 u = f(x, t) \quad \text{in} \quad \Omega_T,
  
  u = 0 \quad \text{on} \quad \Gamma,
  
  u(x, 0) = u_0(x) \quad \text{on} \quad \Omega.
\end{cases}
\]
The following result shows that what happens is quite similar to the case without absorption. In detail, we have the following result.
Theorem 2.3. (The case with the reaction term \(-\alpha_0 u\)) Let \(f \in L^\infty(\Omega_T), \alpha_0 > 0\) and \(u_0 \in L^{r_0}(\Omega)\) with \(r_0 \geq 1\). If (1.2)–(1.5) hold true with \(p > \frac{2N}{N+r_0}\), then there exists a solution \(u\) of (2.20) satisfying (2.9). Moreover, for every \(\rho > \alpha_0\) and \(t \in (0, T)\) it results

\[
\|u(t)\|_{L^\infty(\Omega)} \leq e^{\rho t} B_{\alpha_0}(t)
\]

where

\[
B_{\alpha_0}(t) \equiv \begin{cases} 
c(N, \alpha, r_0) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho - \alpha_0}, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{e^{\sigma t}} \right\} & \text{if } p = 2 \\
c(N, \alpha_p, r_0, p) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho - \alpha_0}, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{t^{\frac{N}{r_1}}} \right\} & \text{if } p \neq 2
\end{cases}
\]

with \(\alpha_p\) and \(\sigma\) as in estimate (2.4).

Besides, \(\nabla u\) belongs to \(\left[L^p(\Omega \times (t, T))\right]^N\) for every \(t \in (0, T)\) and the following estimate holds true

\[
\int_t^T \int_\Omega |\nabla u|^p \leq \frac{B_{\alpha_0}(t)}{\alpha} \left[ \left( \frac{e^{2\rho t}}{2} + \alpha_0 e^{2\rho T} \right) B_{\alpha_0}(t)|\Omega| + e^{\rho T} \|f\|_{L^1(\Omega_T)} \right], (2.23)
\]

where \(B_{\alpha_0}(t)\) is as before.

Finally, if \(p > 2\) also the following bounds (independent of \(u_0\)) are satisfied

\[
\|u(t)\|_{L^\infty(\Omega)} \leq e^{\rho t} B_{0, \alpha_0}(t), \quad B_{0, \alpha_0}(t) = c(N, \alpha, r_0, p, |\Omega|) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho - \alpha_0}, \frac{1}{t^{\frac{N}{p-2}}} \right\} (2.24)
\]

\[
\int_t^T \int_\Omega |\nabla u|^p \leq \frac{B_{0, \alpha_0}(t)}{\alpha} \left[ \left( \frac{e^{2\rho t}}{2} + \alpha_0 e^{2\rho T} \right) B_{0, \alpha_0}(t)|\Omega| + e^{\rho T} \|f\|_{L^1(\Omega_T)} \right]. (2.25)
\]

2.2. Time behavior of the solutions

In the previous sections, we have considered solutions of our problem (1.1) in \(\Omega_T\). In this subsection, we show that there exist solutions in all the set \(\Omega_\infty\) (global solutions) and we study the behavior in time of these global solutions. To this aim, we give the following definition.

Definition 2.2. We say that \(u\) is a global solution of (1.1) or, equivalently, that \(u\) is a solution of

\[
\begin{cases} 
\frac{\partial}{\partial t} u - \text{div}(a(x, t, u, \nabla u)) + \alpha_0 u = f(x, t) & \text{in } \Omega_\infty \equiv \Omega \times (0, \infty), \\
u = 0 & \text{on } \partial \Omega \times (0, +\infty), \\
u(x, 0) = u_0(x) & \text{on } \Omega.
\end{cases}
\]

(2.26)

if \(u\) is a solution of (1.1) (according to Definition 2.1) for every arbitrarily fixed \(T > 0\).
Moreover, we denote by a “global solution of (1.1) relative to the datum \( f \) and to the initial datum \( v_0 \)” \((v_0 \in L^{r_0}(\Omega) \text{ with } r_0 \geq 1)\) a global solution \( v \) (according to the above definition) of the following problem

\[
\begin{aligned}
&v_t - \text{div}(a(x, t, v, \nabla v)) + a_0 v = f(x, t) \quad \text{in } \Omega_\infty, \\
v &= 0 \quad \text{on } \partial \Omega \times (0, +\infty), \\
v(x, 0) &= v_0(x) \quad \text{on } \Omega.
\end{aligned}
\] (2.27)

We show now that under the structure assumptions (1.2)–(1.5), even if the data \( f \) and \( u_0 \) are only summable functions, our problem always admits global solutions. Moreover, if \( f \) is bounded and \( p \) not too small, then there exist also solutions which immediately become bounded. In detail, we have the following result.

**Theorem 2.4.** Assume that \( f \) belongs to \( L^1_{\text{loc}}([0, +\infty); L^1(\Omega)) \) and that (1.2)–(1.6) hold true with \( T = +\infty \). Then, there exists a global solution of (1.1).

Moreover, if \( a(x, t, s, \xi) \equiv a(x, t, \xi) \) then \( u \) belongs to \( C_{\text{loc}}([0, +\infty); L^1(\Omega)) \).

Finally, if \( p > \frac{2N}{N+r_0} \) and \( f \in L^2_{\text{loc}}([0, +\infty); L^\infty(\Omega)) \), then \( u \) belongs to

\[
L^\infty_{\text{loc}}([0, +\infty); L^\infty(\Omega)) \cap L^p_{\text{loc}}([0, +\infty); W^{1,p}_0(\Omega)) \cap C_{\text{loc}}([0, +\infty); L^r(\Omega))
\]

for every \( r \geq 1 \), while if we also assume \( a_0 > 0 \) and \( f \in L^\infty(\Omega_\infty) \cap L^1(\Omega_\infty) \) then \( u \) belongs also to

\[
L^\infty(\Omega \times [t_0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \cap C([t_0, +\infty); L^r(\Omega))
\]

for every \( t_0 > 0 \) and \( r \geq 1 \).

We observe that generally these global solutions are not unique (see next section for further details). Anyway, we show now that if the lower-order term \( a_0 u \) is not zero, all the solutions that become “immediately bounded” have the same asymptotic behavior for \( t \to +\infty \) and this “asymptotic behavior” is the same also for all the global solutions verifying different initial data. In other words, the solutions for large value of \( t \) “forget” their initial data.

More in detail, we have the following result.

**Theorem 2.5.** Let (1.2)–(1.4) hold true with \( T = +\infty \) and \( h \in L^{p'}(\Omega_\infty) \). Assume \( a_0 > 0 \) and that \( u \) and \( v \) are two global solutions of (1.1) relative to the same datum \( f \in L^1_{\text{loc}}([0, +\infty); L^1(\Omega)) \) and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\). If there exist \( t_0 > 0 \) and \( r \geq 2 \) such that \( u \) and \( v \) belong to \( L^\infty(\Omega \times [t_0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \cap C([t_0, +\infty); L^r(\Omega)) \), then it results

\[
\lim_{t \to +\infty} \|u(t) - v(t)\|_{L^r(\Omega)} = 0.
\] (2.28)

**Remark 2.6.** It is worth to notice that under the structure assumptions of the previous theorem, if we choose \( p > \frac{2N}{N+r_0} \), \( f \in L^\infty(\Omega_\infty) \cap L^1(\Omega_\infty) \) and we assume also the
weak monotone condition (1.5), then by Theorem 2.4 for every choice of initial data \( u_0 \) and \( v_0 \) in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\) there exist at least a global solution \( u \) of (1.1) and a global solution \( v \) of (2.27) belonging to \( L^\infty(\Omega \times (t_0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \) \( \cap C([t_0, +\infty); L^r(\Omega)) \) for every arbitrarily fixed \( t_0 > 0 \) and \( r \geq 1 \).

Hence, by Theorem 2.5, all these regular global solutions have the same asymptotic behavior (for \( t \to +\infty \)) free from their initial data and the convergence (2.28) holds true for every \( r \geq 1 \).

Indeed, if to the assumptions of Theorem 2.5 we add the boundedness of the reaction term \( f \), we obtain that every solution in \( L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \) \( \cap L^\infty(\Omega \times [t_0, +\infty)) \) belongs also to \( C([t_0, +\infty); L^r(\Omega)) \) for every \( r \geq 1 \) and satisfies (2.28). In detail, it results.

**Corollary 2.1.** Let (1.2)–(1.4) hold true with \( T = +\infty \) and \( h \in L^{p'}(\Omega_\infty) \). Assume \( \alpha_0 > 0 \) and that \( u \) and \( v \) are two global solutions of (1.1) relative to the same datum \( f \in L^\infty(\Omega_\infty) \) and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\). If there exists \( t_0 > 0 \) such that \( u \) and \( v \) belong to \( L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \) \( \cap L^\infty(\Omega \times [t_0, +\infty)) \) then \( u \) and \( v \) belong to \( C([t_0, +\infty); L^r(\Omega)) \) for every \( r \geq 1 \) and (2.28) holds true (for every \( r \geq 1 \)).

We observe that even if the global solutions \( u \) and \( v \) are not locally bounded (and hence the previous results cannot apply) it is still possible to prove that they exhibit the same asymptotic behavior if they are “sufficiently regular” as the following result shows.

**Theorem 2.6.** Let (1.2)–(1.4) hold true with \( T = +\infty \) and \( h \in L^{p'}(\Omega_\infty) \). Assume \( \alpha_0 > 0 \) and that \( u \) and \( v \) are two global solutions of (1.1) relative to the same datum \( f \) and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\). If there exists \( t_0 > 0 \) such that \( u \) and \( v \) belong to \( L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \) \( \cap L^\infty(\Omega \times [t_0, +\infty)) \) \( \cap L^\infty(\Omega_\infty) \) and \( f \) belongs to \( L^{p'}(\Omega) \), then \( u \) and \( v \) belong to \( C_{loc}([t_0, +\infty); L^2(\Omega)) \) and it results

\[
\lim_{t \to +\infty} \| u(t) - v(t) \|_{L^2(\Omega)} = 0.
\]

**Remark 2.7.** We observe that the study of the smoothing effect and time behavior of the solutions to special classes of operators of \( p \)-Laplacian type in the absence of reaction terms and in different geometric settings can be found in [13–16,19,28].

We conclude this section studying the particular case of operator \( a \) independent of \( u \) since in this case many other further interesting properties of the solutions appear.

2.3. The case of operator \( a \) independent of \( u \)

In this subsection, we prove that under the following condition

\[
a(x, t, s, \xi) = a(x, t, \xi) \quad \text{for every } (s, \xi) \in \mathbb{R} \times \mathbb{R}^N \quad \text{and a.e. } (x, t) \in \Omega_T,
\]

(2.29)
many interesting further properties of the solutions of (1.1) appear concerning not only their behavior in time but also their uniqueness properties.

As a first result, we prove that the presence of a bounded reaction term \( f \) allows to take \( r = +\infty \) in (2.28). More in detail, we have the following result.

**Theorem 2.7.** Assume that (1.2)–(1.7) and (2.29) hold true with \( T = +\infty \) and \( \alpha_0 > 0 \). Let \( u \) and \( v \) be two global solutions of (1.1) relative to the same datum \( f \) and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\). If these solutions belong to \( L^p_{loc}(I_0, +\infty); W^{1,p}_0(\Omega)) \cap L^\infty_{loc}(I_0, +\infty); L^\infty(\Omega)) \) (for an arbitrarily fixed \( t_0 > 0 \)) then \( u \) and \( v \) belong to \( C(\overline{\Omega} \times [t_0, +\infty)) \) and it results

\[
\lim_{t \to +\infty} \| u(t) - v(t) \|_{L^\infty(\Omega)} = 0. \tag{2.30}
\]

Moreover, the following estimate holds true

\[
\| u(t) - v(t) \|_{L^\infty(\Omega)} \leq \frac{\| u(t_0) - v(t_0) \|_{L^\infty(\Omega)}}{e^{\alpha_0(t-t_0)}} \quad \text{for every } t > t_0. \tag{2.31}
\]

We point out that in the special autonomous case

\[
a(x, t, s, \xi) = a(x, \xi) \quad f(x, t) = f(x) \tag{2.32}
\]

(for a.e. \( x \in \Omega \) and \( t \geq 0 \) and for all \( s \in \mathbb{R} \) and \( \xi \in \mathbb{R}^N \)) the previous theorem implies that for large value of \( t \) the “suitably regular” global solutions behave as the solution \( w \in W^{1,p}_0(\Omega) \cap L^\infty(\Omega) \) of the associated stationary elliptic problem

\[
\begin{cases}
-\text{div}(a(x, \nabla w)) + \alpha_0 w = f(x) & \text{in } \Omega, \\
w = 0 & \text{on } \partial\Omega. \tag{2.33}
\end{cases}
\]

Moreover, it is also possible to estimate the difference between these global solutions of (1.1) and the stationary solution \( w \). In detail, we have the following result.

