Abstract

It is shown that almost all features of the quark and lepton masses can be satisfactorily and simply explained without family symmetry, including the threefold mass hierarchy among the generations, and the relations $m_\tau \approx m_b$, $m_\mu \approx 3m_s$, $m_e \approx \frac{1}{3}m_d$, $m_u/m_t \ll m_d/m_b$, $\tan \theta_c \approx \sqrt{m_d/m_s}$, $V_{cb} \ll \sqrt{m_s/m_b}$, and $V_{ub} \sim V_{cb}V_{us}$. Various aspects of the group theory of SO(10) play an essential role in explaining these relations. The form of the mass matrices, rather than being imposed arbitrarily, emerges naturally from a simple structure at the unification scale. This structure involves only vector, spinor and adjoint representations. There are distinctive and testable predictions for $\tan \beta$ and the neutrino mixing angles.

*Supported in part by Department of Energy Grant #DE-FG02-91ER406267
In this Letter we show that the group theory of $SO(10)$ can provide a satisfactory explanation of almost all of the features of the quark and lepton masses and mixing angles\textsuperscript{1} without family symmetry. We propose a model, in two versions, each of which has several testable consequences for neutrino mixing angles and for the parameter $\tan \beta$.

We propose that the pattern of fermion masses is determined by the following Yukawa terms in the superpotential\textsuperscript{2}.

\[
W = M(\overline{16} \ 16) + \sum_{i=1}^{3} b_i (16, \overline{16}) 45_H + \sum_{i=1}^{3} a_i (16, 16) 10_H \\
+ d(10 \ 10') 45^{(X)}_H + \sum_{i=1}^{3} c_i (16, 10) 16_H + \sum_{i=1}^{3} c'_i (16, 10') 16_H.
\]

(1)

In addition to the three ordinary families of quarks and leptons, which are contained in the spinors denoted $16_i$, there is a pair of spinor and antispinor $(16, \overline{16})$, and a pair of vectors $(10, 10')$. The Higgs supermultiplets are distinguished by the subscript ‘$H$’. We will henceforth call the first three terms of eq.(1) $W_{\text{spinor}}$ and the last three terms $W_{\text{vector}}$.

It will be shown that this simple structure explains the following nine well-known features of the quark and lepton spectrum.

*The hierarchy:*

(I) The first generation is much lighter than the second and third.

(II) The second generation is much lighter than the third.

*The mass ratios:*

(III) $m_0^q \cong m_0^c$ (see Ref. 3). [The superscript $^0$ refers throughout to quantities at the unification scale.]

(IV) $|m_\mu/m_s^0| \cong 3$.

(V) $|m_\mu/m_s^0| \cong |m_\mu/m_s^0|^{-1} \cong \frac{1}{3}$. (The Georgi-Jarlskog relations.\textsuperscript{4})
(VI) $m_\mu^0/m_t^0 \ll m_d^0/m_b^0$ and $m_c^0/m_t^0$. ($10^{-5}$ versus respectively $10^{-3}$ and $0.3 \times 10^{-3}$.)

The mixing angles:

(VII) $V_{cb}$ is small compared to $\sqrt{m_d^0/m_b^0}$.

(VIII) $\tan \theta_c \approx \sqrt{m_d^0/m_s^0}$ (see Ref. 5).

(IX) $V_{ub} \sim V_{cb} V_{us}$.

In understanding the structure of eq.(1) a crucial point is that there is no Yukawa term $\sum_{i,j=1}^3 f_{ij} (16_i 16_j) 10_H$ coupling the ordinary families to each other, for the coefficient of such a term, $f_{ij}$, would be a matrix in ‘family space’, and one would naturally expect the three eigenvalues of such a matrix to be all of the same order rather than to exhibit a hierarchical pattern as observed in nature. Instead, what happens in this model is that the families $(16_i)$ couple to each of the ‘extra’ fermion multiplets $(16, \overline{16}, 10, 10')$ with Yukawa couplings that are vectors in family space $(a_i, b_i, c_i, c'_i)$. This leads, to first approximation, as will be seen, to a ‘factorized’ form for the mass matrices, $M_{ij} \sim a_i b_j$, which because it has rank less than three does produce a hierarchy.

