ALGEBRAS GENERATED BY ELEMENTS WITH GIVEN SPECTRUM AND SCALAR SUM AND KLEINIAN SINGULARITIES

ANTON MELLIT

Abstract. We consider algebras $e_i \Pi^\lambda(Q)e_i$ where $\Pi^\lambda(Q)$ is the deformed preprojective algebra of weight $\lambda$ and $i$ is some vertex of $Q$ in the case when $Q$ is an extended Dynkin diagram and $\lambda$ lies on the hyperplane orthogonal to the minimal positive imaginary root $\delta$. We prove that the center of $e_i \Pi^\lambda(Q)e_i$ is isomorphic to $O^\lambda(Q)$ which is a deformation of coordinate ring of Kleinian singularity which corresponds to $Q$. Also we find the minimal $k$ for which the standard identity of degree $k$ holds in $e_i \Pi^\lambda(Q)e_i$. We prove that algebras $A_{P_1, \ldots, P_n; \mu} = \mathbb{C}\langle x_1, \ldots, x_n | P_i(x_i) = 0, \sum_{i=1}^n x_i = \mu e \rangle$ are the special case of algebras $e_i \Pi^\lambda(Q)e_i$ for star-like quivers $Q$ with origin $c$.

INTRODUCTION

Consider the problem of description of $n$-tuples of hermitian operators $\{A_i\}$ in a Hilbert space satisfying given restrictions on spectra $\sigma(A_i) \subset M_i$ with $M_i \subset \mathbb{R}$ finite and relation $\sum_{i=1}^n A_i = \mu I$, with $I$ - the identity and $\mu \in \mathbb{R}$. Study of such $n$-tuples is equivalent to study of *-representations of certain *-algebra. Forgetting the *-structure we arrive to the following class of algebras.

Definition 1. Let $P_1, \ldots, P_n$ be complex polynomials in one variable and $\mu \in \mathbb{C}$. We put inessential restriction $P_i(0) = 0$. Define algebra

$$A_{P_1, \ldots, P_n; \mu} = \mathbb{C}\langle x_1, \ldots, x_n | P_i(x_i) = 0 (i = 1, \ldots, n), \sum_{i=1}^n x_i = \mu e \rangle.$$ 

In joint work of the author with Yu. Samoilenko and M. Vlasenko (see [1]) we studied some properties of such algebras: we computed growth of these algebras and proved existence of polynomial identities in certain cases (in fact, finiteness over center was proved).

These algebras are closely related to deformed preprojective algebras of W. Crawley-Boevey and M.P. Holland ([2]). We briefly recall their definition. Let $Q$ be a quiver with vertex set $I$. Write $\bar{Q}$ for the double quiver of $Q$, i.e. quiver obtained by adding a reverse arrow $a^* : j \to i$ for every arrow $a : i \to j$, and write $\mathbb{C}Q$ for its path algebra, which has basis the paths in $\bar{Q}$, including a trivial path $e_i$ for each vertex $i$. 

\[ \text{2000 Mathematics Subject Classification. Primary: 16S99; Secondary: 14B07.} \]
If \( \lambda = (\lambda_i) \in \mathbb{C}^I \), then the deformed preprojective algebra of weight \( \lambda \) is

\[
\Pi^\lambda(Q) = \mathbb{C}\bar{Q}/\left( \sum_{a \in \text{Arrows}(Q)} [a, a^*] - \lambda \right),
\]

where \( \text{Arrows}(Q) \) denotes the set of arrows of \( Q \), and \( \lambda \) is identified with the element \( \sum_{i \in I} \lambda_i e_i \).

Let \( A = A_{P_1, \ldots, P_n; \mu} \). Consider quiver \( Q(A) \) with vertices

\[
I = \{(i, j) | i = 1, \ldots, n, j = 1, \ldots, \deg P_i - 1 \} \cup \{c\}
\]

and arrows

\[
\{a_{ij} : (i, j) \rightarrow (i, j - 1) | i = 1, \ldots, n, j = 1, \ldots, \deg P_i - 1 \},
\]

where \((i, 0)\) is identified with \( c \) for \( i = 1, \ldots, n \).

Note that the graph \( Q \) coincides with the graph of algebra \( A \), considered in [1]. Here is an example of quiver \( Q \) for the case \( n = 3, \deg P_1 = 2, \deg P_2 = 3, \deg P_3 = 2 \):

\[
\begin{array}{cccccc}
(1, 1) & \overrightarrow{a_{12}} & (1, 2) & \cdots & \overrightarrow{a_{1 \deg P_1 - 1}} & (1, \deg P_1 - 1) \\
\overleftarrow{a_{11}} & (2, 1) & \overrightarrow{a_{22}} & (2, 2) & \cdots & \overrightarrow{a_{2 \deg P_2 - 1}} & (2, \deg P_2 - 1) \\
\overleftarrow{a_{n1}} & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
(1, 1) & \overrightarrow{a_{12}} & (1, 2) & \cdots & \overrightarrow{a_{1 \deg P_1 - 1}} & (1, \deg P_1 - 1) \\
\end{array}
\]

The first result establishes connection between algebras \( A_{P_1, \ldots, P_n; \mu} \) and deformed preprojective algebras.

**Theorem 1.** Algebra \( A = A_{P_1, \ldots, P_n; \mu} \) is isomorphic to \( e_c \Pi^\lambda(Q)e_c \) under the isomorphism sending \( x_i \) to \( a_{i1}a_{i1}^* \) for \( Q = Q(A) \) and

\[
\lambda = \sum_{i=1}^n \sum_{j=1}^{\deg P_i - 1} (\alpha_{ij-1} - \alpha_{ij})e_{ij} + \mu e_c,
\]

where \( \alpha_{i0}, \alpha_{i1}, \ldots, \alpha_{i \deg P_i - 1} \) are all roots of the polynomial \( P_i \) taken with multiplicities in any order with \( \alpha_{i0} = 0 \).

Consider the case when graph \( Q \) is an extended Dynkin diagram of type \( \tilde{A}_n, \tilde{D}_n \) or \( \tilde{E}_n \). The following picture shows all such graphs along with coordinates of the so-called minimal imaginary root \( \delta \in \mathbb{C}^I \). Boxed vertex is the extending vertex.
In [2] they proved that $\Pi^\lambda(Q)$ is a PI-algebra (on PI algebras see [3]) if and only if $\delta \cdot \lambda = 0$. Also they studied algebra $O^\lambda(Q)$ which is $e_0\Pi^\lambda(Q)e_0$ where 0-th vertex is the extending vertex of $Q$, and proved that this algebra is commutative if and only if $\delta \cdot \lambda = 0$. For $\lambda = 0$ the algebra $O^0(Q)$ coincides with the coordinate ring of the corresponding Kleinian singularity.

In this paper we consider algebras $e_i\Pi^\lambda e_i$ for arbitrary $i \in I$. For the case $\delta \cdot \lambda = 0$ we study center of such algebra and find minimal number $k$ for which it possesses standard identity of degree $k$, i.e.

$$\sum_{\pi \in S_k} \text{sign}(\pi) \prod_{i=1}^{k} x_{\pi(i)} = 0.$$  

We denote by $S_k$ the group of permutations of $k$ elements.