**Corollary 2.2.** Let (1.2)–(1.7) hold true with \( T = +\infty \) and \( \alpha_0 > 0 \). If (2.32) is satisfied then every global solution \( u \) of (1.1) belonging to \( L^p_{loc}(I_0, +\infty); W^{1,p}_0(\Omega)) \cap L^\infty_{loc}(I_0, +\infty); L^\infty(\Omega)) \) \((\text{where } t_0 > 0)\) belongs to \( C(\overline{\Omega} \times [t_0, +\infty)) \) and satisfies

\[
\lim_{t \to +\infty} \| u(t) - w \|_{L^\infty(\Omega)} = 0,
\]

where \( w \) is the unique solution of (2.33) belonging to \( W^{1,p}_0(\Omega) \cap L^\infty(\Omega) \).

Moreover, the following estimate holds

\[
\| u(t) - w \|_{L^\infty(\Omega)} \leq \frac{\| u(t_0) - w \|_{L^\infty(\Omega)}}{e^{\alpha_0(t-t_0)}} \quad \text{for every } t > t_0. \tag{2.34}
\]

**Remark 2.8.** We recall that analogous results where proved in [46,47] when \( p \geq 2 \) and under stronger monotony assumptions on the operator \( a(x, \xi) \). Hence, the previous result completes the cited ones revealing that the same phenomenon appears in the singular case \( p < 2 \) and for a more general class of “weak monotone” parabolic equations.
Until now, we have described the behavior of suitably regular solutions considering different “type of regularity” (for example, immediately boundedness or gradient in $L^p$).

We show now that it is possible to say something also when the solutions generally do not increase their regularity, as for example when $f$ and $u_0$ are only summable functions, or when we do not have any information on the regularity of the solutions.

As a matter of fact, in all these cases it is possible distinguish a class of solutions, “the solutions obtained by approximation,” for which we will still be able to describe their behavior in time. Moreover, we will also show that the further requirement to be a solution obtained by approximation produces uniqueness despite the fact that the data $f$ and $u_0$ can be assumed to be only summable functions.

More in detail, let us define what we mean by a “solution constructed by approximation.”

**Definition 2.3.** A solution $u$ of (1.1) is obtained by approximation (sola) if it is the a.e. limit in $\Omega_T$ of the solutions $u_n \in L^\infty(\Omega_T) \cap C([0, T]; L^2(\Omega)) \cap L^p(0, T; W^{1,p}_0(\Omega))$ (denoted “approximating solutions”) of the following (approximating) problems

$$\begin{cases}
(u_n)_t - \text{div}(a(x, t, \nabla u_n)) + \alpha_0 u_n = f_n(x, t) \quad \text{in } \Omega_T, \\
u_n = 0 \quad \text{on } \Gamma, \\
u_n(x, 0) = u_{0,n} \quad \text{on } \Omega,
\end{cases}$$

where $f_n$ and $u_{0,n}$ satisfy

$$f_n \in L^\infty(\Omega_T), \quad f_n \to f \quad \text{in } L^1(\Omega_T),$$

$$u_{0,n} \in L^\infty(\Omega), \quad u_{0,n} \to u_0 \quad \text{in } L^1(\Omega).$$

Our first result on “sola” is the following.

**Theorem 2.8.** Let (1.2)–(1.5) and (2.29) hold true. Let $f \in L^1(\Omega_T)$ and $u_0 \in L^{r_0}(\Omega)$ with $r_0 \geq 1$. Then, there exists only one solution $u$ of (1.1) constructed by approximation. Moreover, it results

$$u \in C([0, T]; L^1(\Omega))$$

and the following “estimate of continuous dependence from the data” holds true for every $t \in (0, T)$

$$\|u(t) - v(t)\|_{L^1(\Omega)} \leq \|u_0 - v_0\|_{L^1(\Omega)} + \|f - g\|_{L^1(\Omega_t)},$$

where $v$ is the (unique) solution constructed by approximation of problem (1.1) which assume initial datum $v_0 \in L^1(\Omega)$ and forcing term $g \in L^1(\Omega_T)$, i.e., $v$ is the solution constructed by approximation of the following problem

$$\begin{cases}
v_t - \text{div}(a(x, t, \nabla v)) + \alpha_0 v = g \quad \text{in } \Omega_T, \\
v = 0 \quad \text{on } \Gamma, \\
v(x, 0) = v_0 \quad \text{on } \Omega.
\end{cases}$$
Remark 2.9. We notice explicitly that in Theorem 2.8 we have assumed $\alpha_0 \geq 0$ and hence the uniqueness of sola holds true also in the absence of the lower-order term $\alpha_0 u$.

We also point out that the previous uniqueness result completes the result in [20] where when $p > 2 - \frac{1}{N+1}$ the uniqueness of solutions obtained by approximation is proved assuming the following further structural assumptions

$$[a(x, t, \xi) - a(x, t, \eta)] [\xi - \eta]^p \quad \text{if} \quad 2 \leq p < +\infty,$$

$$[a(x, t, \xi) - a(x, t, \eta)] [\xi - \eta]^2 \quad \text{if} \quad 2 - \frac{1}{N+1} < p < 2.$$

We prove now that if the forcing term $f$ is bounded and $p$ is not too small then the unique solution of (1.1) obtained by approximation is a solution which “immediately becomes bounded.” In detail, we have

Theorem 2.9. Let (1.2)–(1.5) and (2.29) hold true with $p > \frac{2N}{N+r_0}$. Let $f \in L^\infty(\Omega_T)$ and $u_0 \in L^0(\Omega)$ with $r_0 \geq 1$. Then, there exists only one solution $u$ of (1.1) constructed by approximation belonging to $L^\infty_{loc}((0, T]; L^\infty(\Omega)) \cap L^p_{loc}((0, T]; W^{1,p}_0(\Omega)) \cap C([0, T]; L^1(\Omega))$. Moreover, $u$ satisfies the estimates of Theorem 2.1 if $\alpha_0 > 0$ and the estimates of Theorem 2.2 if $\alpha_0 = 0$.

Indeed, by the following theorem we can affirm that the solutions obtained by approximations have also a unique extension to a global solution obtained by approximation and all these global solutions exhibit the same behavior for large values of $t$, independently from the initial data that they assume. We recall that here by a global solution defined by approximation we mean the following

Definition 2.4. A function $u$ is a global solution of (1.1) obtained by approximation (or equivalently is a solution of (2.26) obtained by approximation) if for every arbitrarily fixed $T > 0$, $u$ is a solution of (1.1) obtained by approximation (according to Definition 2.3).

Theorem 2.10. Let (1.2)–(1.5) and (2.29) hold true with $T = +\infty$. Assume $u_0 \in L^r_0(\Omega)$ with $r_0 \geq 1$ and $f \in L^1_{loc}((0, +\infty); L^1(\Omega))$. Then, there exists a unique global solution $u$ of (1.1) obtained by approximation. Moreover, $u$ belongs to $C_{loc}((0, +\infty); L^1(\Omega))$.

Furthermore, if $v \in C_{loc}((0, +\infty); L^1(\Omega))$ is the global solution obtained by approximation of (2.40) with $g \in L^1_{loc}((0, +\infty); L^1(\Omega))$ and $v_0 \in L^r_0(\Omega)$, then the estimate of continuous dependence from the data (2.39) holds true for every $t > 0$.

Finally, if $\alpha_0 > 0$ and $g = f$ (hence now $v$ is the unique global solution obtained by approximation of (2.27)) then the following estimate holds true for a.e. $t > 0$

$$\|u(t) - v(t)\|_{L^r(\Omega)} \leq c \frac{\|u_0 - v_0\|_{L^r_0(\Omega)}}{e^{\alpha_0 t}} \quad \text{for every} \quad 1 \leq r \leq r_0, \quad (2.41)$$

where $c = |\Omega|^\frac{1}{r} \frac{1}{\alpha_0}$. In particular, it results

$$\lim_{t \to +\infty} \|u(t) - v(t)\|_{L^1(\Omega)} = 0. \quad (2.42)$$
**Remark 2.10.** We point out explicitly that by \((2.42)\) it follows that all these global solutions obtained by approximation have the same asymptotic behavior at infinity even if they satisfy different initial data.

We show now that if \(p\) is not too small and in the presence of a more regular datum \(f\) the unique global solution of \((1.1)\) obtained by approximation is a solution which “immediately increases its regularity.” In detail, we have

**Theorem 2.11.** Let \((1.2)-(1.5)\) and \((2.29)\) hold true with \(T = +\infty, p > \frac{2N}{N+r_0}\) and \(f \in L_{loc}^\infty([0, +\infty); L^\infty(\Omega))\). Then, there exists a unique global solution \(u\) of \((1.1)\) obtained by approximation belonging to

\[
C_{loc}([0, +\infty); L^1(\Omega)) \cap L_{loc}^\infty([0, +\infty); L^\infty(\Omega)) \cap L_{loc}^p((0, +\infty); W_{0}^{1,p}(\Omega)) \cap \mathcal{C}_{loc}((0, +\infty); L'(\Omega))
\]

for every \(r \geq 1\).

Moreover, if \(f \in L^\infty(\Omega_\infty) \cap L^1(\Omega_\infty)\) and \(\alpha_0 > 0\) then \(u\) belongs also to

\[
L^\infty(\Omega \times [t_0, +\infty)) \cap L^p(t_0, +\infty; W_0^{1,p}(\Omega)) \cap \mathcal{C}([t_0, +\infty); L'(\Omega))
\]

for every \(t_0 > 0\) and \(r \geq 1\).

Indeed, even if a solution is not obtained by approximation, if it is sufficiently regular (belonging to \(L_{loc}^p([0, +\infty); W_0^{1,p}(\Omega))\)), then it has the same asymptotic behavior for \(t \to +\infty\) of the solutions constructed by approximation. As a matter of fact, it results.

**Theorem 2.12.** Let \((1.2)-(1.5)\) and \((2.29)\) hold true with \(T = +\infty\). Assume \(\alpha_0 > 0, f \in L_{loc}^1([0, +\infty); L^1(\Omega)), u_0 \in L^1(\Omega)\) and \(v_0 \in L^1(\Omega)\). If \(u \in C_{loc}([0, +\infty); L^1(\Omega))\) is the global solution obtained by approximation of \((1.1)\) and if \(v\) is a global solution of \((2.27)\) belonging to \(L_{loc}^p([0, +\infty); W_0^{1,p}(\Omega))\) then the following estimate holds true

\[
\|u(t) - v(t)\|_{L^1(\Omega)} \leq \frac{\|u_0 - v_0\|_{L^1(\Omega)}}{e^{\alpha_0 t}} \quad \text{for every } t > 0. \quad (2.43)
\]

In particular, the limit \((2.42)\) is satisfied.

Indeed, the previous result reveals that if \(\alpha_0 > 0\) then all the “sufficiently” regular solutions are unique and coincide with the solutions obtained by approximations. As a matter of fact, an immediate consequence of estimate \((2.43)\) (applied with \(u_0 = v_0\)) is the following result.

**Corollary 2.3.** Let \((1.2)-(1.5)\) and \((2.29)\) hold true with \(T = +\infty\). Assume \(f \in L_{loc}^1([0, +\infty); L^1(\Omega)), u_0 \in L^1(\Omega)\) and \(\alpha_0 > 0\). If \(u\) is a global solution of \((1.1)\) belonging to \(L_{loc}^p([0, +\infty); W_0^{1,p}(\Omega))\) then \(u\) is the unique global solution of \((1.1)\) obtained by approximation.

Hence, problem \((1.1)\) can be solved by only one global solution belonging to the space \(L_{loc}^p([0, +\infty); W_0^{1,p}(\Omega))\).
Moreover, if $v_0 \in L^1(\Omega)$ and $v$ is the unique global solution of (2.27) in $L^p_{\text{loc}}([0, +\infty); W^{1,p}_0(\Omega))$ and if $u$ is, as above, the unique global solution of (1.1) belonging to $L^p_{\text{loc}}([0, +\infty); W^{1,p}_0(\Omega))$ then estimates (2.43) and (2.42) hold true.

We notice that in the previous uniqueness result it was essential the requirement that $\alpha_0 > 0$, otherwise the crucial estimate (2.43) fails. We prove now that the uniqueness of the “sufficiently regular” solutions holds true even if $\alpha_0 = 0$.

Moreover, we prove that it is sufficient that the solution becomes immediately “sufficiently regular” (i.e., it is not necessary the regularity “up to zero”). In detail, we have the following result.