Another role played by the ‘extra’ fermions is to allow the $45_H$, which breaks $SO(10)$, to couple directly to the quarks and leptons as it could not renormalizably do were there only the ordinary families, $16_i$. This is important because some of the predictions of minimal $SO(10)$, such as $m_\mu^0 = m_s^0$ and $m_c^0/m_t^0 = m_s^0/m_b^0$, are badly broken in nature.

We will also discuss a variant of this model which is obtained by adding
to the superpotential of eq. (1) the following piece.

\[ W_{\text{adjoint}} = f(45 \ 45')45_H + \sum_{i=1}^{3} e_i(16, 45)\mathbf{16}_H + \sum_{i=1}^{3} e'_i(16, 45')\mathbf{16}_H. \]  

(2)

The structure of this set of terms is quite analogous to \( W_{\text{spinor}} \) and \( W_{\text{vector}} \). Here the ‘extra’ fermions are adjoints \((45, 45')\) which couple, as before, to the ordinary families with coefficients which are vectors in family space \((e_i, e'_i)\). Note that because the Higgs fields \(45(X)H\) and \(45'H\) are antisymmetric tensors, the \(10\) and \(10'\) in \( W_{\text{vector}} \) must be distinct, as must the \(45\) and \(45'\) in \( W_{\text{adjoint}} \).

We will denote the mass matrices of the quarks and leptons by \(U\), \(D\), \(L\), \(N\), and \(M_R\). More precisely, \( W_{\text{mass}} = \sum_{i,j=1}^{3}[u^c_{Li}U_{ij}u_{Lj} + d^c_{Li}D_{ij}d_{Lj} + l^c_{Li}l_{Lj} + \nu^c_{Li}\nu_{Lj} + \nu^c_{Li}(M_R)_{ij}\nu^c_{Lj}] \). The dominant contributions to these matrices are assumed to come from \( W_{\text{spinor}} \) and have the exact form\(^8\) (up to terms of order \( M_W/M_{\text{GUT}} \sim 10^{-14} \))

\[ U_0 = aTv \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & Q_u \sin \theta/N_u (Q_u + Q_u) \cos \theta/N_u N_u \end{pmatrix}, \]  

(3)

\[ D_0 = aTv' \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & Q_d \sin \theta/N_d (Q_d + Q_d) \cos \theta/N_d N_d \end{pmatrix}, \]  

(4)

\[ L_0 = aTv' \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & Q_{l+} \sin \theta/N_{l+} (Q_{l+} + Q_{l-}) \cos \theta/N_{l+} N_{l+} \end{pmatrix}, \]  

(5)

\[ N_0 = aTv \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & Q_{\nu} \sin \theta/N_{\nu} (Q_{\nu} + Q_{\nu}) \cos \theta/N_{\nu} N_{\nu} \end{pmatrix}. \]  

(6)

Here \( \theta \) is the angle between the Yukawa coupling constant vectors \( a_i \) and \( b_i \) appearing in eq. (1), and \( a \) and \( b \) are their lengths. \( Q \) is an \( SO(10) \) generator\(^9\)
giving the direction in group space of the vacuum expectation value (VEV) of the adjoint Higgs field, \(45_H\),

\[
\langle 45_H \rangle = \Omega Q, \quad (7)
\]

and \(Q_f\) is the \(Q\) charge of the fermion \(f\). \(\Omega\), like \(M\), is of order \(M_{GUT}\), so that we define a dimensionless ratio \(b\Omega/M \equiv T\) which is of order unity. The \(N_j\) are defined by \(N_j \equiv \sqrt{1 + T^2 |Q_f|^2}\). (These factors of \(N_j\) do not play a significant role in what follows. For \(T < 1\) they are close to one. We keep them for the sake of exactness.) Finally, \(v\) and \(v'\) are the usual \(SU(2)_L \times U(1)_Y\)-breaking VEVs of the \(5(10_H)\) and \(\bar{5}(10_H)\) respectively. (Throughout ‘\(p(\mathbf{q})\)’ denotes a \(p\) of \(SU(5)\) contained in a \(q\) of \(SO(10)\).)