We obtain the following theorems:

**Theorem 2.** If $Q$ is an extended Dynkin diagram $\widetilde{A}_n$, $\widetilde{D}_n$ or $\widetilde{E}_n$, $\delta \cdot \lambda = 0$ and $i \in I$ is some vertex of $Q$ then center of $e_i\Pi^\lambda(Q)e_i$ is isomorphic to $O^\lambda(Q) = e_0\Pi^\lambda(Q)e_0$ where 0-th vertex is the extending vertex of $Q$.

Theorem 3. If $Q$ is an extended Dynkin diagram $\tilde{A}_n$, $\tilde{D}_n$ or $\tilde{E}_n$, $\delta \cdot \lambda = 0$ and $i \in I$ is some vertex of $Q$ then $e_i \Pi^\lambda e_i$ possesses standard identity of degree $2\delta_i$ and it is the minimal number with such property.

1. Representations of groups

Suppose $V$ is a two dimensional complex vector space with simplectic form $\omega$. Let $G$ be a finite subgroup of $SL(V)$. Suppose irreducible representations of $G$ are precisely $\{V_i\}_{i \in I}$ where $I = \{0, 1, 2, \ldots, n\}$ with $V_0$ — the trivial one. Suppose $V \otimes V_i = \bigoplus_{j=1}^n m_{ij} V_j$.

Then the McKay graph of $G$ is defined to be a graph with vertex set $I$ and number of edges between $i$ and $j$ is $m_{ij}$ (we will always have $m_{ij} = m_{ji}$). According to J. McKay ([4]) McKay graphs of finite subgroups of $SL(V)$ are extended Dynkin diagrams: $\tilde{A}_n$ for cyclic groups, $\tilde{D}_n$ for dihedral groups and $\tilde{E}_6$, $\tilde{E}_7$, $\tilde{E}_8$ for binary tetrahedral, octahedral and icosahedral groups. Dimensions of irreducible representations are $\dim V_i = \delta_i$. Let us fix some orientation of McKay graph of $G$ thus obtaining a quiver $Q$.

Let $M$ be some $CG$-module. Consider vector space $F_0(M) = T(V^*) \otimes M$ where

$$T(V^*) = \bigoplus_{i=0}^\infty V^* \otimes^i V^*$$

is the tensor algebra of $V^*$. Equip $F_0(M)$ with the componentwise action of $G$. Then we can consider $F(M) = F_0(M)^G$ — the subspace of $G$-invariant vectors. Note that if $M$ is algebra and multiplication respects action of $G$ then both $F_0(M)$ and $F(M)$ become graded algebras with grading $F_0(M)_i = V^* \otimes^i M$ and $F(M)_i = (F_0(M)_i)^G$. Consider algebra $F(End_C(V_\Sigma))$, where $V_\Sigma$ is the direct sum of all irreducible $CG$-modules and $G$ acts on $End_C(V_\Sigma)$ by conjugation. Clearly $F(End_C(V_\Sigma))_0$ is the same as $(End_C(V_\Sigma))^G$, which in its turn can be identified with $C^I$. Our aim is to build a graded algebra isomorphism $\varphi$ from $\mathbb{C}Q$ to $F(End_C(V_\Sigma))$ such that

$$\varphi \text{ is identity on } C^I$$

$$\varphi(\sum_{a \in Arrows(Q)} [a, a^*]) = \delta \omega.$$  

We accomplish this in two steps:

Lemma 1.1. Natural homomorphism

$$F(End_C(V_\Sigma))_i \otimes_{F(End_C(V_\Sigma))_0} F(End_C(V_\Sigma))_j \rightarrow F(End_C(V_\Sigma))_{i+j}$$

is an isomorphism.
Proof. We make some identifications
\[ F(\text{End}_C(V_\Sigma))_i = (V^{* \otimes i} \otimes \text{End}_C(V_\Sigma))^G \cong \text{Hom}_G(V_\Sigma, V^{* \otimes i} \otimes V_\Sigma) \]
\[ \cong \bigoplus_{i \in I} \text{Hom}_C(C, C^a_i), \]
where
\[ V^{* \otimes i} \otimes V_\Sigma \cong \bigoplus_{i \in I} V^{a_i}. \]
\[ F(\text{End}_C(V_\Sigma))_j = (V^{* \otimes j} \otimes \text{End}_C(V_\Sigma))^G \cong \text{Hom}_G(V^{* \otimes i} \otimes V_\Sigma, V_\Sigma) \]
\[ \cong \bigoplus_{i \in I} \text{Hom}_C(C^b_i, C), \]
where
\[ V^{* \otimes j} \otimes V_\Sigma \cong \bigoplus_{i \in I} V^{a_i}. \]
\[ F(\text{End}_C(V_\Sigma))_{i+j} = (V^{* \otimes (i+j)} \otimes \text{End}_C(V_\Sigma))^G \]
\[ \cong \text{Hom}_G(V^{* \otimes i} \otimes V_\Sigma, V^{* \otimes j} \otimes V_\Sigma) \cong \bigoplus_{i \in I} \text{Hom}_C(C^b_i, C^a_i). \]
Recall that
\[ F(\text{End}_C(V_\Sigma))_0 \cong \bigoplus_{i \in I} C. \]
Now the statement is clear. \qed

This lemma implies that the natural homomorphism from tensor algebra of \( F(\text{End}_C(V_\Sigma))_1 \) over \( F(\text{End}_C(V_\Sigma))_0 \) to \( F(\text{End}_C(V_\Sigma)) \) is an isomorphism. Graded algebra \( CQ \) possesses the same property, so it is clear that for establishing isomorphism of graded algebras which is identity on \( C' \) it is necessary and sufficient to establish isomorphism of subbimodules in degree 1. Decompose \( F(\text{End}_C(V_\Sigma)) \) by primitive idempotents of \( C' \):
\[ F(\text{End}_C(V_\Sigma))_1 = (V^* \otimes \text{End}_C(V_\Sigma))^G \cong \bigoplus_{i,j \in I} \text{Hom}_G(V \otimes V_i, V_j). \]
Clearly \( \text{Hom}_G(V \otimes V_i, V_j) \) vanish if there are no arrows from \( i \) to \( j \) in \( Q \) and is one dimensional if there is arrow from \( i \) to \( j \) in \( Q \). Subbimodule of \( C' \) in degree 1 has similar decomposition. So any assignment \( a \rightarrow \varphi(a) \in \text{Hom}_G(V \otimes V_i, V_j), \varphi(a) \neq 0 \) for \( a \in \text{Arrows}(Q) \) induces some isomorphism of graded algebras \( \varphi : CQ \rightarrow F(\text{End}_C(V_\Sigma)) \).

**Proposition 1.1.** For every arrow \( a : i \rightarrow j \) of \( Q \) choose any nonzero representative \( \varphi(a) \in \text{Hom}_G(V \otimes V_i, V_j) \). It is possible to choose \( \varphi(a^*) \in \text{Hom}_G(V_j, V^* \otimes V_i) \) such that
\[ \text{tr}(\iota \otimes \text{Id}_{V_i})\varphi(a^*)\varphi(a) = \dim V_i \dim V_j, \]
where \( \iota : V^* \rightarrow V \) is such that
\[ f(x) = \omega(\iota(f), x) \text{ for } f \in V^* \text{ and } x \in V. \]
This induces isomorphism of algebras which satisfies property (*)).