**Theorem 2.13.** Let (1.3)–(1.5) and (2.29) hold true. Assume $f \in L^1(\Omega_T)$ and $u_0 \in L^1(\Omega)$. Then, there is at most one solution of (1.1) belonging to $L^p_{\text{loc}}([0, T]; W^{1,p}_0(\Omega)) \cap C([0, T]; L^1(\Omega))$.

Consequently, if (1.3)–(1.5) and (2.29) hold true with $T = +\infty$ and $f \in L^1_{\text{loc}}([0, +\infty); L^1(\Omega))$ then there is at most one global solution of (1.1) belonging to $L^p_{\text{loc}}([0, +\infty); W^{1,p}_0(\Omega)) \cap C_{\text{loc}}([0, +\infty); L^1(\Omega))$.

An immediate consequence of Theorems 2.13 and 2.4 is the following result.

**Theorem 2.14.** Let (1.2)–(1.6) and (2.29) hold true with $T = +\infty$ and $p > \frac{2N}{N+r_0}$. Assume $f \in L^\infty_{\text{loc}}([0, +\infty); L^\infty(\Omega))$. Then, there exists only one global solution $u$ belonging to

$$L^\infty_{\text{loc}}([0, +\infty); L^\infty(\Omega)) \cap L^p_{\text{loc}}([0, +\infty); W^{1,p}_0(\Omega)) \cap C_{\text{loc}}([0, +\infty); L^1(\Omega)) \cap C([0, +\infty); L^r(\Omega))$$

for every $r \geq 1$.

Moreover, if we also assume $\alpha_0 > 0$ and $f \in L^\infty(\Omega_\infty) \cap L^1(\Omega_\infty)$, then $u$ belongs also to

$$L^\infty(\Omega \times [t_0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \cap C([t_0, +\infty); L^r(\Omega))$$

for every $t_0 > 0$ and $r \geq 1$. Finally, $u$ is also the unique global solution obtained by approximation.

**Remark 2.11.** We recall, that we have proved above that under the assumptions of the previous theorem there exists a global solution which immediately increases its regularity which is the unique solution obtained by approximation. A priori we do not know if there exist other global solutions which immediately increase their regularity and that are not solutions obtained by approximation. The previous result allows to conclude that there exists one and only one global solution which immediately become regular. Thus, such a unique global solution which becomes immediately regular is also the unique global solution obtained by approximation.
3. Preliminary results

In this section, we give some known and new results which will be essential in the proofs of the results presented here and that can be of interest in themselves.

We start recalling some results about $L^\infty$-decay estimates proved in [42] which substantially allow to obtain decays estimates simply by suitable integral estimates (see [48] for a brief description of this method). The proofs of these results make use of a technical Lemma proved in [50] together with a classical Lemma (see Lemma 3.1) often used to prove $L^\infty$-results. We point out that there are different methods to prove decay estimates. For example, a classical method (completely different from that used here) is the use of suitable Sobolev logarithmic inequalities which reflect the operator involved in the problem (see for example [19,27,54] and the references therein).

In detail, let us define

$$G_k(s) = (|s| - k)_+ \text{sign}(s).$$

(3.1)

We have the following results.

**Theorem 3.1.** (Theorem 2.1 in [42]) Assume that

$$u \in C((0, T); L^r(\Omega)) \cap L^b(0, T; L^q(\Omega)) \cap C([0, T); L^r_0(\Omega))$$

(3.2)

where $\Omega$ is an open set of $\mathbb{R}^N$, (not necessarily bounded), $N \geq 1$, $0 < T \leq +\infty$ and

$$1 \leq r_0 < r < q \leq +\infty, \quad b_0 < b < q, \quad b_0 = \frac{(r - r_0)}{1 - \frac{r}{q}}.$$  

(3.3)

Suppose that $u$ satisfies the following integral estimates for every $k > 0$

$$\int_\Omega |G_k(u)|^r(t_2)dx - \int_\Omega |G_k(u)|^r(t_1)dx + c_1 \int_{t_1}^{t_2} \|G_k(u)(\tau)\|_{L^b(\Omega)} d\tau \leq 0$$

for every $0 < t_1 < t_2 < T$  

(3.4)

$$\|G_k(u)(t)\|_{L^{r_0}(\Omega)} \leq c_2 \|G_k(u)(t_0)\|_{L^{r_0}(\Omega)}$$

for every $0 \leq t_0 < t < T$,  

(3.5)

where $c_1$ and $c_2$ are positive constants independent of $k$. Finally, let us define

$$u_0 \equiv u(x, 0) \in L^{r_0}(\Omega).$$

(3.6)

Then, there exists a positive constant $C_1$ (see Formula (4.11) in [42]) depending only on $N$, $c_1$, $c_2$, $r$, $r_0$, $q$ and $b$ such that

$$\|u(t)\|_{L^\infty(\Omega)} \leq C_1 \frac{|u_0|_{L^{r_0}(\Omega)}^{h_0}}{t^{h_1}}$$

for every $t \in (0, T)$,  

(3.7)

where

$$h_1 = \frac{1}{b - (r - r_0) - \frac{rb}{q}}, \quad h_0 = h_1 \left(1 - \frac{b}{q}\right) r_0.$$  

(3.8)
Moreover, if $\Omega$ has finite measure we have an exponential decay if $b = r$ and universal bounds if $b > r$. More in detail, we have the following result.

**Theorem 3.2.** (Theorem 2.2 in [42]) Let the assumptions of Theorem 3.1 hold true. If $\Omega$ has finite measure and $b = r$, the following exponential decay occurs

$$\|u(t)\|_{L^\infty(\Omega)} \leq C_2 \frac{\|u_0\|_{L^r(\Omega)}}{t^{h_1} e^{\sigma t}}$$

for every $t \in (0, T)$, (3.9)

where $C_2$ (see Formula (4.17) in [42]) is a positive constant (depending only on $N, c_1, c_2, r, r_0$ and $q$), $u_0$ is as in (3.6), $h_1$ is as in (3.8), i.e., (recalling that here $r = b$)

$$h_1 = \frac{1}{r_0 \left(1 - \frac{q}{r_0} \right)},$$

(3.10)

and

$$\sigma = \frac{c_1 \kappa}{4(r - r_0)|\Omega|^{1 - \frac{r}{q}}}, \quad \kappa \text{ arbitrarily fixed in } \left(0, 1 - \frac{r_0}{r} \right),$$

(3.11)

where $|\Omega|$ denotes the measure of $\Omega$. If otherwise $\Omega$ has finite measure and $b > r$, we have the following universal bound

$$\|u(t)\|_{L^\infty(\Omega)} \leq \frac{C_2}{t^{h_2}}$$

for every $t \in (0, T)$, (3.12)

where

$$h_2 = h_1 + \frac{h_0}{b - r} = \frac{1}{b - r},$$

(3.13)

and $C_2$ (see Formula (4.19) in [42]) is a constant depending only on $r, r_0, q, b, c_1, c_2$ and the measure of $\Omega$.

**Remark 3.1.** The previous Theorems hold true also if we replace assumption (3.5) with the following weaker assumption

$$\left\{ \begin{array}{l}
\|G_k(u)(t)\|_{L^{r_0}(\Omega)} \leq c_2 \|G_k(u)(t_0)\|_{L^{r_0}(\Omega)}, \quad \forall \ 0 < t_0 < t < T, \\
\|G_k(u)(t)\|_{L^{r_0}(\Omega)} \leq c_0, \quad \forall \ 0 < t < T,
\end{array} \right.$$  

(3.14)

and in this last case all the previous decay estimates hold true with the value $\|u_0\|_{L^{r_0}(\Omega)}$ replaced by $\frac{c_0}{c_2}$. For details, see Remark 2.4 in [42].

The following three theorems are generalizations of Theorems 3.1 and 3.2 and will be proved at the end of this section.

**Theorem 3.3.** Let the assumptions of Theorem 3.1 be satisfied with the only change that now inequalities (3.4) and (3.5) are satisfied only for every $k \geq \sigma_0$, where $\sigma_0$ is a positive constant. Then, $u(t)$ belongs to $L^\infty(\Omega)$ for every $t > 0$ and the following estimate holds true

$$\|u(t)\|_{L^\infty(\Omega)} \leq C_0 \max \left\{ \sigma_0, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{t^{h_1}} \right\}$$

for every $t \in (0, T)$ (3.15)
where \( u_0 \) is as in (3.6), the exponents \( h_0 \) and \( h_1 \) are as in (3.8) and \( C_0 = \max\{2, C_1\} \) with \( C_1 \) as in Theorem 3.1.

**Theorem 3.4.** Under the assumptions of Theorem 3.3, if \( \Omega \) has finite measure and \( b = r \) then the following estimate occurs

\[
\|u(t)\|_{L^\infty(\Omega)} \leq C_3 \max\left\{ \sigma_0, \frac{\|u_0\|_{L^r_0(\Omega)}}{t^{h_1 e^{\sigma t}}} \right\} \quad \text{for every } t \in (0, T), \tag{3.16}
\]

where \( u_0 \) is as in (3.6), the exponent \( h_1 \) is as in (3.10), \( \sigma \) is as in (3.11) and \( C_3 = \max\{2, C_2\} \) (\( C_2 \) as in Theorem 3.2).

**Theorem 3.5.** Under the assumptions of Theorem 3.3, if \( \Omega \) has finite measure and \( b > r \) then the following estimate occurs

\[
\|u(t)\|_{L^\infty(\Omega)} \leq C_4 \max\left\{ \sigma_0, \frac{1}{t^{h_2}} \right\} \quad \text{for every } t \in (0, T), \tag{3.17}
\]

where the exponent \( h_2 \) is as in (3.13) and \( C_4 = \max\{2, C_\sharp\} \) is a constant independent of \( u_0 \) (\( C_\sharp \) is as in Theorem 3.2).

In the proofs of Theorems 3.3–3.5 below, we will use the following lemma which, as recalled above, is a very useful tool in proving boundedness results.

**Lemma 3.1.** (Lemma 5.6, Chapter 2 in [33]) Assume that a sequence \( \{Y_m\}_{m \in \mathbb{N} \cup \{0\}} \) of nonnegative real numbers satisfies

\[
Y_{m+1} \leq CB^m Y_m^{1+\delta} \quad \text{for every } m \in \mathbb{N} \cup \{0\}, \tag{3.18}
\]

and

\[
Y_0 \leq C^{-\frac{1}{\delta}} B^{-\frac{1}{\delta^2}}, \tag{3.19}
\]

where \( C \) and \( \delta \) are positive given constants and \( B \geq 1 \). Then, it follows that

\[
Y_m \to 0 \quad \text{as } m \to \infty.
\]

To be self-contained, we recall also the following two results, proved, respectively, in [38,43], which we will use in the proofs of the asymptotic behavior of the solutions.

**Theorem 3.6.** (Theorem 2.8 of [43]) Let \( u \) be in \( C((0, T); L^r(\Omega)) \cap L^\infty(0, T; L^{r_0}(\Omega)) \) where \( 0 < r \leq r_0 < +\infty \). Suppose also that \( |\Omega| < +\infty \) if \( r \neq r_0 \) (no assumption on \( |\Omega| \) are needed if \( r = r_0 \)). If \( u \) satisfies

\[
\int_\Omega |u|^r(t_2) \, dx - \int_\Omega |u|^r(t_1) \, dx + c_1 \int_{t_1}^{t_2} \|u(\tau)\|_{L^r_0(\Omega)} \, d\tau \leq 0
\]

for every \( 0 < t_1 < t_2 < T \), \( \tag{3.20} \)
and there exists \( u_0 \in L^{r_0}(\Omega) \) such that
\[
\| u(t) \|_{L^{r_0}(\Omega)} \leq c_2 \| u_0 \|_{L^{r_0}(\Omega)} \text{ for almost every } t \in (0, T),
\]
where \( c_i (i=1,2) \) are real positive constants, then the following estimate holds true
\[
\| u(t) \|_{L^{r}(\Omega)} \leq c_4 \frac{\| u_0 \|_{L^{r_0}(\Omega)}}{e^{\sigma t}} \text{ for every } 0 < t < T
\]
where
\[
c_4 = \begin{cases} 
    c_2 |\Omega|^{\frac{1}{r} - \frac{1}{r_0}} & \text{if } r \neq r_0 \\
    1 & \text{if } r = r_0 
\end{cases} \quad \sigma = \frac{c_1}{r}.
\]

**Theorem 3.7.** (Proposition 3.2 of [38]) Assume \( T_0 \in (t_0, +\infty] \) where \( t_0 \geq 0 \) and let \( \Psi(t) \) a continuous and nonnegative function defined on \([t_0, T_0)\) verifying
\[
\Psi(t_2) - \Psi(t_1) + M \int_{t_1}^{t_2} \Psi(t) dt \leq \int_{t_1}^{t_2} g(t) dt
\]
for every \( t_0 < t_1 < t_2 < T_0 \) where \( M \) is a positive constant and \( g \) is a nonnegative function belonging to \( L^1_{loc}([t_0, T_0)) \). Then, it results
\[
\Psi(t) \leq \Psi(t_0)e^{-M(t-t_0)} + \int_{t_0}^{t} g(s) ds \quad \text{for every } t \in (t_0, T_0).
\]

We conclude this section by proving Theorems 3.3–3.5.