The exact forms given in eqs.(3) – (6) can be simply derived by straightforward algebra, but can be more easily understood from Fig. 1.
By inspection, that diagram gives the expression

\[
W_{\text{mass}} = \sum_{i,j=1}^{3} a_i b_j \frac{\langle 10_H \rangle \langle 45_H \rangle}{M} (16,16_j);
\]  

(8)

or \( W_{\text{mass}} = aT \langle 10_H \rangle (\sum_{i=1}^{3} \hat{a}_i 16_i) (\sum_{j=1}^{3} \hat{b}_j Q_{16} 16_j) \), where \( \hat{a}_i \equiv a_i/a \), \( \hat{b}_i \equiv b_i/b \). For the up quarks this gives

\[
W_{\text{mass}}^{up} = aT v \sum_{i,j=1}^{3} [\hat{a}_i \hat{b}_j Q_u + \hat{a}_j \hat{b}_i Q_{uc}] u^c_i u_j,
\]  

(9)

with similar expressions for the down quarks and leptons. Without any loss of generality one may choose the axes in family space so that

\[
\hat{a}_i = (0, \sin \theta, \cos \theta),
\]

\[
\hat{b}_i = (0, 0, 1),
\]  

(10)

which when substituted into eq.(9) and its analogues gives the matrices displayed in eqs.(3) – (6) with \( N_f = 1 \). (To build up the factors \( N_f^{-1} \) one must sum over all tree graphs with arbitrary numbers of superheavy mass or VEV insertions. More simply one can just do the algebra of integrating out the 16 and \( \overline{16} \).

Because \( \langle 45_H \rangle \) cannot break the Standard Model gauge group, \( Q \) must be a linear combination of the hypercharge and the \( SU(5) \)- singlet generator, \( X \). \( (SO(10) \supset SU(5) \times U(1)_X) \). For convenience \( Q \) will be normalized so that

\[
Q = (\frac{-1}{3})X + (\frac{6}{5} \epsilon) \frac{Y}{2} = 2 I_{3R} + (\frac{6}{5} \epsilon) \frac{Y}{2},
\]  

(11)

where \( X \) is normalized conventionally, so that \( X_{10(16)} = 1 \), \( X_{5(16)} = -3 \), \( X_{1(16)} = 5 \); and \( \epsilon \equiv z - 1 \). Thus, for the fermions contained in the 16 of
\[ Q_u = Q_d = \frac{1}{5}\epsilon, \quad Q_{u^c} = -1 - \frac{4}{5}\epsilon, \quad Q_{d^c} = 1 + \frac{2}{5}\epsilon \]
\[ Q_{l^-} = Q_{\nu^c} = -\frac{3}{5}\epsilon, \quad Q_{l^+} = 1 + \frac{6}{5}\epsilon, \quad Q_{\nu^c} = -1. \]

We shall assume, for reasons that will become apparent shortly, that \( Q \) is oriented approximately in the \( I_{3R} \) direction; that is, that \( |\epsilon| \ll 1 \). Then it is seen from their definitions that the \( N_f \) for all the left-handed fermions \((u, d, l^-, \nu)\) are very close to one, while for all the left-handed anti-fermions \((u^c, d^c, l^+, \nu^c)\) \( N_f \approx \sqrt{1 + T^2} \equiv N \).

Several striking features of the mass matrices in eqs.(3) – (6) are evident upon inspection.