Proof. As for the possibility of choosing such a $\varphi(a^*)$, in decomposition of $V \otimes V_i$ into direct sum of indecomposable CG-modules $V_j$ occurs exactly once, so if we choose any nonzero $\varphi(a^*) \in \text{Hom}_G(V \otimes V_i, V_j)$, we obtain that

$$(\iota \otimes \text{Id}_{V_i}) \varphi(a^*) \varphi(a)$$

is a projection on $V_j$ in $V \otimes V_i$ multiplied by some complex constant, so its trace is nonzero and by multiplication by some factor it is possible to make the trace accepting any complex value. It is only needed check that

$$\sum_{a \in \text{Arrows}(Q)} [\varphi(a), \varphi(a^*)] = \delta \omega.$$  

Choose some vertex $i$ and multiply both sides by $e_i$:  

$$(1.1) \quad \sum_{j \in I, a: j \rightarrow i, a \in \text{Arrows}(Q)} \varphi(a) \varphi(a^*) - \sum_{j \in I, a: i \rightarrow j, a \in \text{Arrows}(Q)} \varphi(a^*) \varphi(a) = \delta_i \omega e_i.$$  

Both sides belong to $\text{Hom}_G(V \otimes V \otimes V_i, V_i)$, which can be identified with $\text{Hom}_G(V \otimes V_i, V_i^* \otimes V_i)$ by 'lifting' first element of tensor product. Apply $\iota \otimes \text{Id}_{V_i}$ to both sides. Since $(\omega(x))(y) = \omega(x, y)$ and $(\omega(x))(y) = \omega(\iota(\omega(x)), y)$ we have $\iota(\omega(x)) = -x$ and

$$(\iota \otimes \text{Id}_{V_i}) \delta_i \omega e_i = -\delta_i \text{Id}_{V \otimes V_i}.$$  

Recall that each $(\iota \otimes \text{Id}_{V_i}) \varphi(a) \varphi(a^*)$ and $(\iota \otimes \text{Id}_{V_i}) \varphi(a^*) \varphi(a)$ which occurs in (1.1) is a projection on a summand $V_j$ multiplied by some complex number where $j$ is another endpoint of $a$ different from $i$. Denote this projection by $p_j$. Then

$$\begin{align*}
(\iota \otimes \text{Id}_{V_i}) \varphi(a) \varphi(a^*) &= \frac{\text{tr}((\iota \otimes \text{Id}_{V_i}) \varphi(a) \varphi(a^*))}{\dim V_j} p_j \\
-(\iota \otimes \text{Id}_{V_i}) \varphi(a^*) \varphi(a) &= \frac{-\text{tr}((\iota \otimes \text{Id}_{V_i}) \varphi(a^*) \varphi(a))}{\dim V_j} p_j.
\end{align*}$$

By definition

$$\text{tr}((\iota \otimes \text{Id}_{V_i}) \varphi(a^*) \varphi(a)) = \dim V_i \dim V_j.$$  

There is an identity

$$\text{tr}((\iota \otimes \text{Id}_{V_i}) xy) = -\text{tr}((\iota \otimes \text{Id}_{V_i}) yx),$$

which holds for every $x \in \text{Hom}_C(V \otimes V_j, V_i)$ and $y \in \text{Hom}_C(V \otimes V_i, V_j)$. It is enough to check this identity for $x = f_1 \otimes x_0$ and $y = f_2 \otimes y_0$ where $f_1, f_2 \in V^*$, $x_0 \in \text{Hom}_C(V_j, V_i)$ and $y_0 \in \text{Hom}_C(V_i, V_j)$:

$$\begin{align*}
\text{tr}((\iota \otimes \text{Id}_{V_i}) xy) &= \text{tr}(\iota(f_1)f_2 \otimes x_0y_0) = f_2(\iota(f_1)) \text{tr}(x_0y_0) \\
&= \omega(\iota(f_2), \iota(f_1)) \text{tr}(x_0y_0) = -\omega(\iota(f_1), \iota(f_2)) \text{tr}(y_0x_0) \\
&= -f_1(\iota(f_2)) \text{tr}(y_0x_0) = -\text{tr}(\iota(f_2)f_1 \otimes y_0x_0) = -\text{tr}((\iota \otimes \text{Id}_{V_i}) yx).
\end{align*}$$
Apply this identity:

\[
\text{tr}( (\iota \otimes \text{Id}_V) \varphi(a) \varphi(a^*) ) = - \text{tr}( (\iota \otimes \text{Id}_V) \varphi(a^*) \varphi(a) ) = - \dim V_i \dim V_j.
\]

It follows that \( \iota \otimes \text{Id}_V \) applied to lefthand side of (1.1) equals to

\[
- \dim V_i \sum_{j \in I, a:i \rightarrow j, \ a \in \text{Arrows}(\overline{Q})} p_j = - \dim V_i \text{Id}_V \otimes V_i
\]

and recalling that \( \delta_i = \dim V_i \) we are done. \( \square \)

The next corollary summarizes what have been done in this section.

**Corollary 1.1.** Algebra \( \Pi^\lambda(Q) \) is isomorphic to algebra

\[
(T(V^*) \otimes \text{End}_C(V_\Sigma))^G / (\delta \omega - \lambda).
\]

Moreover, this is isomorphism of filtered algebras with filtrations induced from gradings of \( \mathbb{C}Q \) and \( T(V^*) \).

2. Case of \( \lambda = 0 \)

In this section we are going to prove theorems 2 and 3 for the case \( \lambda = 0 \). Key is the following lemma:

**Lemma 2.1.** Algebra \( \Pi^0(Q) \) is isomorphic to algebra of polynomial \( G \)-equivariant maps from \( V \) to \( \text{End}_C(V_\Sigma) \), i.e. the algebra

\[
(\text{Sym}(V^*) \otimes \text{End}_C(V_\Sigma))^G,
\]

where \( \text{Sym}(V^*) \) is the algebra of symmetric tensors of \( V^* \). Moreover, this is isomorphism of graded algebras.

**Proof.** We already know that \( \Pi^0(Q) \) is isomorphic to

\[
(T(V^*) \otimes \text{End}_C(V_\Sigma))^G / (\delta \omega) = (T(V^*) \otimes \text{End}_C(V_\Sigma))^G / \omega.
\]

Since

\[
\text{Sym}(V^*) \otimes \text{End}_C(V_\Sigma) = (T(V^*) / \omega) \otimes \text{End}_C(V_\Sigma) = (T(V^*) \otimes \text{End}_C(V_\Sigma)) / \omega,
\]

it is enough to prove that the idempotent

\[
\varepsilon = \frac{1}{|G|} \sum_{g \in G} g
\]

maps ideal generated by \( \omega \) in \( T(V^*) \otimes \text{End}_C(V_\Sigma) \) to the ideal generated by \( \omega \) in \( (T(V^*) \otimes \text{End}_C(V_\Sigma))^G \). To prove this take some \( f \in V^{* \otimes i} \otimes \text{End}_C(V_\Sigma), g \in V^{* \otimes j} \otimes \text{End}_C(V_\Sigma) \) and consider \( \varepsilon(f \omega g) \). Note that \( f \omega g \) is antisymmetric with respect to \( i + 1 \)-th and \( i + 2 \)-th argument. It follows that \( \varepsilon(f \omega g) \) is antisymmetric with respect to \( i + 1 \)-th and \( i + 2 \)-th argument as well. Since

\[
\varepsilon(f \omega g) \in (V^{* \otimes (i+j+2)} \otimes \text{End}_C(V_\Sigma))^G
\]
and we know from lemma \[1\] that