**Proof of Theorem 3.3.** Proceeding exactly as in the proof of the Theorem 2.1 in [42] (recalled above as Theorem 3.1), we deduce that the following inequality holds (see (4.7) in [42])
\[
Y_{m+1} \leq CB^m Y_m^{1+\delta} \quad \text{for every } m \in \mathbb{N} \cup \{0\}.
\]
(3.24)

where
\[
Y_m = \sup_{s \in [t_m, t]} \| (|u| - k_m) + (s) \|_{L^{r_0}(\Omega)},
\]
\[
k_m = k \left( 1 - \frac{1}{2^{m+1}} \right), \quad t_m = t \left( 1 - \frac{1}{2^{m+1}} \right),
\]
\[
\delta = \frac{\gamma}{r_0} - 1 = \frac{(r-r_0)(1-\frac{b}{q})}{b-(r-r_0)-\frac{r_0 b}{q}}, \quad B = 2^{4\left(\frac{r-r_0}{r_0} + \frac{\gamma}{r_0}\right)}, \quad C = \frac{1}{k^{\gamma} \frac{r_0}{q}}.
\]

Notice that \( \delta \) is a positive constant being, by assumption, \( r > r_0 \) and \( b_0 < b < q \).
Since (3.24) is obtained applying the integral inequality (3.4) and now such estimate is true only for \( k \geq \sigma_0 \), we need to require that \( k_m \geq \sigma_0 \) for every \( m \in \mathbb{N} \cup \{0\} \) and hence, being \( k_0 = \frac{k}{2} = \min\{k_m\} \), this is true if \( k \geq 2\sigma_0 \). To conclude the proof, we
need to show that also the assumption (3.19) of Lemma 3.1 is satisfied, i.e., that it results
\[ Y_0 \leq C^{-\frac{1}{\beta}} B^{-\frac{1}{\beta^2}}. \] (3.25)

Now proceeding exactly as that of Theorem 2.1 in [42] but with the further requirement that \( k \) has to be chosen satisfying also the inequality \( k \geq 2\sigma_0 \) we obtain
\[
\|u(t)\|_{L^\infty(\Omega)} \leq \max \left\{ 2\sigma_0, C_1 \frac{\|u_0\|_{L^0(\Omega)}}{t^{\beta_1}} \right\} \quad \text{for every} \quad t \in (0, T)
\]
from which the assertion follows. \( \square \)

**Proof of Theorem 3.4.** Analogously to the proof of the previous theorem, it is sufficient to proceed exactly as in the proof of Theorem 2.2 (case \( b = r \)) in [42] (recalled above as Theorem 3.2) but with the further requirement that \( k \) has to be chosen satisfying also the inequality \( k \geq 2\sigma_0 \). This restriction on \( k \) implies that the following estimate holds true (instead of (3.9))
\[
\|u(t)\|_{L^\infty(\Omega)} \leq \max \left\{ 2\sigma_0, C_2 \frac{\|u_0\|_{L^0(\Omega)}}{e^{\sigma_1 t} t^{\beta_1}} \right\} \quad \text{for every} \quad t \in (0, T)
\]
where \( C_2, \sigma \) and \( h_1 \) are as in Theorem 3.2. From the last inequality, the assertion follows. \( \square \)

**Proof of Theorem 3.5.** Analogously to the proof of the previous theorem, it is sufficient to proceed exactly as in the proof of Theorem 2.2 (case \( b > r \)) in [42] but once again with the further requirement that \( k \) has to be chosen satisfying also the inequality \( k \geq 2\sigma_0 \). This restriction on \( k \) implies that the following estimate holds true (instead of (3.12))
\[
\|u(t)\|_{L^\infty(\Omega)} \leq \max \left\{ 2\sigma_0, \frac{C_\sharp}{t^{\beta_2}} \right\} \quad \text{for every} \quad t \in (0, T)
\]
where \( C_\sharp \) and \( h_2 \) are as in Theorem 3.2. From the last inequality, the assertion follows. \( \square \)

### 4. Proofs

**Proof of Theorem 2.1.** Let \( u \) be the solution constructed as the a.e. limit in \( \Omega_T \) of the solutions \( u_n \in L^\infty(\Omega_T) \cap L^p(0, T; W^{1,p}_0(\Omega)) \) to the following approximating problems
\[
\begin{cases}
(u_n)_t - \div(a(x, t, u_n, \nabla u_n)) + \alpha_0 u_n = f(x, t) \quad \text{in} \quad \Omega_T, \\
u_n = 0 \quad \text{on} \quad \Gamma, \\
u_n(x, 0) = u_{0,n}(x) \quad \text{on} \quad \Omega,
\end{cases}
\] (4.1)
where the data \( u_{0,n}(x) \in C^\infty_c(\Omega) \) satisfy
\[
\|u_{0,n}(x)\|_{L^0(\Omega)} \to u_0 \quad \text{in} \quad L^{r_0}(\Omega), \quad \|u_{0,n}(x)\|_{L^r(\Omega)} \leq \|u_0(x)\|_{L^r(\Omega)}.
\] (4.2)
(see for example [7,8,44]).

The proof proceeds in two steps. Firstly, we prove estimates (2.4) and (2.7) and then we show that also estimates (2.6) and (2.8) hold true.

**Step 1.** To prove estimate (2.4), it is sufficient to demonstrate that the following inequality holds
\[
\|u_n(t)\|_{L^\infty(\Omega)} \leq A(t)
\] (4.3)
where \( A(t) \) is as in (2.4). Let \( \varepsilon \) and \( k \) be positive constants arbitrarily fixed and take \( \phi = \{[\varepsilon + (|u_n|-k)_+]r^{-1} - \varepsilon r^{-1}\} \sign (u_n) \) as test function in (4.1) where \( r > r_0 \) (hence \( r > 1 \)) is arbitrarily fixed too. Notice that the use of such a test function, together with the following ones, can be made rigorous by means of Steklov averaging process.

Using assumption (1.2), we obtain for every \( 0 \leq t_1 < t_2 \leq T \)
\[
\begin{align*}
\int_\Omega \Psi(u_n(t_2))dx &- \int_\Omega \Psi(u_n(t_1))dx \\
+ c_1 &\int_{t_1}^{t_2} \int_\Omega \left| \nabla \left[ (\varepsilon + |G_k(u_n(x,t))|)^{\frac{r-2+p}{p}} - \varepsilon^{\frac{r-2+p}{p}} \right] \sign (u_n) \right|^p dx \, dt \\
+ c_2 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{r-1} - \varepsilon^{r-1} \|_{L^p(\Omega)} \, dr \\
+ c_3 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{r-1} - \varepsilon^{r-1} \|_{L^p(\Omega_T)} \, dt \\
\leq c_1, c_2, c_3
\end{align*}
\]
where \( G_k \) is the function defined in (3.1) and
\[
\psi(s) = \int_0^s \left[ (\varepsilon + (|\sigma| - k)_+)^{r-1} - \varepsilon^{r-1} \right] \sign (\sigma) \, d\sigma.
\]
Applying Sobolev inequality in the previous estimate, we deduce
\[
\begin{align*}
\int_\Omega \Psi(u_n(t_2))dx &- \int_\Omega \Psi(u_n(t_1))dx \\
+ c_1 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{\frac{r-2+p}{p}} - \varepsilon^{\frac{r-2+p}{p}} \|_{L^p(\Omega)} \, dr \\
+ c_2 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{r-1} - \varepsilon^{r-1} \|_{L^p(\Omega_T)} \, dt \\
\leq c_1, c_2, c_3
\end{align*}
\]
Applying Sobolev inequality in the previous estimate, we deduce
\[
\begin{align*}
\int_\Omega \Psi(u_n(t_2))dx &- \int_\Omega \Psi(u_n(t_1))dx \\
+ c_1 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{\frac{r-2+p}{p}} - \varepsilon^{\frac{r-2+p}{p}} \|_{L^p(\Omega)} \, dr \\
+ c_2 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{r-1} - \varepsilon^{r-1} \|_{L^p(\Omega_T)} \, dt \\
\leq c_1, c_2, c_3
\end{align*}
\]
Applying Sobolev inequality in the previous estimate, we deduce
\[
\begin{align*}
\int_\Omega \Psi(u_n(t_2))dx &- \int_\Omega \Psi(u_n(t_1))dx \\
+ c_1 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{\frac{r-2+p}{p}} - \varepsilon^{\frac{r-2+p}{p}} \|_{L^p(\Omega)} \, dr \\
+ c_2 &\int_{t_1}^{t_2} \| (\varepsilon + |G_k(u_n(x,t))|)^{r-1} - \varepsilon^{r-1} \|_{L^p(\Omega_T)} \, dt \\
\leq c_1, c_2, c_3
\end{align*}
\]
where \( c_2 = c_2(p,N) \). Notice that it results \( c_S < \frac{p^*}{p} = \frac{(N-1)p}{N-p} \) see [18].

\[
\int_{\Omega} \| \nabla g \|_p^p \geq c_S \| g \|_{L^{p^*}(\Omega)}^p \quad \text{for every} \quad g \in W_0^{1,p}(\Omega),
\] (4.4)
where \( c_2 = c_1 c_S \). Notice that choosing \( k \geq \sigma_0 = \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0} \) the last integral in the previous inequality is nonnegative. Hence, letting \( \varepsilon \to 0 \) we deduce that for every \( 0 \leq t_1 < t_2 \leq T \) and \( k \geq \sigma_0 \) the following inequality holds
\[
\frac{1}{r} \int_{\Omega} |G_k(u_n(x, t_2))|^{r} \, dx - \frac{1}{r} \int_{\Omega} |G_k(u_n(x, t_1))|^{r} \, dx + c_2 \int_{t_1}^{t_2} \|G_k(u_n(t))\|^{\frac{r-2+p}{p}}_{L^p(\Omega)} \, dt \leq 0,
\]
that is
\[
\int_{\Omega} |G_k(u_n(x, t_2))|^{r} \, dx - \int_{\Omega} |G_k(u_n(x, t_1))|^{r} \, dx + c_3 \int_{t_1}^{t_2} \|G_k(u_n(t))\|_{L^q(\Omega)}^{b} \, dt \leq 0
\]
(4.5)
where we have denoted
\[
c_3 = c_2 r, \quad b = r - 2 + p, \quad q = \frac{N(r - 2 + p)}{N - p}.
\]
(4.6)
We recall that we have chosen \( r > r_0 \). Moreover, since it results
\[
q > r \iff p > \frac{2N}{N + r}
\]
the previous inequality is satisfied since we have assumed \( p > \frac{2N}{N + r_0} \). Furthermore, we have
\[
b > b_0 = \frac{r - r_0}{1 - \frac{r_0}{q}} \iff p > \frac{2N}{N + r_0}
\]
that is, again true by our assumption on \( p \). Thus, the previous choice of \( b, r \) and \( q \) satisfy (3.3). Observe that if \( r_0 > 1 \), proceeding as above but with \( r = r_0 \) we deduce that (4.5) holds true also with \( r = r_0 \), and thus the following estimate follows
\[
\int_{\Omega} |G_k(u_n(x, t_2))|^{r_0} \, dx \leq \int_{\Omega} |G_k(u_n(x, t_1))|^{r_0} \, dx \quad \text{for every} \quad 0 \leq t_1 < t_2 < T,
\]
(4.7)
and hence (3.5) is satisfied. Otherwise, if \( r_0 = 1 \), taking \( \varphi = \left\{ 1 - \frac{1}{[1 + |G_k(u_n)|]^{\delta}} \right\} \) sign\( (u_n) \) (\( \delta > 1 \)) as test function we get
\[
\int_{\Omega} |G_k(u_n)|^{(t)} + \frac{1}{1 - \delta} \int_{\Omega} \left\{ 1 - \frac{1}{[1 + |G_k(u_n)|]^{\delta - 1}} \right\} \\
+ \delta \int_{t_0}^{t} \int_{\Omega} a(x, t, u_n, \nabla u_n) \nabla G_k(u_n) \frac{1}{[1 + |G_k(u_n)|]^{\delta + 1}} \\
+ \alpha_0 \int_{t_0}^{t} \int_{\Omega} \left| u_n \right| - \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0} \left\{ 1 - \frac{1}{[1 + |G_k(u_n)|]^{\delta}} \right\} \\
\leq \int_{\Omega} |G_k(u_n)|(t_0) + \frac{1}{1 - \delta} \int_{\Omega} \left\{ 1 - \frac{1}{[1 + |G_k(u_n)|(t_0)]^{\delta - 1}} \right\},
\]
from which choosing again $k \geq \sigma_0 = \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0}$ and using (1.2) (and that $\delta > 1$) we obtain for every $0 \leq t_0 < t < T$

$$\int_{\Omega} |G_k(u_n)|(t) \leq \int_{\Omega} |G_k(u_n)|(t_0) + \frac{1}{\delta - 1} \int_{\Omega} \frac{1}{[1 + |G_k(u_n)|(t_0)]^{\delta - 1}},$$

from which (letting $\delta \to +\infty$) we deduce for every $0 \leq t_0 < t < T$ and $k \geq \sigma_0$

$$\int_{\Omega} |G_k(u_n)|(t) \leq \int_{\Omega} |G_k(u_n)|(t_0),$$

which is inequality (3.5) with $r_0 = 1 = c_2$.