As a consequence of factorization (cf. eq.(9)) the mass matrices are rank 2. This explains (I), the lightness of the first generation. Also explained is (III), \( m^0_b \cong m^0_\tau \). The origin of this relation is the fact that \( D_{33} \cong aT\varphi'(Q_{d^c} + Q_d)\cos\theta/N = aT\varphi'(Q_{l^+} + Q_{l^-})\cos\theta/N \cong L_{33} \). The equality of these expressions is no accident, but a consequence of the fact that \( l^+ l^- \) and \( d^c d \) both couple to the same Higgs doublet, \( \varphi' \), and thus must have equal charges. On the other hand, eqs.(4) and (5) show that \( |m^0_{\mu}/m^0_s| \neq 1 \) but rather
\[ \left| \frac{m^0_{\mu}}{m^0_s} \right| \cong \left| \frac{m^0_{\mu}m^0_{\mu^*}}{m^0_s m^0_s^*} \right| = \left| \frac{\det_{23} L}{\det_{23} D} \right| \cong \left| \frac{Q_{l^+} Q_{l^-}}{Q_{d^c} Q_d} \right| = 3 \left| \frac{1 + 6\epsilon/5}{1 + 2\epsilon/5} \right|. \]

Thus the empirical relation (IV), \( m^0_{\mu}/m^0_s \cong 3 \) is seen to follow if \( Q \) is approximately in the \( I_{3R} \) direction; that is, if \( |\epsilon| \ll 1 \). (Cf. eq.(11).)

The \( I_{3R} \) direction is a natural one for the vacuum expectation value of a
Higgs field in the adjoint representation of $SO(10)$. For example,\textsuperscript{10} the superpotential $-\mu tr(A^2) + \lambda tr(A^4)$, where $A$ is a $45$, only has $SU(3) \times SU(2) \times U(1)$-invariant solutions in the $I_{3R}$, $B - L$, and $X$ directions. Other interesting superpotentials\textsuperscript{11} give the same possibilities. As evidence that adjoint Higgs might well have potentials of this type, it is significant that the Dimopoulos-Wilczek mechanism\textsuperscript{12}, which is necessary to solve the ‘doublet-triplet splitting problem’ in $SO(10)$ requires the existence of an adjoint Higgs whose vacuum expectation value is in the $B - L$ direction.

The assumption that $Q$ is approximately in the $I_{3R}$ direction would also provide a group-theoretical explanation for two other facts, (II) and (VII). (II), that the second generation is much lighter than the third, can be seen from eqs.(3) – (6), which reveal that the $(2,3)$ elements of all the matrices vanish as $\epsilon \to 0$, causing the matrices to become rank 1. For example, $m^0_s/m^0_b \simeq N \epsilon \sin^2 \theta$. That (VII), $V^0_{cb}$ is small compared to $\sqrt{m^0_s/m^0_b}$, follows from $V^0_{cb} \simeq \tan^{-1}(U_{32}/U_{33}) - \tan^{-1}(D_{32}/D_{33}) \simeq \frac{2}{5} \epsilon \sin \theta \cos \theta$. In the $\epsilon \to 0$ limit both $V^0_{cb}$ and $V^0_{cb}/\sqrt{m^0_s/m^0_b} \simeq \sqrt{4\epsilon/5N} \cos \theta$ vanish. It is well-known that Fritzsch-type relations\textsuperscript{13} for $V^0_{cb}$ such as $|V^0_{cb}| = |\sqrt{m^0_s/m^0_b} - e^{i\alpha} \sqrt{m^0_c/m^0_t}|$ fail even though the analogous relation for the Cabibbo angle works well, because the observed $V^0_{cb}$ is about a factor of three too small. Here that smallness is explained as due to the smallness of $\epsilon$.

There is one potentially troubling feature of the forms given in eqs.(3) – (6) and that is that in the small $\epsilon$ limit the bad ‘proportionality’ prediction of naive $SO(10)$, namely $m^0_c/m^0_t \simeq m^0_s/m^0_b$, holds. The violation of this relation will be explained in an interesting way below.