\[(V^{*} \otimes (i+j+2) \otimes \text{End}_C(V_2))^G = (V^{*} \otimes \text{End}_C(V_2))^G \otimes_{C^G} (V^{*} \otimes 2 \otimes \text{End}_C(V_2))^G \otimes_{C^G} (V^{*} \otimes j \otimes \text{End}_C(V_2))^G\]

we can decompose

\[\varepsilon(f \omega g) = \sum_{k=1}^{K} f_k \omega_k g_k\]

with \(f_k \in (V^{*} \otimes \text{End}_C(V_2))^G\), \(g_k \in (V^{*} \otimes j \otimes \text{End}_C(V_2))^G\) and \(\omega_k \in (V^{*} \otimes 2 \otimes \text{End}_C(V_2))^G\). Denote by \(\tau\) operator acting on elements of \((V^{*} \otimes (i+j+2) \otimes \text{End}_C(V_2))^G\) by interchanging \(i + 1\)-th and \(i + 2\)-th arguments. Then

\[\tau \varepsilon(f \omega g) = \sum_{k=1}^{K} f_k \omega'_k g_k\]

with \(\omega'_k\) is obtained from \(\omega_k\) by interchanging first two arguments. Hence

\[\varepsilon(f \omega g) = \frac{1}{2}(\varepsilon(f \omega g) - \tau \varepsilon(f \omega g)) = \frac{1}{2} \sum_{k=1}^{K} f_k (\omega_k - \omega'_k) g_k.\]

Since \(\omega_k - \omega'_k \in \text{Hom}_G(V \otimes V, \text{End}_C(V_2))\) is antisymmetric and \(V\) is two dimensional, it can be represented as \(\omega x_k\) with \(x_k \in \text{End}_C(V_2)^G\). Thus

\[\varepsilon(f \omega g) = \frac{1}{2} \sum_{k=1}^{K} f_k \omega x_k g_k\]

with \(f_k\), \(x_k\) and \(g_k\) from \((T(V^{*}) \otimes \text{End}_C(V_2))^G\). This completes the proof. \(\square\)

The next propositions follow immediately.

**Proposition 2.1.** Algebra \(e_i \Pi^0(Q)e_i\) is isomorphic to the algebra of polynomial \(G\)-equivariant maps from \(V\) to \(\text{End}_C(V_i)\) for any \(i \in I\). In particular, \(\mathcal{O}^0(Q) = e_0 \Pi^0(Q)e_0\) is isomorphic to the algebra of invariants of \(G\) on \(V\).

**Proposition 2.2.** Algebra \(e_i \Pi^0(Q)e_i\) possesses standard identity of degree \(2\delta_i\) for any \(i \in I\).

**Proposition 2.3.** There is a graded inclusion from \(e_0 \Pi^0(Q)e_0\) to the center of \(\Pi^0(Q)\) and graded inclusions from \(e_0 \Pi^0(Q)e_0\) to center of \(e_i \Pi^0(Q)e_i\) for \(i \in I\) induced by inclusions \(C \subset \text{End}_C(V_2)\) and \(C \subset \text{End}_C(V_i)\) correspondingly.

For any \(i \in I\) and \(x \in V\) denote by \(\mu_i(x)\) the subset of \(\text{End}_C(V_i)\) defined by

\[\mu_i(x) = \{f(x) | f\text{ is a polynomial }G\text{-equivariant map from }V\text{ to }\text{End}_C(V_i)\}\]

For the rest we need the following statement:
Lemma 2.2. The set of $x \in V$ for which $\mu_i(x) = \text{End}_C(V_i)$ is algebraically dense for any $i \in I$.

Proof. Suppose $f : V \longrightarrow \mathbb{C}$ is a non-constant $G$-invariant polynomial function. Then its differential $df$ is a polynomial $G$-equivariant map from $V$ to $V^*$. Denote by $U$ the set of $x \in V$ for which $(df(x))(x) \neq 0$. Clearly $U$ is open and $U$ is not empty since $(df(x))(x) = 0$ implies $f$ is a constant. Denote by $U'$ the subset of $U$ of all $x$ such that $f(x) \neq 0$. Since $U'$ is open and not empty it is dense. We will prove that every $x$ from $U'$ satisfies the required condition. So let $f(x) \neq 0$ and let $(df(x))(x) \neq 0$. Then $udf(x) \in V$ ($u : V^* \longrightarrow V$ is such that $\omega(u(y_1), y_2) = y_1(y_2)$ for every $y_1 \in V^*$ and $y_2 \in V$) is not a multiple of $x$ because if $udf(x) = Cx$, $C \in \mathbb{C}$ then

$$(df(x))(x) = \omega(udf(x), x) = \omega(Cx, x) = 0.$$  

It follows that $f(x)x$ and $udf(x)$ span $V$. Since $g_1 : V \longrightarrow V$ defined by $g_1(y) = f(y)y$ and $g_2 : V \longrightarrow V$ defined by $g_2(y) = df(y)$ are polynomial and $G$-equivariant we have that every element of $V$ is value in $x$ of some polynomial $G$-equivariant map from $V$ to $V$. It follows that for every $k$ every element of $V^{\otimes k}$ is value in $x$ of some polynomial $G$-equivariant map from $V$ to $V^{\otimes k}$. Since every finite dimensional $\mathbb{C}G$-module is submodule of $V^{\otimes k}$ for some $k$, the statement holds for every finite dimensional $\mathbb{C}G$-module, in particular for $\text{End}_C(V_i)$. 

This lemma implies that there is no $k < 2\delta$ such that $e_i\Pi^0(Q)e_i$ has standard identity of degree $k$ (since some factor of $e_i\Pi^0(Q)e_i$ is algebra of matrices $\delta_i \times \delta_i$). Moreover it implies that every polynomial map from $V$ to $\text{End}_C(V_i)$ which commutes with all $G$-equivariant polynomial maps from $V$ to $\text{End}_C(V_i)$ accepts only scalar values thus the inclusion of proposition 2.3 is in fact an isomorphism.

Corollary 2.1. Theorems 2 and 3 are valid when $\lambda = 0$.

3. Regularity of the multiplication law

Denote by $S_n$ the $\mathbb{C}^I$-bimodule $(\text{Sym}^n(V^*) \otimes \text{End}_C(V_2))^G$, by $S$ the graded algebra $(\text{Sym}(V^*) \otimes \text{End}_C(V_2))^G$, by $T_n$ the $\mathbb{C}^I$-bimodule $(V^* \otimes \text{End}_C(V_2))^G$ and by $T$ the graded algebra $(T(V^*) \otimes \text{End}_C(V_2))^G$. In this section we will show that all algebras of the family $\Pi^k(Q)$ can be identified with an algebra which is $S$ as a vector space and the multiplication law in it polynomially depends on $\lambda$. For every $k = 0, 1, 2, \ldots$ we construct an operator

$$\pi_k^\lambda : T_k \longrightarrow \bigoplus_{i=0}^k S_i$$

such that

(1) $\pi_k^\lambda(x) = x$ for $x \in S_k$. 

Then the family of operators $\pi_k$ define an operator $\pi^\lambda$ acting from $T$ to $S$. It is clear that $\pi^\lambda$ is a projection with image $S$, the second property of $\pi_k$ guarantee that $\pi^\lambda(x)$ is equivalent to $x$ in algebra $\Pi^\lambda(Q)$, whilst the third property implies that equivalent in $\Pi^\lambda(Q)$ elements are mapped to identical elements. Combined this gives the isomorphism of $\Pi^\lambda(Q)$ and $S$ as filtered vector spaces and multiplication in $\Pi^\lambda(Q)$ transferred to $S$ can be easily written as

$$x \times y = \pi^\lambda(x \otimes y),$$

which polynomially depends on $\lambda$. It is left to show that the family of operators with properties (1)-(4) exist.