Thus, applying Theorem 3.4 if $p = 2$ and Theorem 3.3 if otherwise $p \neq 2$ and recalling the construction (4.2), we deduce that estimate (4.3) holds true.

Notice that if $p > 2$ it results $b > r$. Hence, applying Theorem 3.5 and noticing that $b - r = p - 2$ it follows that

$$\|u_n(t)\|_{L^\infty(\Omega)} \leq c(N, \alpha, r_0, p, |\Omega|) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\alpha_0}, \frac{1}{t^{\frac{1}{p-2}}} \right\},$$

which implies the bound (2.7).

**Step 2.** As said above, we prove here that also estimates (2.6) and (2.8) hold. To this aim, taking $u_n$ as test function in the approximating problem (4.1) we obtain for every $0 < t \leq T$

$$\frac{1}{2} \int_{\Omega} |u_n(T)|^2 + \alpha \int_{t}^{T} \int_{\Omega} |\nabla u_n|^p + \alpha_0 \int_{t}^{T} \int_{\Omega} u_n^2 \leq \frac{1}{2} \int_{\Omega} |u_n(t)|^2 + \int_{t}^{T} \int_{\Omega} f u_n.$$  

We estimate now the right-hand side of the previous inequality. By (4.3), it follows

$$\frac{1}{2} \int_{\Omega} |u_n(t)|^2 \leq \frac{|\Omega|}{2} [A(t)]^2.$$  

Moreover, we have

$$\int_{t}^{T} \int_{\Omega} f u_n \leq \|u_n\|_{L^\infty(\Omega \times (t, T))} \|f\|_{L^1(\Omega_T)}.$$  

Notice that again by (4.3) it results

$$\|u_n\|_{L^\infty(\Omega \times (t, T))} \leq \sup_{\tau \in (t, T)} \|u_n(\tau)\|_{L^\infty(\Omega)} \leq \sup_{\tau \in (t, T)} A(\tau) = A(t).$$  

Hence, by the previous two inequalities we deduce

$$\int_{t}^{T} \int_{\Omega} f u_n \leq A(t) \|f\|_{L^1(\Omega_T)}.$$  

(4.12)
By (4.10)–(4.12), we conclude that
\[ \int_t^T \int_\Omega |\nabla u_n|^p \leq \frac{1}{\alpha} A(t) \left( |\Omega| \frac{1}{2} A(t) + \| f \|_{L^1(\Omega_T)} \right), \tag{4.13} \]
from which the assertion (2.6) follows.

Finally, if \( p > 2 \), proceeding exactly as above but using (4.9) instead of (4.3) and hence replacing \( A(t) \) with \( U(t) \) (see (2.7)) we deduce that also the following estimate holds true
\[ \int_t^T \int_\Omega |\nabla u_n|^p \leq \frac{1}{\alpha} U(t) \left( |\Omega| \frac{1}{2} U(t) + \| f \|_{L^1(\Omega_T)} \right), \]
from which (2.8) follows. \( \square \)

**Proof of Theorem 2.2.** Let \( \rho > 0 \) arbitrarily fixed and consider the following nonlinear problem
\[ \left\{ \begin{array}{ll}
 v_t - \text{div}(\overline{a}(x, t, v, \nabla v)) + \rho v = \overline{f}(x, t) & \text{in } \Omega_T, \\
v = 0 & \text{on } \Gamma, \\
v(x, 0) = u_0(x) & \text{on } \Omega,
\end{array} \right. \tag{4.14} \]
where we have defined
\[ \overline{a}(x, t, s, \xi) = a(x, t, se^{\rho t}, e^{\rho t} \xi)e^{-\rho t} \quad \overline{f}(x, t) = f(x, t)e^{-\rho t}. \tag{4.15} \]

By the assumptions (1.2)–(1.5), it follows that the operator \( \overline{a} \) satisfies
\[ \overline{\alpha}|\xi|^p \leq \overline{a}(x, t, s, \xi) \xi, \quad \overline{\alpha} > 0, \quad 1 < p < N \tag{4.16} \]
\[ |\overline{a}(x, t, s, \xi)| \leq \overline{\beta} |s|^{p-1} + |\xi|^{p-1} + h(x, t), \quad \overline{\beta} > 0, \quad (4.17) \]
\[ [\overline{a}(x, t, s, \xi) - \overline{a}(x, t, s, \eta)]|\xi - \eta| > 0, \quad \xi \neq \eta. \tag{4.18} \]
where \( h \) is as in (1.4)

\[ \overline{\alpha} = \alpha e^{-\rho(2-p)+T} = \begin{cases} 
\alpha & \text{if } p \geq 2 \\
\alpha_p = \alpha e^{-\rho(2-p)T} & \text{if } p < 2
\end{cases} \tag{4.19} \]
and
\[ \overline{\beta} = \beta e^{\rho(p-2)+T} = \begin{cases} 
\beta & \text{if } p \leq 2 \\
\beta_p = \beta e^{\rho(p-2)T} & \text{if } p > 2
\end{cases} \tag{4.20} \]

Moreover, by assumption (1.7) we deduce that \( \overline{f} \) belongs to \( L^\infty(\Omega_T) \). Hence, we can apply Theorem 2.1 with \( \alpha_0 = \rho \) (see also Remark 2.2) and conclude that there exists a solution \( v \) of (4.14) belonging to \( C(\overline{\Omega} \times (0, T)) \) satisfying (for every \( t \in (0, T) \)) the following estimates
\[ \| v(t) \|_{L^\infty(\Omega)} \leq \overline{A}(t) \equiv \begin{cases} 
\left( c(N, \alpha, r_0) \max \left\{ \frac{\| \overline{f} \|_{L^\infty(\Omega_T)}}{\rho}, \frac{\| u_0 \|_{L^0(\Omega)}}{e^{\rho t_1}r_0^{1/2}} \right\} \right) & \text{if } p = 2 \\
\left( c(N, \overline{\alpha}, r_0, \rho) \max \left\{ \frac{\| \overline{f} \|_{L^\infty(\Omega_T)}}{\rho}, \frac{\| u_0 \|_{L^0(\Omega)}}{e^{\rho t_1}} \right\} \right) & \text{if } p \neq 2
\end{cases} \tag{4.21} \]
where $\alpha$ is as in (4.19), $\sigma = \frac{a c_S(r_0)}{\Omega} \frac{1}{2}$ (4.4) and the exponents $h_0$ and $h_1$ are as in (2.5). Moreover, $\nabla v \in \left[ L^p \left( \Omega \times (t, T) \right) \right]^N$ for every $t \in (0, T)$ and also the following estimate holds true

$$\int_t^T \int_\Omega |\nabla v|^p \leq \frac{1}{\alpha} \bar{A}(t) \left( \frac{|\Omega|}{2} \bar{A}(t) + \|f\|_{L^1(\Omega_T)} \right),$$

(4.22)

where $\bar{A}(t)$ is as in (4.21). Besides, if $p > 2$ also the following estimates are satisfied

$$\|v(t)\|_{L^\infty(\Omega)} \leq \bar{U}(t) \equiv c(N, \alpha, r_0, p, |\Omega|) \max \left\{ \frac{\|f\|_{L^\infty(\Omega_T)}}{\rho}, \frac{1}{t^{\frac{1}{p-2}}} \right\},$$

(4.23)

$$\int_t^T \int_\Omega |\nabla v|^p \leq \frac{1}{\alpha} \bar{U}(t) \left( \frac{|\Omega|}{2} \bar{U}(t) + \|f\|_{L^1(\Omega_T)} \right),$$

(4.24)

Notice that the function $u = ve^{\rho t}$ is a solution of (1.1). Hence, we can rewrite (4.21)–(4.24) as

$$\|ue^{-\rho t}\|_{L^\infty(\Omega)} \leq \bar{A}(t)$$

(4.25)

$$\int_t^T \int_\Omega |\nabla ue^{-\rho t}|^p \leq \frac{1}{\alpha} \bar{A}(t) \left( \frac{|\Omega|}{2} \bar{A}(t) + \|f\|_{L^1(\Omega_T)} \right),$$

(4.26)

$$\|ue^{-\rho t}\|_{L^\infty(\Omega)} \leq \bar{U}(t) \quad \text{if} \quad p > 2$$

(4.27)

$$\int_t^T \int_\Omega |\nabla ue^{-\rho t}|^p \leq \frac{1}{\alpha} \bar{U}(t) \left( \frac{|\Omega|}{2} \bar{U}(t) + \|f\|_{L^1(\Omega_T)} \right), \quad \text{if} \quad p > 2.$$ (4.28)

Now estimates (2.10) follow by (4.25) while estimate (4.27) implies estimate (2.13). Notice since it results

$$\|f\|_{L^1(\Omega_T)} \leq \|f\|_{L^1(\Omega_T)}$$

and

$$\int_t^T \int_\Omega |\nabla u|^p \geq e^{-ppT} \int_t^T \int_\Omega |\nabla u|^p.$$}

by estimates (4.26) and (4.28) it is possible to derive the following estimates for $\nabla u$ in $L^p(\Omega \times (t, T))$

$$\int_t^T \int_\Omega |\nabla u|^p \leq \frac{e^{\max(2, p)\rho T}}{\alpha} B(t) \left( \frac{|\Omega|}{2} B(t) + \|f\|_{L^1(\Omega_T)} \right),$$

(4.29)

and if $p > 2$

$$\int_t^T \int_\Omega |\nabla u|^p \leq \frac{e^{ppT}}{\alpha} B_0(t) \left( \frac{|\Omega|}{2} B_0(t) + \|f\|_{L^1(\Omega_T)} \right),$$

(4.30)

where $B(t)$ and $B_0$ are as in the statement of the theorem.
Indeed, once we know that estimates (2.10) and (2.13) are satisfied it is possible to derive a slightly better estimate on $\nabla u$, respect to estimates (4.29) and (4.30) obtained above, using directly the equation satisfied by $u$ instead of the estimates of $\nabla v$. As a matter of fact, it results (recalling the construction of $u$) for every $0 < t < T$

$$
\frac{1}{2} \int_{\Omega} |u(T)|^2 + \alpha \int_t^T \int_{\Omega} |\nabla u|^p \leq \frac{1}{2} \int_{\Omega} |u(t)|^2 + \int_t^T \int_{\Omega} fu,
$$

which implies

$$
\int_t^T \int_{\Omega} |\nabla u|^p \leq \frac{\Omega}{2\alpha} \|u(t)\|^2_{L^\infty(\Omega)} + \frac{1}{\alpha} \|u\|_{L^\infty(\Omega \times (t, T))} \|f\|_{L^1(\Omega_T)}.
$$

Now, estimate (2.12) is an immediate consequence of estimates (4.32) and (2.10) while (2.14) follows by (4.32) and (2.13).

**Proof of Theorem 2.3.** As in the proof of the previous theorem, we consider an auxiliary problem. In detail, let $\rho > \alpha_0$ and let us consider the following problem

$$
\begin{cases}
   v_t - \text{div}(\overline{a}(x, t, v, \nabla v)) + (\rho - \alpha_0)v = \overline{f}(x, t) \quad &\text{in} \quad \Omega_T, \\
   v = 0 \quad &\text{on} \quad \Gamma, \\
   v(x, 0) = u_0(x) \quad &\text{on} \quad \Omega,
\end{cases}
$$

where $\overline{a}$ and $\overline{f}$ are as in (4.15). Now it is sufficient to proceed exactly as in the proof of Theorem 2.2 to get the result with the only difference that in applying Theorem 2.1 the absorption term is now $(\rho - \alpha_0)v$ instead $\rho v$. Notice that this change in the absorption term is the reason of the slow differences in the bounds satisfied by the solution $u$ of (2.20) respect to the bounds satisfied by the solution described in Theorem 2.2 (i.e., the when $\alpha_0 = 0$). \qed

**Remark 4.1.** We notice that the estimates of the previous theorems hold true also replacing assumption (1.4) on $h$ with the weaker hypothesis $h \in L^p(\Omega_T)$.