Taking into account the heretofore neglected terms $W_{vector}$ one can show
that the exact mass matrices (up to terms of order \( M_W/M_{GUT} \sim 10^{-14} \)) coming from eq.(1) are (using eq.(12))

\[
U = U_0 = aTv \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & \frac{1}{5} \epsilon \sin \theta / N_u \\
0 & -(1 + \frac{4}{5} \epsilon) \sin \theta / N_{u^c} & -(1 + \frac{3}{5} \epsilon) \cos \theta / N_{u^c} N_{u^c}
\end{pmatrix},
\]

(14)

\[
D = aTv' (I + \Delta_{d^c})^{-\frac{1}{2}} \begin{pmatrix}
0 & -c_{12} & -c_{13} / N_d \\
c_{12} & 0 & \left( \frac{2}{5} \epsilon \sin \theta - c_{23} \right) / N_d \\
c_{13} / N_{d^c} & \left( 1 + \frac{2}{5} \epsilon \right) \sin \theta / N_{d^c} & \left( 1 + \frac{3}{5} \epsilon \right) \cos \theta / N_{d^c} N_{d^c}
\end{pmatrix},
\]

(15)

\[
L = aTv' \begin{pmatrix}
0 & c_{12} & -c_{13} / N_{l^+} \\
-c_{12} & 0 & \left( -\frac{2}{5} \epsilon \sin \theta + c_{23} \right) / N_{l^+} \\
-c_{13} / N_{l^+} & \left( 1 + \frac{6}{5} \epsilon \right) \sin \theta / N_{l^+} & \left( 1 + \frac{4}{5} \epsilon \right) \cos \theta / N_{l^+} N_{l^+}
\end{pmatrix} (I + \Delta_{l^+}^T)^{-\frac{1}{2}},
\]

(16)

\[
N = N_0 = aTv \begin{pmatrix}
0 & 0 & 0 \\
0 & 0 & -\frac{2}{5} \epsilon \sin \theta / N_{\nu^c} \\
0 & -\sin \theta / N_{\nu^c} & -(1 + \frac{3}{5} \epsilon) \cos \theta / N_{\nu^c} N_{\nu^c}
\end{pmatrix}.
\]

(17)

One sees that \( U_0 \) and \( N_0 \) are unaffected by adding \( W_{vector} \) and that the effect on \( D_0 \) and \( L_0 \) is to add to them an antisymmetric piece, \( c_{ij} \), and to multiply them by mixing matrices \( (I + \Delta)^{-\frac{1}{2}} \). For the moment we will assume that these factors can be neglected as would be the case if \( \Delta_{d^c}, \Delta_{l^+} \ll 1 \), although such matrices will play an important role in our later discussion.

(Their exact forms are given by \( (\Delta_{d^c})_{ij} = \left| \frac{\langle 1 | (16)_{ij} | 0 \rangle}{\langle d^c | (45)_{ij} | N_d \rangle} \right|^2 p_i p_j \epsilon \ell_i c_j + c_i \epsilon \ell_j c_j \) where \( \vec{p} \equiv (1, 1, N_{d^c}^{-1}) \) and the same for \( \Delta_{l^+} \) with \( N_{d^c} \) replaced by \( N_{l^+} \).) The origin of the antisymmetric pieces, \( c_{ij} \), can be understood from Fig. 2.
By inspection of that diagram one sees that $W_{\text{vector}}$ contributes

$$\Delta W_{\text{mass}} = \sum_{i,j=1}^{3} (c_i c'_j - c'_i c_j) \frac{\langle 1(16_H) \rangle \langle 5(16_H) \rangle}{d \langle 45^{(X)}_H \rangle} 10(16_i) \bar{5}(16_j).$$

The antisymmetry in flavor is due to the antisymmetry of the adjoint of $SO(10)$. Under the interchange of $10$ and $10'$ in Fig.2 the diagram changes sign and $ij \rightarrow ji$. Comparing with eqs.(15) and (16) one obtains $c_{ij} = (c_i c'_j - c'_i c_j) \frac{M(1(16_H))}{abd(45^{(X)}_H) \langle 5(16_H) \rangle} \frac{\langle 5(16_H) \rangle}{\langle 5(10_H) \rangle}$. We assume that the vacuum expectation value of the $45^{(X)}_H$ is in the $X$ direction so that the antisymmetric pieces added to $D$ and $L$ are the same. The smallness of the $c_{ij}$ can come from the smallness of the $c_i$ or $c'_i$, or of their cross product, or of the ratios of vacuum expectation values.