Clearly for $k = 0$ and $k = 1$ we may take an identity operators. Then we prove existence of $\pi_k^\lambda$ by induction. Fix some $\lambda \in \mathbb{C}^I$ and integer $k \geq 2$. Define operators

$$\tau_i : T_k \oplus \bigoplus_{j=0}^{k-2} S_j \rightarrow T_k \oplus \bigoplus_{j=0}^{k-2} S_j \text{ for } i = 1, \ldots, k - 1$$

as

$$\tau_i(x) = 0 \text{ for } x \in \bigoplus_{j=0}^{k-2} S_j,$$

$$\tau_i(x) = 0 \text{ for } x \in T_k \text{ such that } x \text{ is symmetric with respect to } i\text{-th and } i+1\text{-th arguments},$$

$$\tau_i(f \omega g) = f \omega g - \pi^{k-2}_\lambda (f \delta^{-1} \lambda g),$$

which defines $\tau_i$ for $x \in T_k$ such that $x$ is antisymmetric with respect to $i\text{-th and } i + 1\text{-th arguments}$. Put $\rho_i = 1 - 2 \tau_i$. We prove the following fact:

**Proposition 3.1.** The family of operators $(\rho_i)$ satisfy conditions

1. $\rho_i^2 = 1$,
2. $\rho_i \rho_j = \rho_j \rho_i$ for $|i - j| > 1$,
3. $\rho_i \rho_{i+1} \rho_i = \rho_{i+1} \rho_i \rho_{i+1},$

so $(\rho_i)$ induce a representation of the group of permutations of $k$ elements.

**Proof.** Property (1) is easy. Consider the property (2). Assume $j > i$. It is enough to check the property for argument of the form

$$x = f_1 \omega f_2 \omega f_3 \text{ for } f_1 \in T_{i-1}, \ f_2 \in T_{j-i-2}, \ f_3 \in T_{k-j-1}.$$

Then

$$\rho_i \rho_j x - \rho_j \rho_i x = \pi^{k-2}_\lambda (f_1 \omega f_2 \delta^{-1} \lambda f_3 - f_1 \omega f_2 \delta^{-1} \lambda f_3)$$

$$= \pi^{k-4}_\lambda (f_1 \delta^{-1} \lambda f_2 \delta^{-1} \lambda f_3 - \pi^{k-4}_\lambda (f_1 \delta^{-1} \lambda f_2 \delta^{-1} \lambda f_3) = 0.$$
by the induction hypothesis. Consider the property (3). Denote by 
\( \rho_i', \ i = 1, 2, \ldots, k - 1 \) the operator in \( T_k \) which acts on \( x \in T_k \) by
interchanging of \( i \)-th and \( i + 1 \)-th arguments. Then, clearly operators 
\( \rho_i' \) satisfy conditions (1)-(3). Choose some \( i \neq k - 1 \). Since there is
no element of \( T_k \) which is antisymmetric with respect to arguments \( i, i + 1, i + 2 \) the following operator vanishes on \( T_k \):
\[
1 - \rho_i - \rho_{i+1} - \rho_i'\rho_{i+1}\rho_i' + \rho_i'\rho_i + \rho_{i+1}\rho_i' = 0.
\]
If we substitute \( \rho_i' = 1 - 2\tau_i \) we obtain that
\[
\tau_i\tau_{i+1}\tau_i' = \frac{1}{4}\tau_i' \quad \text{and} \quad \tau_{i+1}\tau_i\tau_{i+1}' = \frac{1}{4}\tau_{i+1}'.
\]
If we prove that
\[
\tau_i\tau_j\tau_i = \frac{1}{4}\tau_i \quad \text{for} \ |i - j| = 1,
\]
the property (3) would follow. But if \( |i - j| = 1 \) then
\[
\tau_i\tau_j\tau_i = \tau_i\tau_j\tau_i = \tau_i\tau_j\tau_i = \frac{1}{4}\tau_i\tau_i' = \frac{1}{4}\tau_i' = \frac{1}{4}\tau_i,
\]
here we consider \( \tau_m, m = 1, 2, \ldots, k - 1 \) as an operator in \( T_k \oplus \bigoplus_{i=0}^{k-2} S_i \) which acts as zero on the component \( \bigoplus_{i=0}^{k-2} S_i \) and use the equality
\[
\tau_{m_1}\tau_{m_2} = \tau_{m_1}\tau_{m_2}' \quad \text{which is valid for} \ m_1, m_2 = 1, 2, \ldots, k - 1.
\]

Consider the representation of group of permutations of \( k \) elements 
\( S_k \) given by operators \( \rho_i \). Denote by \( \bar{\varepsilon} \) the image of the element
\[
\varepsilon = \frac{1}{k!} \sum_{\sigma \in S_k} \sigma
\]
of group algebra \( \mathbb{C} S_k \). Then we can expand every \( \sigma \) as a product of
operators \( \rho_i \), substitute \( \rho_i = 1 - 2\tau_i \) and represent
(3.1) \( \bar{\varepsilon} = 1 + \sum_{i,j=1}^{k-1} \tau_i x_{ij} \tau_j \) where \( x_{ij} \) are some operators.

Then put \( \pi^k_\lambda x = \bar{\varepsilon} x \) for \( x \in T_k \). Check the required properties for \( \pi^k_\lambda \). 
The property (1) follows from (3.1) and the fact that all \( \tau_i \) vanish on elements of \( S_k \). Since all images of \( \tau_i \) belong to the ideal generated
by \( \delta \omega - \lambda \), the property (2) follows. The property (3) is true since 
\( \bar{\varepsilon} = \varepsilon \rho_{i+1} \) implies \( \bar{\varepsilon} = \varepsilon(1 - \tau_{i+1}) \) and
\[
\bar{\varepsilon}(x_1 \omega x_2) = \varepsilon(1 - \tau_{i+1})(x_1 \omega x_2) = \varepsilon\pi^k_\lambda^{-1}(x_1 \delta^{-1}\lambda x_2) = \pi^k_\lambda^{-1}(x_1 \delta^{-1}\lambda x_2).
\]
The property (4) is obvious, so we have proved 

**Proposition 3.2.** The family of operators \( \pi^k_\lambda \) satisfying properties (1) - (4) exist. 

The immediate corollary is
Corollary 3.1. Every algebra $\Pi^\lambda(Q)$ is isomorphic as a filtered algebra to $S$ with multiplication law $\times^\lambda$ which polynomially depends on $\lambda$ and is such that for any homogeneous $x$ of degree $i$ and homogeneous $y$ of degree $j$ the term of degree $i+j$ in $x \times^\lambda y$ does not depend on $\lambda$.

4. Generic $\lambda$

Due to corollary 3.1 we identify $\Pi^\lambda(Q)$ with $S$ with multiplication which depends on $\lambda$ polynomially. Denote this multiplication by $\times^\lambda$. Sometimes when $\lambda$ is fixed we will omit the sign $\times^\lambda$ and simply write $xy$ instead of $x \times^\lambda y$ keeping in mind that the result depends on $\lambda$ polynomially. In this section we will prove the statement of theorems 2 and 3 for some algebraically dense subset of the set

$$\eta = \{ \lambda \in \mathbb{C}^I : \lambda \cdot \delta = 0 \}.$$ 

Namely, it will be proved for set where the following proposition holds:

**Proposition 4.1.** There exist elements $f_1, \ldots, f_n$ and $g_1, \ldots, g_n$ in $S$ and rational functions $\alpha_1, \ldots, \alpha_n$ defined on $\eta$ such that

$$\sum_{i=1}^n \alpha_i(\lambda)f_i \times^\lambda e_0 \times^\lambda g_i = 1$$

for each $\lambda$ from some algebraically dense subset of $\eta$.

