Almost 70% of operative procedures in North America are currently performed in an ambulatory setting. Despite advances in surgical techniques and modern methods of analgesia, 45% of patients suffer pain at home after ambulatory surgery, and moderate to severe pain intensity at home is reported by 30% of ambulatory patients. Inadequate relief of pain after ambulatory surgery increases morbidity and health care costs and reduces patients’ quality of life. To improve postoperative pain relief, an integrative approach combining pharmacologic methods and various complementary nonpharmacologic analgesic techniques has been recommended. Auricular acupuncture holds promise, as it is an easily performed technique that might be effective for treatment of both preoperative anxiety and postoperative pain in patients undergoing ambulatory surgery. However, there are reasonable doubts in the scientific community concerning the specificity of acupuncture, because the large randomized trials on auricular acupuncture for treatment of cocaine and alcohol dependence have found no difference between treatment and invasive needle control.

Thus, after refining the methodology in a pilot study, we performed a randomized controlled trial to compare the postoperative analgesic effect of auricular acupuncture with invasive needle control in patients after ambulatory knee surgery.

Methods

This prospective, patient- and evaluator-blinded, controlled study was performed between August 2003 and September 2004 at the Ambulatory Orthopedic Surgery Center of the Ernst Moritz Arndt University, Greifswald, Germany. The study was approved by the university’s ethics committee. Consecutive patients scheduled for arthroscopic ambulatory knee surgery under standardized general anesthesia were randomly assigned to receive auricular acupuncture or a control procedure. Fixed indwelling acupuncture needles were inserted before surgery and retained in situ until the following morning. Postoperative rescue analgesia was directed to achieve pain intensity less than 40 mm on a 100-mm visual analogue scale. The primary outcome measure was the postoperative requirement for ibuprofen between surgery and examination the following morning.

Results: Intention-to-treat analysis showed that patients from the control group (n = 59) required more ibuprofen than patients from the auricular acupuncture group (n = 61): median (interquartile range) 600 (200–800) v. 200 (0–600) mg (p = 0.012). Pain intensity on a visual analogue scale was similar in both groups at all time points registered. The majority of patients in both groups believed that they had received true acupuncture and wanted to repeat it in future.

Interpretation: Auricular acupuncture reduced the requirement for ibuprofen after ambulatory knee surgery relative to an invasive needle control procedure.
nonacupuncture points in addition to standard postoperative analgesia, and they provided informed consent. On the day of surgery, before induction of anesthesia, the acupuncturist randomly assigned the patients into 2 groups, using the sealed-envelope method. After the acupuncture, the acupuncturist had no further personal contact with the study patients. The group allocation was unblinded after data analysis was completed.

Auricular acupuncture was performed by 1 of 3 certified acupuncturists, including T.I.U. and T.W. (each with more than 5 years of clinical practice). Disposable fixed indwelling steel auricular acupuncture needles (0.22 mm diameter and 1.5 mm long) were inserted before surgery, fixed with skin-coloured adhesive tape and retained in situ until the following morning. The auricular acupuncture group received acupuncture at 3 acupuncture points ipsilateral to the surgery site: knee joint, shenmen and lung. Three nonacupuncture points of the helix ipsilateral to the site of surgery were used for the invasive needle control. The choice of points for auricular acupuncture and sham control has been described in detail previously.\textsuperscript{12,13}

The operations were conducted in the morning. Total intravenous anesthesia was performed according to a previously described standardized protocol,\textsuperscript{12} with monitoring of the depth of anesthesia (specifically, the bispectral index and core temperature). Incremental boluses of the weak opioid agonist piritramide (0.02 mg/kg) were administered in the anesthesia recovery room to keep the patients' reported pain intensity at less than 40 mm on a 100-mm visual analogue scale (VAS-100, where 0 = no pain and 100 = worst pain imaginable). The patients were discharged from the anesthesia recovery room according to standard discharge criteria after ambulatory surgery.\textsuperscript{14} Each patient received ibuprofen (single-dose, 200-mg tablets)
and tramadol (50-mg tablets) for postoperative pain relief and written instructions on how to take the analgesics at home. The patients were encouraged to stimulate the needles every time they experienced more pain than on discharge from the anesthesia recovery room. If the pain persisted, the patients were instructed to take single doses of ibuprofen at intervals of at least 1 hour, to a maximum of 1400 mg, until the follow-up examination. If, after taking the maximal dose, the patient was still experiencing more pain than on discharge, tramadol at 1-hour intervals, to a maximum of 200 mg, was used. During the follow-up examination at 8 am the next day, the physician-in-charge withdrew the auricular acupuncture needles and registered the amount of ibuprofen and tramadol, reported by the patient as a tablet count. The patients, the medical staff managing the patients during surgery and the physicians involved in the data collection were blinded to group allocation and had no expertise in auricular acupuncture.