**Proof of Theorem 2.4.** The proof proceeds in two steps. Firstly, we prove the existence of a global solution $u$ when $f \in L^1_{\text{loc}}([0, +\infty); L^1(\Omega))$ and the regularity $C_{\text{loc}}([0, +\infty); L^1(\Omega))$ when the operator $a$ is independent of $u$. Then, in Step 2, we show the further regularity properties of $u$ when $p > \frac{2N}{N+r_0}$.

**Step 1.** Let us consider the following approximating problems

$$
\begin{cases}
   (u_n)_t - \text{div}(a(x, t, u_n, \nabla u_n)) + \alpha_0 u_n = f_n(x, t) \quad &\text{in} \quad \Omega \times (0, +\infty), \\
   u_n = 0 \quad &\text{on} \quad \partial \Omega \times (0, +\infty), \\
   u_n(x, 0) = u_{0,n}(x) \quad &\text{on} \quad \Omega,
\end{cases}
$$

where

$$
\begin{align*}
   u_{0,n} &\in C^\infty_c(\Omega) : \quad u_{0,n} \rightharpoonup u_0 \quad \text{in} \quad L^1(\Omega)
\end{align*}
$$

(4.35)
and \( f_n(x, t) \in L^\infty_{loc}([0, +\infty); L^\infty(\Omega)) \) satisfy

\[
\text{for every } T > 0 : \quad f_n(x, t) \to f(x, t) \quad \text{in } L^1(\Omega_T). \tag{4.36}
\]

We recall that for every fixed \( n \in \mathbb{N}, \) there exists a unique global solution \( u_n \) of (4.34) in \( L^\infty_{loc}([0, +\infty); L^\infty(\Omega)) \cap C_{loc}([0, +\infty); L^2(\Omega)) \cap L^p_{loc}([0, +\infty); W^{1, p}_0(\Omega)). \) Moreover, for every arbitrarily fixed \( T > 0, \) there exists a subsequence of the sequence \( u_n \) converging a.e. in \( \Omega_T \) (indeed a stronger convergence holds) to a solution of our problem (1.1) in \( \Omega_T \) (see for example [6–9, 44, 52]).

Using the above properties of the sequence \( u_n \) we construct now a global solution \( u \) of (1.1). To this aim, let \( T_0 \) be a positive constant arbitrarily fixed. As said above, there exists a subsequence \( u^{(1)}_n \) of \( u_n \) satisfying

\[
u^{(1)}_n \to u_1 \quad \text{a.e. in } \Omega_{T_0}
\]

where \( u_1 \) is a solution of (1.1) in \( \Omega_{T_0}. \) We know that every term of the sequence \( u^{(1)}_n \) is a global solution, and therefore it is also a solution in \( \Omega_{2T_0}. \) Hence, for what recalled above, there exists a subsequence \( u^{(2)}_n \) of \( u^{(1)}_n \) satisfying

\[
u^{(2)}_n \to u_2 \quad \text{a.e. in } \Omega_{2T_0}
\]

where \( u_2 \) is a solution of (1.1) in \( \Omega_{2T_0}. \)

Iterating this procedure, we can define \( u \) (in all the set \( \Omega \times (0, +\infty) \)) in the following way

\[
\text{for every } T > 0 : u(x, t) = u_h(x, t) \quad \text{a.e. in } \Omega_T,
\]

where \( h \in \mathbb{N} \) is such that \( hT_0 > T. \) We point out that \( u \) is well defined since (by construction) if \( m \in \mathbb{N} \) is such that \( mT_0 > T \) then it results

\[
u_h(x, t) = u_m(x, t) \quad \text{a.e. in } \Omega_T.
\]

We point out that \( u \) is a global solution of (1.1) since (by construction) for every arbitrarily fixed \( T > 0 \) \( u \) solves (1.1).

To conclude this step, it remains to show that if \( a(x, t, s, \xi) \equiv a(x, t, \xi) \) then \( u \) belongs to \( C_{loc}([0, +\infty); L^1(\Omega)). \) Notice that it is sufficient to show that for every \( T > 0 \) arbitrarily fixed the sequence \( u_n \) is a Cauchy sequence in \( C([0, T]; L^1(\Omega)). \)

The proof of this last fact is similar at all to that in [52] (see also [49]) and hence we omit it.

**Step 2.** Assume \( p > \frac{2N}{N+2p_0}. \) We distinguish two cases: the “more regular case” (case 1) with stronger assumptions on \( f \) and \( \alpha_0 > 0 \) and the “less regular case” (case 2) with a weaker assumption on \( f \) and \( \alpha_0 \geq 0. \)

**Case 1:** Let \( f \) be in \( L^\infty(\Omega_\infty) \cap L^1(\Omega_\infty) \) and \( \alpha_0 > 0. \) Let \( u \) be the solution constructed in the previous step. Thanks to the further assumptions, we have done here we can choose in the above approximating problems (4.34)

\[
f_n(x, t) \equiv f(x, t) \tag{4.37}
\]
and \(u_{0,n}(x)\) satisfying

\[
    u_{0,n}(x) \to u_0 \quad \text{in } L^{r_0}(\Omega), \quad \|u_{0,n}(x)\|_{L^{r_0}(\Omega)} \leq \|u_0(x)\|_{L^{r_0}(\Omega)}.
\]

(4.38)

Thanks to the above construction of \(u\) and recalling the assumption \(\alpha_0 > 0\), for every \(T > 0\) arbitrarily fixed we can proceed exactly as in the proof of Theorem 2.1 obtaining that \(u\) satisfies estimates (2.4) and (2.6) for every \(T > 0\) arbitrarily fixed. Consequently, for every \(t_0 > 0\) it follows

\[
    \|u\|_{L^{\infty}(\Omega \cap [t_0, +\infty))} \leq A^{\infty}(t_0) \equiv \begin{cases} 
    c(N, \alpha, r_0) \max \left\{ \frac{\|f\|_{L^{\infty}(\Omega)}}{\alpha_0}, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{e^{\alpha_0 t_0}} \right\} & \text{if } p = 2 \\
    c(N, \alpha, r_0, p) \max \left\{ \frac{\|f\|_{L^{\infty}(\Omega)}}{\alpha_0}, \frac{\|u_0\|_{L^{r_0}(\Omega)}}{t_0} \right\} & \text{if } p \neq 2
    \end{cases}
\]

(4.39)

and

\[
    \int_{t_0}^{+\infty} \int_{\Omega} |\nabla u|^p \leq \frac{1}{\alpha} A^{\infty}(t_0) \left( \frac{|\Omega|}{2} A^{\infty}(t_0) + \|f\|_{L^1(\Omega)} \right),
\]

(4.40)

where \(\alpha\) is as in (1.2), \(c_S = c_S(N)\) is the Sobolev constant defined in (4.4) and \(\sigma, h_0\) and \(h_1\) are as in (2.4).

Hence, \(u\) belongs to \(L^{\infty}(\Omega \times [t_0, +\infty)) \cap L^p(t_0, +\infty; W_0^1, p(\Omega))\) for every arbitrarily fixed \(t_0 > 0\). To conclude the proof, it remains to show that \(u\) belongs also to \(C([t_0, +\infty); L^r(\Omega))\) for every \(r \geq 1\) arbitrarily chosen. To this aim, we observe that by the structure assumption (1.3), the regularity assumed on \(f\) and the above regularity proved on \(u\) imply that \(u\) belongs also to \(C([t_0, +\infty); L^2(\Omega))\). Hence, by the classical theory (see [22, 33]) we obtain that \(u\) is in \(C(\bar{\Omega} \times [t_0, +\infty))\). Thus, it follows that \(u\) belongs also to \(C([t_0, +\infty); L^r(\Omega))\) for every \(r \geq 1\).

**Case 2:** Let \(f\) be in \(L^{\infty}_{loc}([0, +\infty); L^{\infty}(\Omega))\) and \(\alpha_0 \geq 0\). Thanks to the further regularity assumption on \(f\), we have done here we can choose in the approximating problems (4.34) \(f_n\) and \(u_{0,n}(x)\) as in the previous case, i.e., satisfying (4.37) and (4.38). Thanks to the above construction of \(u\) and recalling the assumption on \(p\) done in this step, for every \(T > 0\) arbitrarily fixed we can proceed exactly as in the proof of Theorem 2.2 obtaining that \(u\) satisfies estimates (2.10) and (2.12) for every \(T > 0\) arbitrarily fixed. Thus, \(u\) belongs to \(L^{\infty}_{loc}((0, +\infty); L^{\infty}(\Omega)) \cap L^p_{loc}((0, +\infty); W_0^1, p(\Omega))\). Now the remaining regularity \(C_{loc}((0, +\infty); L^r(\Omega))\) can be proved reasoning as in Case 1 and hence we omit it.

**Proof of Theorem 2.5.** The assertion follows by the following more general result.

**Theorem 4.1.** Let (1.2)–(1.4) hold true with \(T = +\infty\) and \(\alpha_0 > 0\). Assume that \(u\) and \(v\) are two global solutions of (1.1) relative to the same datum \(f \in L^1_{loc}(0, +\infty; L^1(\Omega))\)
and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) \((r_0 \geq 1)\). If \( u \) and \( v \) belong to \( L^p_{loc}(\Omega) \) \( \cap \) \( L^{\infty}_{loc}(\Omega) \) \( \cap \) \( C_{loc}(\Omega) \) for an arbitrarily fixed \( t_0 > 0 \) and \( r \in [2, +\infty) \), then for every \( t_0 < t < T_0 < +\infty \) it results

\[
\int_{\Omega} |u - v|^r(t) \leq \Lambda_0 e^{-\alpha_0(r(t-t_0))} + \int_{t_0}^t g(s)ds, \tag{4.41}
\]

where \( \Lambda_0 = \int_{\Omega} |u - v|^r(t_0) \) and \( g(s) \equiv r(r-1)c_1 \int_{\Omega} |\nabla u|^p + |\nabla v|^p + |h|^p \) with \( c_1 = c(\beta, p, \Omega, N) \|u - v\|_{L^\infty(\Omega \times [t_0, t_0])}^2 \).

Moreover, if in addition we assume that \( u \) and \( v \) belong to \( L^\infty(\Omega \times (t_1, +\infty)) \) for some \( t_1 \geq t_0 \), then for every \( t > t_2 \geq t_1 \) arbitrarily fixed it results

\[
\int_{\Omega} |u - v|^r(t) \leq \Lambda_1 e^{-\alpha_0(r(t-t_2))} + \int_{t_2}^t g_1(s)ds, \tag{4.42}
\]

where \( \Lambda_1 = \|u - v\|_{L^\infty(\Omega \times (t_1, +\infty))}^2 \), \( g_1(s) \equiv r(r-1)c_1 \int_{\Omega} |\nabla u|^p + |\nabla v|^p + |h|^p \) and \( c_1 = c(\beta, p, \Omega, N) \|u - v\|_{L^\infty(\Omega \times (t_1, +\infty))}^2 \).

In particular, if it results

\[
\lim_{t \to +\infty} \int_{t_2}^t g(s)ds = 0 \tag{4.43}
\]

(for example if \( u \) and \( v \) belong to \( L^p(t_1, +\infty; W^{1,p}_0(\Omega)) \) and \( h \in L^{p'}(\Omega \times [t_1, +\infty)) \)) then it follows

\[
\lim_{t \to +\infty} \|u(t) - v(t)\|_{L^{r'}(\Omega)} = 0. \tag{4.44}
\]

**Remark 4.2.** As already noticed in Remark 2.6, under the structure assumptions of Theorem 2.5 if \( p > \frac{2N}{N+r_0} \) and \( f \) belongs also to \( L^\infty(\Omega \times (0, +\infty)) \) there exists at least a global solution of (1.1) belonging to \( L^\infty(\Omega \times (0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \cap C([t_0, +\infty); L^2(\Omega)) \) for every arbitrarily fixed \( t_0 > 0 \). As a matter of fact, thanks to Theorem 2.1 (see also Remark 2.2) it is possible to extend the solution \( u \) constructed in Theorem 2.1 in a solution of (2.26) that for sake of simplicity we denote again with \( u \). Again by Theorem 2.1 (and thanks to the assumption that \( f \in L^\infty(\Omega \times (0, +\infty)) \cap L^1(\Omega \times (0, +\infty)) \)) it follows that \( u \) belongs to \( L^\infty(\Omega \times (t_0, +\infty)) \cap L^p(t_0, +\infty; W^{1,p}_0(\Omega)) \cap C([t_0, +\infty); L^2(\Omega)) \) for every arbitrarily fixed \( t_0 > 0 \).