**Proof.** It easily follows from the definition of deformed preprojective algebra that

$$\Pi^\lambda(Q)/\Pi^\lambda(Q) e_0 \Pi^\lambda(Q) \cong \Pi^\lambda(Q'),$$

where $Q'$ is the Dynkin diagram obtained from $Q$ by deleting vertex 0 and $\lambda'$ is the restriction of $\lambda$ to vertices of $Q'$. It was proved in [2] that deformed preprojective algebra of a Dynkin diagram is always finite dimensional and is zero for all parameters except some number of hyperplanes. We will use the following implications:

1. the homogeneous subspace $S \times^0 e_0 \times^0 S$ of $S$ has finite codimension,
2. there exists $\lambda_0 \in \eta$ such that $S \times^\lambda_0 e_0 \times^\lambda_0 S = S$.

Choose some basis in $S \times^0 e_0 \times^0 S$ of the form $(a_i \times^0 e_0 \times^0 b_i)$ where $i$ ranges over the set of positive integers and all $a_i$ and $b_i$ are homogeneous elements of $S$. It follows from the first statement that we can add some finite number of homogeneous elements of $S x_1, x_2, \ldots, x_n$ such that $x_i$ and $a_i \times^0 e_0 \times^0 b_i$ together form a basis of $S$. Now, for $\lambda \in \eta$ consider the set

$$B(\lambda) = \{ x_i | i = 1, \ldots, n \} \cup \{ a_i \times^\lambda e_0 \times^\lambda b_i | i = 1, 2, \ldots \}.$$ 

It is again a basis of $S$ because each $a_i \times^\lambda e_0 \times^\lambda b_i$ equals to sum of $a_i \times^0 e_0 \times^0 b_i$ and some terms of lower degree. Moreover every element of $S$ being expanded with respect to this basis has all coefficients polynomial in $\lambda$. 
It follows from the statement (2) that there exist some $\lambda_0$ such that for $i = 1, \ldots, n$

$$x_i = \sum_{k=1}^{K_i} f_i^k \lambda_0 \times e_0 \times g_i^k$$

where all $f_i^k$ and $g_i^k$ are elements of $S$. Consider elements $y_i(\lambda) \in S$ for $i = 1, \ldots, n$ defined by

$$y_i(\lambda) = \sum_{k=1}^{K_i} f_i^k \lambda \times e_0 \times g_i^k.$$  

Consider an $n \times n$ matrix $Z(\lambda) = (z_{ij}(\lambda))$ where $z_{ij}(\lambda)$ is the value of a coefficient near $x_i$ of the expansion of $y_j(\lambda)$ with respect to the basis $B(\lambda)$. We have the following expansion of $y_j(\lambda)$ with respect to the basis $B(\lambda)$:

$$\sum_{k=1}^{K_j} f_j^k \lambda \times e_0 \times g_j^k = \sum_{i=1}^{n} z_{ij}(\lambda) x_i + \sum_{k=1}^{L_j} c_{jk}(\lambda) a_k \times e_0 \times b_k$$

for some polynomial functions of $\lambda c_{jk}(\lambda)$. Rewrite this as

$$\sum_{i=1}^{n} z_{ij}(\lambda) x_i = \sum_{k=1}^{K_j} f_j^k \lambda \times e_0 \times g_j^k - \sum_{k=1}^{L_j} c_{jk}(\lambda) a_k \times e_0 \times b_k$$

and consider it as a system of linear equations with indeterminates $x_1, \ldots, x_n$. Clearly it can be solved for such $\lambda$ that $\det Z(\lambda) \neq 0$ and the solution will depend on $\lambda$ rationally. If we expand 1 with respect to the basis $B(\lambda)$ and then use this solution we obtain the required expansion. The set of $\lambda \in \eta$ for which $\det Z(\lambda) \neq 0$ is open. It is nonempty since $Z(\lambda_0)$ is the identity matrix, hence this set is dense. This completes the proof. □

Denote by $\eta'$ the subset of $\eta$ for which we proved the proposition above.

**Proposition 4.2.** For every $\lambda \in \eta'$ and every $x \in \mathcal{O}^\lambda(Q) = e_0 \Pi^\lambda(Q) e_0$ there exist $z(x)$ in the center of $\Pi^\lambda(Q)$ such that $e_0 z(x)e_0 = x$.

**Proof.** Put

$$z(x) = \sum_{i=1}^{n} \alpha_i(\lambda) f_i x g_i.$$  

Then

$$e_0 z(x)e_0 = \sum_{i=1}^{n} \alpha_i(\lambda) e_0 f_i x g_i e_0 = \sum_{i=1}^{n} \alpha_i(\lambda) x f_i e_0 g_i e_0 = x$$
since $\mathcal{O}^\lambda(Q)$ is commutative. Again, using commutativity of $\mathcal{O}^\lambda(Q)$ for any $y \in S$

$$yz(x) = \sum_{i=1}^{n} \alpha_i(\lambda) y f_i x g_i = \sum_{i,j=1}^{n} \alpha_i(\lambda) \alpha_j(\lambda) f_j e_0 g_j y f_i x g_i$$

$$= \sum_{i,j=1}^{n} \alpha_i(\lambda) \alpha_j(\lambda) f_j x g_j y f_i e_0 g_i = \sum_{j=1}^{n} \alpha_j(\lambda) f_j x g_j y = z(x)y.$$  

\[\square\]

**Proposition 4.3.** For every $\lambda \in \eta'$ and every $q \in I$ the algebra $e_q \Pi^\lambda(Q)e_q$ has standard identity of degree $2\delta_q$.

**Proof.** For $x \in S$ construct a $n \times n$ matrix $M(x)$ over $\mathcal{O}^\lambda(Q)$ with elements

$$m_{ij}(x) = \alpha_i(\lambda) e_0 g_i x f_j e_0.$$

Then for $x, y \in S$ the matrix $M(x)M(y)$ has elements

$$\sum_{k=1}^{n} m_{ik}(x)m_{kj}(y) = \sum_{k=1}^{n} \alpha_i(\lambda) e_0 g_i x f_k e_0 e_k(\lambda) e_0 g_k y f_j e_0$$

$$= \alpha_i(\lambda) e_0 g_i x y f_j e_0 = m_{ij}(xy),$$

so $M(xy) = M(x)M(y)$.