The forms of the full matrices exhibited in eqs.(14) – (17) now explain the several further relationships (V), (VI), and (VIII). Relation (V), that $|m_e^0/m_d^0| \cong |m_u^0 m_b^0/m_\mu^0 m_\tau^0| \cong 1/3$, is a consequence of $\det D = \det L$, which,
it should be noted, is an exact relation for any values of the parameters both in the limit $\Delta \to 0$ and in the limit $N_f \to 1$ (which makes $\Delta_{e^-} = \Delta_{\ell^-}$).

Relation (VI), that $m_u^0$ is proportionately very tiny compared to $m_d^0$ and $m_e^0$, comes from the fact that $W_{\text{vector}}$ contributes only to $D$ and $L$ and leaves $U$ rank 2, and thus $u$ massless. Some higher order effects presumably give a small mass to $u$, but as these contributions to $U$ would typically be of order $10^{-5} a T v$ one would expect them to have a negligible effect on everything else besides $m_u$. (For example, their contribution to the Cabibbo angle would typically be of order $m_u/m_c \sim 0.005$.)

Relation (VIII), $\tan \theta_c \approx \sqrt{m_d^0/m_s^0}$ is famously successful. In schemes of the Fritzsch type there is an extra contribution $e^{i \alpha} \sqrt{m_u^0/m_e^0}$, which, being of magnitude $0.07 \approx \frac{1}{3} \tan \theta_c$ requires that the phase $\alpha$ take a particular value to obtain numerical agreement. Here, because $W_{\text{vector}}$ does not contribute to $U$, one avoids that extra term.

The foregoing three relations are consequences of the facts that $W_{\text{vector}}$ only contributes to $D$ and $L$ (required for (VI) and (VIII)) and that its contribution is antisymmetric (required for (V) and (VIII)). But it should be emphasized that these facts in turn are consequences of aspects of $SO(10)$ group theory: namely, that the vector representation contains only down quarks and leptons, and that the adjoint representation is antisymmetric.

The final relation, (IX), $V_{ub} \sim V_{cb} V_{us}$, follows if one makes the natural assumption that all the $c_{ij}$ are of the same order, since $V_{ub} \sim c_{13}/m_b^0$, $V_{us} \sim c_{12}/m_s^0$, and $V_{cb} \sim m_s^0/m_b^0$. This assumption also would imply that $c_{23}$ plays a negligible role. So far, then, there are seven relevant combinations of parameters: $aT v$, $v/v'$, $\sin \theta$, $\epsilon$, $c_{12}$, $c_{13}$, and $N$. (And for small $T$, $N \approx 1$.
and plays no role.)

Now comes the question of why \((m_0^c/m_1^0)/(m_0^b/m_0^b) \lesssim \frac{1}{5}\), when according to naive \(SO(10)\) and eqs.\((3), (4), \) and \((12)\) it ought to be approximately equal to unity. There are two possible simple answers, that \(m_0^b\) or \(m_0^c\) is suppressed, and they lead to the two versions of the model referred to earlier. The first version, where \(m_0^b\) is suppressed, has greater economy as it makes do with only the terms in eq\.(1). In this version the factor \((I + \Delta d c)^{-\frac{1}{2}}\) which multiplies \(D_0\) on the left in eq\.(15) is assumed to have the approximate form \(\text{diag}(1, 1, \delta)\) where \(\delta \lesssim \frac{1}{3}\). Then \(m_0^b \simeq (D_{32}^2 + D_{33}^2)^{\frac{1}{2}}\) gets multiplied by \(\delta\), while \(m_0^s \simeq D_{23}D_{32}/D_{33}\) is left unaffected. While this works, it turns out to have some minor drawbacks. The angle \(\theta\) ends up being somewhat small, and, furthermore, for \((I + \Delta d c)^{-\frac{1}{2}}\) to have the desired form the vector \(c_i\) (or alternatively \(c'_i\)) must also be nearly aligned with \(b_i\). Such a preferred direction in family space is somewhat unappealing since family symmetry has been eschewed. A second drawback is that \(m_0^b \simeq m_0^\tau\) is no longer automatic but must be fit. Aside from this, this version of the model preserves the explanatory successes \((\text{I}) - (\text{IX})\) and has in addition several interesting predictions.\(^{15}\)

\[
\begin{align*}
\tan \beta & \simeq \frac{v/v'}{m_0^c/m_0^s}, \\
|\theta_{\nu\mu}| & \simeq \sqrt{m_0^c/m_0^\mu} + \frac{1}{2} \tan \theta[\Re(\theta_{\nu\tau})/(1 + |\theta_{\nu\tau}|^2)], \quad (19)
\end{align*}
\]