The primary outcome measure was the ibuprofen requirement during the period between surgery and the follow-up examination. A variety of secondary outcome measures were also assessed. Heart rate and blood pressure were recorded before and after acupuncture, 30 minutes after tracheal intubation, 30 minutes after the end of general anesthesia and before discharge.

All statistical analyses were intention-to-treat analyses. Normally distributed numeric data were analyzed with t tests and are reported as mean and standard deviation (SD). Variables measured at multiple time points were analyzed using the repeated-measures analysis of variance. Non-normally distributed or ordinal data were compared with the Mann–Whitney test and are reported as median and interquartile range (IQR). Dichotomous data were analyzed using the $\chi^2$ test and are reported as counts with percentages. Statistical significance was assessed at $p < 0.05$. The sample size was estimated to detect a 30% difference in postoperative ibuprofen requirement, using data from the pilot study. The sample size to 46 patients for each of the 2 groups was calculated to provide 90% power with $\alpha = 0.05$. Anticipating a dropout rate of 15%, we adjusted the sample size to 60 patients per group. An additional (sensitivity) analysis, missing values for the primary outcome measure were replaced by the median of the sample.

**Results**

None of the patients in this study had previously received auricular acupuncture. Seven of the 127 patients who gave informed consent did not meet the inclusion criteria (Fig. 1). There were no differences between the study groups in demographic characteristics, duration of tourniquet application and general anesthesia, type of surgery and withdrawal rate (Table 1). Unanticipated inpatient admission (7 patients in the control group and 8 in the treatment group) caused a withdrawal rate of 12% (Fig. 1).

To achieve the target pain intensity of less than 40 mm on the VAS-100 during follow-up, the control patients required more ibuprofen than the patients who received acupuncture (median 600 mg v. 200 mg; $p = 0.012$) (Table 2). However, postoperative pain intensity scores were similar in the 2 groups at all time points registered (Fig. 2). More of the patients in the acupuncture group than in the control group required no postoperative analgesia with ibuprofen (20/52 [38%] v. 10/52 [19%], excluding patients with missing data; $p = 0.025$). Eight of the patients in the control group and 6 of those in the acupuncture group who reached the maximum daily ibuprofen dose also used tramadol ($p = 0.57$). There was a trend to discharge the patients in the acupuncture group earlier than the patients in the control group (mean difference in discharge time 15 minutes (95% confidence interval −4 to 33 minutes; $p = 0.12$) (Table 2). The amount of piritramide administered after surgery, the time from discharge until the follow-up appointment at 8 am the next day, the duration of night sleep and the number of arousals during the night after surgery were comparable (Table 2). Heart rate and blood pressure were similar in the 2 groups at all time points (data not shown). A sensitivity analysis in which the missing values for the primary outcome measure were replaced by the median of the sample yielded the comparable statistical results.

Differences in patients’ opinion concerning the success of blinding between the groups were not significant. Most patients in both groups believed that they had received true acupuncture and wanted to receive this type of therapy in the future (data not shown).

The incidence of analgesia-related side effects was similar in the 2 groups (Table 2). The incidence of perioperative bradycardia requiring atropine was higher in the control

| Characteristic | Control n = 59 | Acupuncture n = 61 |
|---------------|---------------|-------------------|
| Age, yr       | 43.8 (12.6)   | 42.0 (14.6)       |
| Body mass index, kg/m² | 28.3 (4.9) | 27.4 (5.1) |
| No. (%) women | 31 (52)       | 28 (46)           |
| Duration of tourniquet, min | 48.4 (19.6) | 50.1 (18.6) |
| Duration of anesthesia, min | 68.4 (17.5) | 71.9 (18.9) |
| Type of surgery (no. of subjects) | | |
| Diagnostic arthroscopy | 1 | 1 |
| Partial meniscus resection | 18 | 18 |
| Subtotal synovectomy | 22 | 21 |
| Meniscus refixation | 3 | 5 |
| Lateral release | 11 | 11 |
| Osteochondral autograft transfer | 2 | 4 |
| Other | 2 | 1 |

Note: SD = standard deviation.
*Except where indicated otherwise.
group, although this difference was not statistically significant (11 v. 6 patients; p = 0.22). One patient in the control group associated postoperative dizziness and nausea with acupuncture. Ten minutes after withdrawal of the needles the symptoms disappeared and the patient was discharged. Another patient in the control group reported that the needles produced localized pain at the sites of insertion and disturbed sleep. Both patients believed that they had received true acupuncture and, despite the reported problems, wanted to repeat it for perioperative complementary analgesia in the future.

**Interpretation**

We found that auricular acupuncture reduced the requirement for ibuprofen relative to invasive needle control after ambulatory arthroscopic knee surgery. The patients in both groups reported adequate pain relief, so the difference in ibuprofen requirement confirms the analgesic effect of auricular acupuncture, suggested earlier.