Denote by $p$ the matrix $M(1)$. Clearly $p$ is an idempotent and $M$ defines a homomorphism from $\Pi^\lambda(Q)$ to $p \text{Mat}(n, \mathcal{O}^\lambda(Q))p$ where $\text{Mat}(n, \mathcal{O}^\lambda(Q))$ denotes the algebra of $n \times n$ matrices over $\mathcal{O}^\lambda(Q)$. Construct an inverse map $N : \text{Mat}(n, \mathcal{O}^\lambda(Q)) \rightarrow S$. Let $A = (a_{ij})$ then put

$$N(A) = \sum_{i,j=1}^{n} \alpha_j(\lambda) f_i a_{ij} g_j.$$  

Then we can check

$$N(M(x)) = \sum_{i,j=1}^{n} \alpha_j(\lambda) f_j a_i(\lambda) e_0 g_i x f_j e_0 g_j = x$$

and

$$m_{ij}(N(A)) = \sum_{k,l=1}^{n} \alpha(i) e_0 g_i a_i(\lambda) f_k a_k g_l f_j e_0 ,$$

which implies

$$N(M(A)) = pAp.$$  

It proves that $M$ is an isomorphism. The algebra $\mathcal{O}^\lambda(Q)$ is a domain (see [2]). Hence it can be embedded into its field of fractions $F$. So the algebra $p \text{Mat}(n, \mathcal{O}^\lambda(Q))p$ can be embedded into $p \text{Mat}(n, F)p$ which is isomorphic to $\text{Mat}(r, F)$ where $r$ is the rank of $p$ in $\text{Mat}(n, F)$. Denote by $p_q$ the matrix $M(e_q)$ for $q \in I$. In a similar way $e_q \Pi^\lambda(Q)e_q$ can be embedded into $\text{Mat}(r_q, F)$ where $r_q$ is the rank of $p_q$ in $\text{Mat}(n, F)$. On the other hand $r_q = \text{tr} p_q$ which is rational function of $\lambda$. Since $r_q$ can
accept only a finite number of values, namely 1, 2, ..., n on the dense set \( \eta' \) it is constant. In \( \Pi^\lambda(Q) \)

\[
\sum_{a \in \text{Arrows}(Q)} [a, a^*] = \sum_{q \in I} \lambda_q e_q.
\]

Hence

\[
\sum_{q \in I} \lambda_q r_q = \text{tr} \sum_{q \in I} \lambda_q p_q = 0.
\]

Since this equality holds for all \( \lambda \) from \( \eta' \) which is dense in \( \eta \) there is a constant \( c \in \mathbb{C} \) such that

\[
r_q = c \delta_q
\]

for \( q \in I \). For \( q = 0 \)

\[
p_0 = M(e_0) = (\alpha_i(\lambda) e_0 g_i e_0 f_j e_0)
\]

so \( p_0 \) has rank 1. It implies \( c = 1 \) and \( r_q = \delta_q \). We have proved that the algebra \( e_i \Pi^\lambda(Q) e_i \) for \( \lambda \in \eta', q \in I \) is isomorphic to some subalgebra of the algebra of \( \delta_q \times \delta_q \) matrices over the field \( F \), so the standard identity of degree 2\( \delta_q \) is satisfied by Amitsur-Levitzki theorem. \( \square \)

5. Extending to the whole hyperplane

To finish the proof of theorems 2 and 3 we need to make several steps.

**Proposition 5.1.** For any \( \lambda \in \mathbb{C}^I \) such that \( \lambda \cdot \delta = 0 \) and any \( i \in I \) the algebra \( e_i \Pi^\lambda(Q) e_i \) satisfies the standard identity of degree 2\( \delta_i \).

**Proof.** For \( x_1, \ldots, x_{2\delta_i} \in e_i S e_i \) the sum

\[
\sum_{\sigma \in S_{2\delta_i}} \text{sign}(\sigma) x_{\sigma(1)} \lambda \times \ldots \times x_{\sigma(2\delta_i)}
\]

is zero on an algebraically dense subset of \( \lambda \in \mathbb{C}^I, \lambda \cdot \delta = 0 \). Since it is polynomial in \( \lambda \) it is zero for all \( \lambda \in \mathbb{C}^I, \lambda \cdot \delta = 0. \) \( \square \)

**Proposition 5.2.** For every \( \lambda \in \eta \) and every \( x \in \mathcal{O}^\lambda(Q) \) there exist unique \( z(x) \) in the center of \( \Pi^\lambda(Q) \) such that \( e_0 z(x) e_0 = x \).

**Proof.** First note that if such a \( z(x) \) exist then it is unique. Suppose the contrary. Then there exists \( a \) in the center of \( \Pi^\lambda(Q) \) such that \( e_0 a = 0 \). Suppose \( e_0 a \not= 0 \). Then since \( \Pi^\lambda(Q) \) is prime (see [2]) there exist \( y \in \Pi^\lambda(Q) \) such that \( e_0 y e_i a \not= 0 \). Rewrite the last as \( e_0 y e_i a \) and get a contradiction.

Then note that the degree of \( z(x) \) is not greater then that of \( x \). Let \( z(x)' \) be the term of maximal degree of \( z(x) \) and suppose that the degree of \( z(x)' \) is greater then that of \( x \). Clearly \( z(x)' \) belongs to the center of \( \Pi^0(Q) \), but \( e_0 z(x)' e_0 = 0 \) which contradicts previous remark.

The algebra \( \Pi^\lambda(Q) \) is finitely generated, and for any \( x \) since the degree of \( z(x) \) is bounded the problem of finding such \( z(x) \) for any fixed \( x \) is equivalent to some finite system of linear equations. Coefficients of the system depend on \( \lambda \) polynomially. Suppose the system has \( m \).
equations and \( n \) indeterminates. Consider the set \( W \) of \( \lambda \) for which the system has a unique solution. The system has unique solution if and only if there exist equations \( i_1, i_2, \ldots, i_n \) in the system such that the subsystem \( i_1, i_2, \ldots, i_n \) is nondegenerate (the set \( U \) of \( \lambda \) for which it is true is open) and the solution of equations \( i_1, i_2, \ldots, i_n \) satisfy other equations (the set of \( \lambda \) for which it is true is closed in \( U \)). Thus we obtain a sequence of open sets \( U_1, U_2, \ldots, U_N \) and a sequence of sets \( V_1, V_2, \ldots, V_N \) each \( V_i \) closed in corresponding \( U_i \). It follows that \( W \) is covered by \( U_1, U_2, \ldots, U_N \) and intersection of \( W \) with each \( U_i \) is closed. So \( W \) is a closed set in the union of \( U_1, U_2, \ldots, U_n \) hence it is an intersection of some open set and some closed set.

Applying proposition 4.2 together with the first remark in this proof we obtain that \( W \) is an open set. Applying proposition 5.2 with first remark we obtain that \( W \) contains some neighbourhood of zero. So for any \( x \in e_0S e_0 \) and any \( \lambda \) there exist some constant \( c \in \mathbb{C} \) such that there exist \( z'(x) \in S \) which belongs to the center of \( \Pi^\lambda(Q) \) and \( e_0 z'(x) e_0 = x \). Let \( \phi \) be a homogeneous element of degree \( k \). Define an operator \( \phi \) on \( T \) as a multiplication by \( c^\frac{k}{2} \) on each \( T_n \). Then \( \phi \) is an automorphism of algebra \( T \) and maps \( \delta \omega - c \lambda \) to \( c \delta \omega - c \lambda \). It follows that \( \phi(z'(x)) \) belongs to the center of \( \Pi^\lambda(Q) \) and \( e_0 \phi(z'(x)) e_0 = c^\frac{k}{2} x \), so \( z(x) = \phi(z'(x))c^{-\frac{k}{2}} \) belongs to the center of \( \Pi^\lambda(Q) \) and \( e_0 z(x) e_0 = x \).