**Proof of Theorem 4.1.** We start proving (4.41). Hence, let \( T_0 > 0 \) be arbitrarily fixed. Choosing \( |u - v|^{r-2}(u - v) \) as a test function in both the equations satisfied by \( u \) and \( v \) we deduce for every \( t_0 \leq t_1 < t_2 \leq T_0 \)

\[
\int_{\Omega} \frac{1}{r} |u - v|^r(t_2) - \frac{1}{r} |u - v|^r(t_1) + (r-1) \int_{t_1}^{t_2} \int_{\Omega} [a(x, t, u, \nabla u) - a(x, t, v, \nabla v)]\nabla|u - v|^{r-2} + \alpha_0 \int_{t_1}^{t_2} \int_{\Omega} |u - v|^r \leq 0. \tag{4.45}
\]
It results (by (1.3), Young and Poincare inequality\(^4\))

\[
\int_{t_1}^{t_2} \int_{\Omega} \left| a(x, t, u, \nabla u) - a(x, t, v, \nabla v) \right| \nabla (u - v) |u - v|^{-2} \, dx \, dt \\
\leq c(\beta, p) \int_{t_1}^{t_2} \int_{\Omega} \left[ |u|^p + |\nabla u|^p + |v|^p + |\nabla v|^p + |h|^p \right] \|u - v\|^p_{L^\infty(\Omega \times [t_0, T_0])} \\
\leq c_1 \int_{t_1}^{t_2} \int_{\Omega} \left[ |\nabla u|^p + |\nabla v|^p + |h|^p \right] 
\] (4.47)

where \( c_1 = c(\beta, p, \Omega, N)[\|u - v\|_{L^\infty(\Omega \times [t_0, T_0])}]^{-2} \). By (4.45) and (4.47), it follows that

\[
\int_{\Omega} |u - v|^p (t_2) - \int_{\Omega} |u - v|^p (t_1) + \alpha_0 r \int_{t_1}^{t_2} \int_{\Omega} |u - v|^p \leq \int_{t_1}^{t_2} g(t) \, dt
\]

where \( g(t) \equiv r(r - 1)c_1 \int_{\Omega} \left[ |\nabla u|^p + |\nabla v|^p + |h|^p \right] \).

Notice that \( g(t) \) belongs to \( L^1(t_0, T_0) \). Hence, applying Theorem 3.7 with \( \Psi(t) = \int_{\Omega} |u - v|^p (t) \) we deduce that the following estimate holds for every \( t_0 \leq t < T_0 \)

\[
\int_{\Omega} |u - v|^p (t) \leq \Lambda_0 e^{-\alpha_0 r(t - t_0)} + \int_{t_0}^t g(s) \, ds,
\] (4.48)

where \( \Lambda_0 = \int_{\Omega} |u - v|^p (t_0) \). Moreover, if in addition we assume that \( u \) and \( v \) belong to \( L^\infty(\Omega \times [t_1, +\infty)) \) for some \( t_1 \geq t_0 \), then by the previous estimate we deduce that also (4.42) holds true.

We observe that if we do not know if the solutions \( u \) and \( v \) are locally bounded, it is possible to prove that estimate (4.41) still holds for \( r = 2 \). In detail, we have the following result.

**Theorem 4.2.** Let (1.2)-(1.4) hold true with \( T = +\infty \) and \( \alpha_0 > 0 \). Assume that \( u \) and \( v \) are two global solutions of (1.1) relative to the same datum \( f \) and to initial data, respectively, \( u_0 \) and \( v_0 \), where \( u_0 \) and \( v_0 \) are functions in \( L^{r_0}(\Omega) \) (\( r_0 \geq 1 \)). If \( u \) and \( v \) belong to \( L^p_{loc}(\{t_0, +\infty\}; W^{1,p}_0(\Omega)) \cap L^\infty_{loc}(\{t_0, +\infty\}; L^2(\Omega)) \) (for an arbitrarily fixed \( t_0 > 0 \)) and if \( f \) is in \( L^p_{loc}(\{t_0, +\infty\}; W^{-1,p}(\Omega)) \) then \( u \) and \( v \) belong to \( C_{loc}(\{t_0, +\infty\}; L^2(\Omega)) \) and for every \( t > t_0 \) it results

\[
\int_{\Omega} |u - v|^2 (t) \leq \Lambda_0 e^{-2\alpha_0 (t - t_0)} + \int_{t_0}^t g(s) \, ds,
\] (4.49)

\(^4\)Poincare inequality: if \( \Omega \) is an open bounded set it results

\[
\int_{\Omega} |g|^p \, dx \leq c_p \int_{\Omega} |\nabla g|^p \, dx \quad \text{for every} \quad g \in W^{1,p}_0(\Omega),
\] (4.46)

where \( c_p = c_p(p, N, \Omega) \).
where \( \Lambda_0 = \int_\Omega |u - v|^2(t_0) \) and \( g(s) \equiv 2c_1 \int_\Omega [|\nabla u|^p + |\nabla v|^p + |h|^{p'}] \) with \( c_1 = c(\beta, p, \Omega, N) \).

Moreover, if in addition we assume that \( u \) and \( v \) belong to \( L^\infty(t_1, +\infty; L^2(\Omega)) \) for some \( t_1 \geq t_0 \), then for every \( t > t_2 \geq t_1 \) arbitrarily fixed it results

\[
\int_\Omega |u - v|^2(t) \leq \Lambda_3 e^{-2\alpha_0(t-t_2)} + \int_{t_2}^t g(s) ds,
\]

where

\[
\Lambda_3 = \|u - v\|^2_{L^\infty(t_1, +\infty; L^2(\Omega))} |\Omega|
\]

In particular, if it results

\[
\lim_{t \to +\infty} \int_{t_2}^t g(s) ds = 0
\]

it follows

\[
\lim_{t \to +\infty} \|u(t) - v(t)\|_{L^2(\Omega)} = 0.
\]

**Proof of Theorem 4.2.** We observe that by the structure assumption (1.3) and by the regularity assumption done on \( u, v \) and \( f \) it follows that \( u \) and \( v \) belong to \( C_{loc}([t_0, +\infty); L^2(\Omega)) \). Now the assertions of the theorem follow choosing \( r = 2 \) and proceeding exactly as in the proof of Theorem 4.1. \( \Box \)

**Proof of Corollary 2.1.** The proof that both the solutions \( u \) and \( v \) belong to \( C([t_0, +\infty); L^r(\Omega)) \) for every \( r \geq 1 \) is at all similar to that in the proof of Theorem 2.4. In detail, by the structure assumptions and the regularity assumed on \( u, v \) and \( f \) it follows that the solutions \( u \) and \( v \) belong to \( C([t_0, +\infty); L^2(\Omega)) \) and hence, by the classical theory (see [22, 33]) they are also in \( C(\bar{\Omega} \times [t_0, +\infty)) \). Thus, the regularity \( C([t_0, +\infty); L^r(\Omega)) \) (for every \( r \geq 1 \)) follows and consequently estimate (2.28) holds true by Theorem 2.5 for every \( r \geq 2 \) (and hence for every \( r \geq 1 \)). \( \Box \)

**Proof of Theorem 2.6.** The assertion follows by Theorem 4.2. \( \Box \)

**Proof of Theorem 2.7.** Reasoning as in the proof of Corollary 2.1, it follows that \( u \) and \( v \) belong to \( C(\bar{\Omega} \times [t_0, +\infty)) \cap C_{loc}([t_0, +\infty); L^r(\Omega)) \) for every \( r \geq 2 \).

Let \( r \in [2, +\infty) \) arbitrarily fixed. Proceeding as in the proof of Theorem 2.5, we deduce that estimate (4.45) holds true for every \( t_0 \leq t_1 < t_2 \leq T_0 \), where \( T_0 > t_0 \) is arbitrarily fixed. Since the operator \( a \) does not depend on \( u \) (i.e., \( a(x, t, s, \xi) = a(x, t, \xi) \)) by the structural assumption (1.5) and by (4.45), we obtain for every \( t_0 \leq t_1 < t_2 \leq T_0 \)

\[
\int_\Omega |u - v|^r(t_2) - \int_\Omega |u - v|^r(t_1) + \alpha_0 r \int_{t_1}^{t_2} \int_\Omega |u - v|^r \leq 0.
\]

(4.53)
Notice that by the previous estimate it follows that
\[ \| (u - v)(t) \|_{L^r(\Omega)} \leq \| (u - v)(t_0) \|_{L^r(\Omega)} \quad \text{for every} \quad t_0 \leq t \leq T_0. \]

Now, applying Theorem 3.6 in the set \( \Omega \times (t_0, T_0) \) we deduce the following estimate
\[ \| u(t) - v(t) \|_{L^r(\Omega)} \leq \frac{\| u(t_0) - v(t_0) \|_{L^r(\Omega)}}{e^{a_0(t-t_0)}} \quad \text{for every} \quad t_0 < t < T_0. \]

Thanks to the arbitrariness of \( T_0 \), we can conclude that the previous estimate holds true for every \( t > t_0 \) and hence letting \( r \to +\infty \) we obtain estimate (2.31), i.e.,
\[ \| u(t) - v(t) \|_{L^\infty(\Omega)} \leq \frac{\| u(t_0) - v(t_0) \|_{L^\infty(\Omega)}}{e^{a_0(t-t_0)}} \quad \text{for every} \quad t > t_0. \]

Now letting \( t \to +\infty \), we conclude that also (2.30) holds true. \( \square \)

**Remark 4.3.** Notice that the previous proofs work replacing the lower-order term \( a_0 u \) with a more general Caratheodory function \( a_0(x, t, u, \nabla u) \) satisfying
\[ [a_0(x, t, s, \xi) - a_0(x, t, s_0, \eta)] \text{sign}(s - s_0) \geq a_0|s - s_0| \quad \text{for every} \quad s, s_0 \in \mathbb{R}, \]
and assuming that \( a_0(x, t, u, \nabla u) \) and \( a_0(x, t, v, \nabla v) \) suitable regular \( L^1_{loc}(0, T; L^1(\Omega)) \).

**Proof of Corollary 2.2.** The assertions follow applying Theorem 2.7 once noticed that the solution \( w \) of the stationary problem (2.33) belonging to \( W^{1,p}_0(\Omega) \cap L^\infty(\Omega) \) is also a global solution (in \( L^p(0, +\infty); W^{1,p}_0(\Omega) \cap L^\infty(0, +\infty); L^\infty(\Omega) \)) of the following evolution problem
\[
\begin{cases}
  v_t - \text{div}(a(x, \nabla v)) + a_0 v = f(x) & \text{in} \quad \Omega, \\
  v = 0 & \text{on} \quad \partial \Omega \times (0, +\infty), \\
  v(x, 0) = w(x) & \text{on} \quad \Omega.
\end{cases}
\]
\( \square \)

**Proof of Theorem 2.8.** The existence of a solution constructed by approximation can be find in many papers (depending on the structure assumptions); see for example [6–9,44,52].

We complete the proof by showing the properties of these solutions enunciated in the statement of the theorem.

To this aim, we notice that every approximating sequence \( u_n \) is a Cauchy sequences in \( C([0, T]; L^1(\Omega)) \) (see [52] Claim 2 in section 2) and hence every solution \( u \) of (1.1) constructed by approximation (and consequently every solution \( v \) of (2.40) constructed by approximation) belongs to \( C([0, T]; L^1(\Omega)) \).