Since invasive needle control produces weak analgesia, the genuine clinical effect of auricular acupuncture might have been greater than reported here. The overall incidence of nausea (16/120 [13%]) was consistent with that reported in a systematic review of postdischarge symptoms (17%). The auricular acupuncture procedure was easily performed and was safe, although some patients had minor transitory complaints.

This trial confirms the findings of 2 small studies suggesting the superiority of auricular acupuncture over invasive needle control for analgesia after ambulatory surgery. Interestingly, in our pilot study the ibuprofen requirement in both groups was higher than in the present investigation, probably because of a higher rate of painful arthroscopic procedures. A potentially painful lateral release procedure was performed in 7 (39%) of 18 patients in the pilot study but only 22 (18%) of 120 in the present investigation. The withdrawal rate of 12% in the present study can be explained by the time of randomization, before general anesthesia.

The study protocol was based on expert recommendations, which follow CONSORT (Consolidated Standards of Reporting Trials) guidelines with specific requirements for acupuncture studies. The routine general anesthesia procedure, with monitoring of depth of anesthesia and patients’ core temperature, was performed to minimize the influence of intraoperative factors on postoperative pain.

### Table 2: Postoperative outcomes and adverse events

| Outcome or event                          | Control n = 59 | Acupuncture n = 61 | p value  |
|------------------------------------------|----------------|-------------------|----------|
| Ibuprofen requirement, mg, median (IQR) | 600 (200–800)  | 200 (0–600)       | 0.012    |
| Patients needing tramadol                | 8 (14)         | 6 (10)            | 0.57     |
| Piritramide dose in ARR, mg, mean (SD)   | 7.6 (3.7)      | 7.7 (3.5)         | 0.91     |
| Discharge time from ARR, min, mean (SD)  | 134 (50)       | 119 (42)          | 0.12     |
| Follow-up time, h, mean (SD)             | 18.1 (1.9)     | 17.8 (1.9)        | 0.34     |
| Night sleep after surgery, h, mean (SD)  | 5.4 (2.2)      | 5.8 (1.8)         | 0.37     |
| No. of night arousals after surgery, median (IQR) | 3 (1–4) | 2 (1–3) | 0.35 |

**Adverse events**

**Related to analgesia**

- Somnolence in ARR: 14 (24) vs. 10 (16); p = 0.33
- Nausea on discharge: 3 (5) vs. 3 (5); p = 0.92
- Nausea between surgery and follow-up appointment: 9 (15) vs. 7 (11); p = 0.74
- Vomiting: 0 vs. 2 (3); p = 0.16
- Dizziness, hypotonia: 2 (3) vs. 1 (2); p = 0.51
- Perioperative bradycardia: 11 (19) vs. 6 (10); p = 0.22

**Related to acupuncture**

- Local pain: 1 (2) vs. 0; p = 0.30
- Dizziness, nausea: 1 (2) vs. 0; p = 0.30

Note: IQR = interquartile range, ARR = anesthesia recovery room, SD = standard deviation.

perioperative medical staff and evaluators were blinded to group allocation to minimize potential bias. The patients had similar lesions and operative procedures and hence were expected to have a similar level of pain; we were therefore able to use standardized instead of individualized auricular acupuncture, which assured the methodological quality of the trial.22

The requirement for analgesia during a period of at least 24 hours after surgery, which has been recommended as one of the optimal measures for acute pain,23 was the primary outcome measure in the present study. If all patients receive analgesic medication ad libitum and report adequate pain relief, this is a reliable and ethical method to assess pain relief. Although the patients were successfully blinded to group assignment, self-reporting of the amount of analgesics taken (the primary outcome measure) may represent a study limitation.

The specificity of the acupuncture points has for decades been a crucial question in trials examining the effectiveness of acupuncture.9 The standard control procedure — intradermal insertion of needles in non-acupuncture (sham) points — stimulates the neural pathways of diffuse noxious inhibitory control.24 Under clinical conditions, invasive needle control was reported to have an analgesic effect in 40% to 50% of patients, whereas true acupuncture had this effect in 70% of patients.10 We restricted our study to 2 groups, true acupuncture and sham acupuncture, and questions about the extent of the genuine clinical and placebo (purely psychological) effects of auricular acupuncture remain beyond the scope of our study. Given the cost of treating the side effects of commonly used nonopioid analgesics,5 determining the cost-effectiveness of auricular acupuncture might be an interesting question for a future trial.

In conclusion, this study has shown that auricular acupuncture applied to specific acupuncture points reduced the requirement for ibuprofen relative to invasive needle control after ambulatory arthroscopic knee surgery. To assess the genuine clinical effectiveness of auricular acupuncture, this method must now be compared with standard therapy.