**Proof of the theorem** 2. For any \( \lambda \in \mathbb{C}^I \), \( \lambda \cdot \delta = 0 \) take a map \( \phi_\lambda \) from \( \mathcal{O}^\lambda(Q) \) to the center of \( \Pi^\lambda(Q) \) such that \( e_0 \phi_\lambda(x) e_0 = x \) for all \( x \in \mathcal{O}^\lambda(Q) \). By the proposition 5.2 \( \phi_\lambda \) is uniquely defined by this property so it is linear. If \( x, y \in \mathcal{O}^\lambda(Q) \) then \( \phi_\lambda(x) \phi_\lambda(y) \) belongs to the center of \( \Pi^\lambda(Q) \) and \( e_0 \phi_\lambda(x) \phi_\lambda(y) e_0 = xy \), so again by the proposition 5.2 \( \phi_\lambda(xy) = \phi_\lambda(x) \phi_\lambda(y) \). Clearly \( \phi_\lambda(e_0) = 1 \). So \( \phi_\lambda \) is a homomorphism. The homomorphism \( \phi_\lambda \) is an inclusion because for any \( x \in \mathcal{O}^\lambda(Q) \) \( x = e_0 \phi_\lambda(x) e_0 \).

For any \( i \in I \) put \( \phi_\lambda^i(x) = e_i \phi_\lambda(x) \) for \( x \in \mathcal{O}^\lambda(Q) \). Then it is elementary to check that \( \phi_\lambda^i \) is a homomorphism from algebra \( \mathcal{O}^\lambda(Q) \) to the center of \( e_i \Pi^\lambda(Q) e_i \). It is an inclusion because \( \Pi^\lambda(Q) \) is prime (see 2), so if \( x \neq 0 \) belong to the center of \( \Pi^\lambda(Q) \) then there exist \( y \in \Pi^\lambda(Q) \) such that \( e_i y x \neq 0 \) hence \( e_i x \neq 0 \).

To prove that \( \phi_\lambda^i \) is surjective suppose that \( x \) belongs to the center of \( e_i \Pi^\lambda(Q) e_i \), \( x \) does not belong to the image of \( \phi_\lambda^i \) and has the smallest possible degree. Let \( x' \) be the term of highest degree of \( x \) (we again identify \( \Pi^\lambda(Q) \) with \( S \)). Then \( x' \) belongs to the center of \( e_i \Pi^\lambda(Q) e_i \) and thus there is homogeneous \( y \in \mathcal{O}^\lambda(Q) \) such that \( x' = \phi_\lambda^i(y) \) (it already follows from the corollary 2.4 that \( \phi_\lambda^i \) is surjective). Consider \( z = \phi_\lambda(y) \) and \( z' \) — the term of the highest degree of \( z \). Then \( z' \) is in the center of \( \Pi^\lambda(Q) \) and \( e_0 z' e_0 \) is zero or equals to \( y \). The first case is impossible due to the proposition 5.2. Thus \( z' = \phi_0(y) \) and the term of
Consider a quiver $C_n$ with $n$ vertices $I = \{1, 2, \ldots, n\}$ which form a chain:
\[
    \begin{array}{cccccccc}
    n & \xleftarrow{a_{n-1}} & n-1 & \xleftarrow{a_{n-2}} & n-2 & \cdots & \xleftarrow{a_1} & 1 \\
    \end{array}
\]
Suppose we have a sequence of complex numbers $\lambda = (\lambda_i), i = 1, \ldots, n-1$. Consider an algebra
\[
    R^\lambda_n = e_n \left( \mathbb{C}C_n/\left( \sum_{i=1}^{n-2} [a_i, a_i^*] - a_{n-1}^*a_{n-1} - \sum_{i=1}^{n-1} \lambda_ie_i \right) \right) e_n.
\]

**Proposition 6.1.** The algebra $R^\lambda_n$ is isomorphic to the algebra $\mathbb{C}[x]/P(x)$ via an isomorphism sending $x$ to $a_{n-1}a_{n-1}^*$ where $P(x)$ is a polynomial given by
\[
    P(x) = x(x + \lambda_{n-1})(x + \lambda_{n-1} + \lambda_{n-2}) \cdots (x + \sum_{i=1}^{n-1} \lambda_i).
\]

**Proof.** If $n = 1$ both algebras are isomorphic to $\mathbb{C}$. We proceed by induction. For $n > 1$ the algebra $R^\lambda_n$ splits as a vector space:
\[
    R^\lambda_n = \mathbb{C} \oplus a_{n-1}e_{n-1} \left( \mathbb{C}Q/\left( \sum_{i=1}^{n-1} [a_i, a_i^*] - a_{n-1}^*a_{n-1} - \sum_{i=1}^{n-1} \lambda_ie_i \right) \right) e_{n-1}a_{n-1}^*.
\]
Then,
\[
    e_{n-1} \left( \mathbb{C}C_n/\left( \sum_{i=1}^{n-1} [a_i, a_i^*] - a_{n-1}^*a_{n-1} - \sum_{i=1}^{n-1} \lambda_ie_i \right) \right) e_{n-1}
\]
\[
    \cong (R^\lambda_{n-1} \ast \mathbb{C}[a^*_{n-1}a_{n-1}])/\left( a_{n-2}a_{n-2}^* - a_{n-1}^*a_{n-1} - \lambda_{n-1}e_{n-1} \right),
\]
where we denote by $\ast$ the free product of algebras. By the induction hypothesis the last is isomorphic to
\[
    (\mathbb{C}[a_{n-2}a_{n-2}^*]/P^- (a_{n-2}a_{n-2}^* \ast \mathbb{C}[a_{n-1}^*a_{n-1}]))/(a_{n-2}a_{n-2}^* - a_{n-1}^*a_{n-1} - \lambda_{n-1}e_{n-1})
\]
for
\[ P^-(x) = x(x + \lambda_{n-2})(x + \lambda_{n-2} + \lambda_{n-3}) \ldots (x + \sum_{i=1}^{n-2} \lambda_i), \]
so
\[ e_{n-1} \left( C\bar{C}_n / \left( \sum_{i=1}^{n-1} [a_i, a_i^*] - a_{n-1}^* a_{n-1} - \sum_{i=1}^{n-1} \lambda_i e_i \right) \right) e_{n-1} \]
\[ \cong C[a_{n-1}^* a_{n-1}] / P^- (a_{n-1}^* a_{n-1} + \lambda_{n-1}), \]
therefore
\[ R_n^\lambda \cong C[a_{n-1} a_{n-1}^*] / (P^- (a_{n-1} a_{n-1}^* + \lambda_{n-1}) a_{n-1} a_{n-1}^*), \]
and it can be easily seen that
\[ P^- (a_{n-1} a_{n-1}^* + \lambda_{n-1}) a_{n-1} a_{n-1}^* = P(a_{n-1} a_{n-1}^*). \]

The theorem is now valid because \( e_c \Pi^\lambda(Q) e_c \) defined as in the statement of the theorem is isomorphic to the free product of algebras \( R_{\deg P_i-1}^{\lambda_i} \) factored by relation
\[ \sum_{i=1}^{n} a_{i1} a_{i1}^* = \mu e_c, \]
where
\[ \lambda_i = (\alpha_{i \deg P_i - 2} - \alpha_{i \deg P_i - 1}, \ldots, \alpha_{i1} - \alpha_{i2}, -\alpha_{i1}) \]
and by the proposition \( \ref{proposition} \) each \( R_{\deg P_i-1}^{\lambda_i} \) is isomorphic to
\[ C[a_{i1} a_{i1}^*] / P_i (a_{i1} a_{i1}^*). \]