Hence, to conclude the proof it is sufficient to show that estimate (2.39) holds true since it implies the uniqueness of the solutions constructed by approximation.
By assumption, $u$ and $v$ are solutions constructed by approximation. Hence, $u$ is the a.e. limit in $\Omega_T$ of the regular approximating solutions $u_n \in L^\infty(\Omega_T) \cap C([0, T]; L^2(\Omega)) \cap L^p(0, T; W_0^{1,p}(\Omega))$ of (2.35) and $v$ is the a.e. limit in $\Omega_T$ of the regular approximating solutions $v_n \in L^\infty(\Omega_T) \cap C([0, T]; L^2(\Omega)) \cap L^p(0, T; W_0^{1,p}(\Omega))$ of

$$\begin{cases} (v_n)_t - \text{div}(a(x, t, \nabla v_n)) + \alpha_0 v_n = g_n(x, t) & \text{in } \Omega_T, \\ v_n = 0 & \text{on } \Gamma, \\ v_n(x, 0) = v_{0,n} & \text{on } \Omega, \end{cases} \tag{4.55}$$

where $g_n$ and $v_{0,n}$ satisfy

$$g_n \in L^\infty(\Omega_T), \quad g_n \to g \text{ in } L^1(\Omega_T), \tag{4.56}$$

$$v_{0,n} \in L^\infty(\Omega), \quad v_{0,n} \to v_0 \text{ in } L^1(\Omega). \tag{4.57}$$

Let us choose $\varphi = \left\{1 - \frac{1}{1 + |u_n - v_n|^\delta}\right\} \text{sign}(u_n - v_n)$ as test function in (2.35) and in (4.55), where $\delta > 1$ is arbitrarily fixed. Subtracting the equations obtained in this way, we deduce for every $t \in (0, T)$

$$\begin{aligned}
\int_\Omega |u_n(t) - v_n(t)| &+ \frac{1}{1 - \delta} \int_\Omega \left\{1 - \frac{1}{[1 + |u_n(t) - v_n(t)|]^\delta} \right\} \\
+ \delta \int_0^t \int_\Omega [a(x, t, \nabla u_n) - a(x, t, \nabla v_n)] \nabla (u_n - v_n) - \\
+ \alpha_0 \int_0^t \int_\Omega |u_n - v_n| \left\{1 - \frac{1}{[1 + |u_n(t) - v_n(t)|]^\delta} \right\} &\leq \int_\Omega |u_{0,n} - v_{0,n}| \\
+ \frac{1}{1 - \delta} \int_\Omega \left\{1 - \frac{1}{[1 + |u_{0,n} - v_{0,n}|]^\delta - 1} \right\} &+ \int_0^t \int_\Omega |f_n - g_n|. \tag{4.58}
\end{aligned}$$

By (4.58) and assumption (1.5), we deduce

$$\begin{aligned}
\int_{\Omega} |u_n(t) - v_n(t)| &+ \alpha_0 \int_0^t \int_\Omega |u_n - v_n| \left\{1 - \frac{1}{[1 + |u_n(t) - v_n(t)|]^\delta} \right\} \\
\leq \frac{|\Omega|}{\delta - 1} &+ \int_\Omega |u_{0,n} - v_{0,n}| + \int_0^t \int_\Omega |f_n - g_n|,
\end{aligned}$$

which implies (letting $\delta \to +\infty$)

$$\begin{aligned}
\int_{\Omega} |u_n(t) - v_n(t)| &+ \alpha_0 \int_0^t \int_\Omega |u_n - v_n| \\
\leq \int_\Omega |u_{0,n} - v_{0,n}| &+ \int_0^t \int_\Omega |f_n - g_n|. \tag{4.59}
\end{aligned}$$

As recalled above, the sequences $u_n$ and $v_n$ are Cauchy sequences in $C([0, T]; L^1(\Omega))$ and hence by (4.59) it follows that

$$\int_{\Omega} |u(t) - v(t)| \leq \int_{\Omega} |u_0 - v_0| + \int_0^t \int_{\Omega} |f - g|.$$
Proof of Theorem 2.9. The proof is an immediate consequence of Theorem 2.8 once recalled that the solution $u$ considered in Theorem 2.1, if $\alpha_0 > 0$, and in Theorem 2.2, if $\alpha_0 = 0$, is a solution obtained by approximation.

Proof of Theorem 2.10. As a first goal, we prove the existence of a global solution obtained by approximation. In detail, we construct our global solution $u$ in the following way: for every $T > 0$ arbitrarily fixed define $u(x, t)$ in $\Omega_T$ equal to the unique solution of (1.1) constructed by approximation. We recall that by Theorem 2.8 such a solution exists, is unique and belongs to $C([0, T]; L^1(\Omega))$. Notice that, again by Theorem 2.8, $u$ is well defined because if $v$ is the solution obtained by approximation of our problem solved in $\Omega \times (0, T^*)$ with $T^*$ arbitrarily chosen, then it results $u = v$ in $\Omega \times (0, \min\{T, T^*\})$. By construction, $u$ is defined in $\Omega_\infty$, is a solution obtained by approximation of (1.1) for every arbitrarily fixed $T > 0$ and belongs to $C_{loc}([0, \infty); L^1(\Omega))$. Hence, $u$ is a global solution of (1.1) obtained by approximation. Since, as recalled above, for every arbitrarily fixed $T > 0$, is unique the solution of (1.1) obtained by approximation, it is also unique the global solution $u$ of (1.1) obtained by approximation. Notice that estimate (2.39) follows by construction thanks again to Theorem 2.8.

Hence, to conclude the proof it remains to show that if $\alpha_0 > 0$ then estimate (2.41) holds true.

To this aim, let $v \in C_{loc}([0, +\infty); L^1(\Omega))$ be the global solution obtained by approximation of (2.27) and $0 < t < T$ arbitrarily fixed. Thanks to the uniqueness proved above of the global solutions obtained by approximation, we can choose the same approximation $f_n$ of the datum $f$ in (2.35) and in the approximating solutions $v_n$ of $v$, i.e., we can consider $v_n \in L^\infty(\Omega_T) \cap C([0, T]; L^2(\Omega)) \cap L^p(0, T; W_0^{1, P}(\Omega))$ solutions of

$$
\begin{cases}
(v_n)_t - \nabla(a(x, t, \nabla v_n)) + \alpha_0 v_n = f_n(x, t) & \text{in } \Omega_T, \\
v_n = 0 & \text{on } \Gamma, \\
v_n(x, 0) = v_{0,n} & \text{on } \Omega.
\end{cases}
$$

(4.60)

If $r_0 > 1$ let us consider $1 < r \leq r_0$ arbitrarily fixed and choose $\varphi = \{|\varepsilon + |u_n - v_n|^{r-1} - \varepsilon^{r-1}\} \text{sign}(u_n - v_n)$ as test function in (2.35) and in (4.60) where $\varepsilon > 0$ is arbitrarily fixed. Subtracting the results obtained in this way and thanks to assumptions (1.5) and (2.29), we deduce (letting $\varepsilon \to 0$) for every $0 \leq t_1 < t_2 \leq T$

$$
\frac{1}{r} \int_{\Omega} |u_n - v_n|^r(t_2) - \frac{1}{r} \int_{\Omega} |u_n - v_n|^r(t_1) + \alpha_0 \int_{t_1}^{t_2} \int_{\Omega} |u_n - v_n|^r \leq 0. \quad (4.61)
$$

Notice that by the previous inequality it follows that

$$
\|u_n(t) - v_n(t)\|_{L^0(\Omega)} \leq \|u_{0,n} - v_{0,n}\|_{L^0(\Omega)} \quad \text{for every } t \in (0, T).
$$

Hence, we can apply Theorem 3.6 and conclude that

$$
\|u_n(t) - v_n(t)\|_{L^r(\Omega)} \leq c_4 \frac{\|u_{0,n} - v_{0,n}\|_{L^0(\Omega)}}{\varepsilon^{\alpha_0 t}} \quad \text{for every } t \in (0, T), \quad (4.62)
$$
where $c_4$ is as in (3.23), that is $c_4 = |\Omega|^{\frac{1}{r} - \frac{1}{q_0}}$. Now the assertion follows for every $1 < r \leq r_0$ letting $n \to +\infty$. Noticing that we are assuming that $\Omega$ has finite measure, we deduce that the assertion follows also in the particular case $r = 1 < r_0$.

If otherwise $r_0 = 1$, we change the test function in $\varphi = \left\{ 1 - \frac{1}{[1 + |u_n - v_n|]^p} \right\} \text{sign}(u_n - v_n)$ where $\delta > 1$ is arbitrarily fixed. Proceeding as in the proof of estimate (4.59) above, we deduce (being now $g_n = f_n$)

$$
\int_\Omega |u_n(t_2) - v_n(t_2)| + a_0 \int_{t_1}^{t_2} \int_\Omega |u_n - v_n| \\
\leq \int_\Omega |u_n(t_1) - v_n(t_1)| \quad \text{for every} \quad 0 \leq t_1 < t_2 < T,
$$

(4.63)

from which it follows also that

$$
\|u_n(t) - v_n(t)\|_{L^1(\Omega)} \leq \|u_{0,n} - v_{0,n}\|_{L^1(\Omega)} \quad \text{for every} \quad t \in (0, T).
$$

Applying again Theorem 3.6 (with now $r = r_0 = 1$), we obtain

$$
\|u_n(t) - v_n(t)\|_{L^1(\Omega)} \leq \frac{\|u_{0,n} - v_{0,n}\|_{L^1(\Omega)}}{e^{a_0 t}} \quad \text{for every} \quad t \in (0, T),
$$

(4.64)

which implies estimate (2.41) letting $n \to +\infty$.

**Proof of Theorem 2.11.** The result is an immediate consequence of Theorems 2.4 and 2.10 being the solution constructed in Theorem 2.4 a global solution of (2.26) obtained by approximation.

**Proof of Theorem 2.12.** We start noticing that by the structure bound (1.3) together with the assumption that $v$ is in $L^p_{loc}([0, +\infty); W_0^{1,p}(\Omega))$ it follows that $v$ belongs also to $C_{loc}([0, +\infty); L^1(\Omega))$. Now let $T > 0$ arbitrarily fixed. Since $u$ is a global solution obtained by approximation it is the a.e. limit in $\Omega_T$ of the solutions $u_n \in L^\infty(\Omega_T) \cap C([0, T]; L^2(\Omega)) \cap L^p(0, T; W_0^{1,p}(\Omega))$ of (2.35). Let us choose $\varphi = \left\{ 1 - \frac{1}{[1 + |u_n - v|]^p} \right\} \text{sign}(u_n - v)$ where $\delta > 1$ is arbitrarily fixed as a test function in (2.35) and in (2.27). Subtracting the results obtained in this way and thanks to assumptions (1.5) and (2.29), we deduce for every $0 \leq t_1 < t_2 < T$ (letting $\delta \to +\infty$)

$$
\int_\Omega |u_n(t_2) - v(t_2)| - \int_\Omega |u_n(t_1) - v(t_1)| + a_0 \int_{t_1}^{t_2} \int_\Omega |u_n - v| \\
\leq \int_{t_1}^{t_2} g(t)dt \quad \text{where} \quad g(t) \equiv \int_\Omega |f_n(t) - f(t)|.
$$

Applying Theorem 3.7, we deduce that for every $t \in (0, T]

$$
\int_\Omega |u_n(t) - v(t)| \leq \|u_{0,n} - v_0\|_{L^1(\Omega)} e^{-a_0 t} + \int_0^t \int_\Omega |f_n - f|,
$$

from which, recalling that (2.36) holds true, the assertion follows letting $n \to +\infty$ being $T > 0$ arbitrarily fixed.
Proof of Theorem 2.13. We observe that it is sufficient to prove the uniqueness of the solutions of (1.1) belonging $L^p_{loc}((0, T]; W_0^{1, p}(\Omega)) \cap C([0, T]; L^1(\Omega))$. Now, the proof proceeds by contradiction. Hence, let $u$ and $v$ solutions of (1.1) belonging $L^p_{loc}((0, T]; W_0^{1, p}(\Omega)) \cap C([0, T]; L^1(\Omega))$. Let $\delta > 1$ be arbitrarily fixed and choose $\varphi = \left\{ 1 - \frac{1}{1 + |u - v|} \right\}$ sign$(u - v)$ as a test function in the equations satisfied by $u$ and $v$. Subtracting the results obtained in this way and thanks to the assumption (2.29), we deduce for every $0 < t_0 < t \leq T$

$$\int_{\Omega} |u(t) - v(t)| + \frac{1}{1 - \delta} \int_{\Omega} \left\{ 1 - \frac{1}{1 + |u(t) - v(t)|^{\delta-1}} \right\} \nabla(u - v) + \frac{1}{1 - \delta} \int_{\Omega} \left\{ 1 - \frac{1}{1 + |u(t) - v(t)|^{\delta-1}} \right\} \leq \int_{\Omega} |u(t_0) - v(t_0)|.$$ (4.65)

Thanks to the assumption (1.5), by the previous inequality (dropping the nonnegative terms) we deduce

$$\int_{\Omega} |u(t) - v(t)| \leq \frac{\|\Omega\|}{\delta - 1} + \int_{\Omega} |u(t_0) - v(t_0)|,$$

and thus, letting $\delta \to +\infty$ we conclude that for every $0 < t_0 < t \leq T$

$$\int_{\Omega} |u(t) - v(t)| \leq \int_{\Omega} |u(t_0) - v(t_0)|.$$ Now, recalling the regularity $C([0, T]; L^1(\Omega))$ of $u$ and $v$, the assert follows letting $t_0 \to 0^+$. \qed

Acknowledgements

I would like to thank the anonymous referee for suggesting me to study the case with the reaction term $-\alpha_0 u$ (see Theorem 2.3), for recommending many references and for all the remarks that have improved the readability and clarity of this paper.