Note that since the ratio \(m_1^0/m_b^0\) has been affected by the factor \((I + \Delta d c)^{-\frac{1}{2}}\), \(\tan \beta\) is given by the (unaffected) ratio \(m_0^c/m_0^s\), which is quite a distinctive prediction. The largeness of \(\theta_{\nu\tau}\) arises because \(L_{32}/L_{33}\) is no longer \(\simeq \tan \theta\) but (a careful calculation shows) \(\simeq \frac{1}{2} \delta^{-1} \tan \theta\), whereas \(N_{32}/N_{33} \sim \tan \theta\).
We shall now discuss the second and in some ways cleaner version of the model, in which $m_0^c$ is suppressed. We shall see that if the terms $W_{\text{adjoint}}$ given in eq.(2) are added to the superpotential then the ratio $m_0^c/m_0^t$ is typically suppressed relative to $m_0^s/m_b^0$ by a factor of $O(\epsilon)$ without any special alignment of vectors in family space or special values of parameters. In other words, the smallness of $m_0^c/m_0^t$ has a group-theoretical origin. This suppression is achieved by a matrix $(I + \Delta_{u^c})^{-\frac{1}{2}}$ appearing in eq.(14) analogous to the matrices appearing in eqs.(15) and (16).

Since $\langle 1(16_H) \rangle \neq 0$ and is $O(M_{\text{GUT}})$, $W_{\text{adjoint}}$ causes the $10(16_i)$ to mix with the $10(45')$ so: $\mathbf{16}(45') [f\Omega Q_{10(45)}10(45) + \langle 1(16_H) \rangle e_i 10(16_i)]$, with similar mixing of $10(16_i)$ and $10(45')$ caused by the $e_i$ term. In particular, since the $10(16_i)$ contains the $u^c_i$ there will be produced in eq.(14) a mixing matrix $(I + \Delta_{u^c})^{-\frac{1}{2}}$ multiplying $U_0$ on the left, with $\Delta_{u^c}$ given by

$$\Delta_{u^c} = \frac{|\langle 1(16_H) \rangle|^2}{f\Omega Q_{u^c(45)}} \left[ E^*_i E_j + E'^*_i E'_j \right],$$

(20)

where $E_i \equiv p_i e_i$, $E'_i \equiv p_i e'_i$, and $p_i \equiv (1, 1, N_{u^c}^{-1})$. (Compare with the expression for $\Delta_{d^c}$ given earlier.) Since the $10(16_i)$ also contains the $u_i$, $d_i$, and $l_i^+$, there will be analogous mixing matrices $(I + \Delta_u)^{-\frac{1}{2}}$, $(I + \Delta_d)^{-\frac{1}{2}}$, and $(I + \Delta_{l^+})^{-\frac{1}{2}}$ introduced in the obvious places in eqs.(14) – (16), where $\Delta_u$, $\Delta_d$, and $\Delta_{l^+}$ are given by eq.(20) with $Q_{u^c(45)}$ being replaced by $Q_{u(45)}$, $Q_{d(45)}$, and $Q_{l^+(45)}$, respectively, and $N_{u^c}$ replaced by the appropriate $N$’s.

What is required to suppress $m_0^c/m_0^t$ is that at least some elements of $\Delta_{u^c}$ should be quite large, whereas to preserve the successful relations (I) – (IX) the elements of $\Delta_u$, $\Delta_d$, and $\Delta_{l^+}$ should be somewhat (but not necessarily very much) smaller than unity. The required largeness of $\Delta_{u^c}$ is explained
rather elegantly by group theory. The crucial point is that the \(Q_{u^c(45)}\) appearing squared in the denominator of eq.(20) is *not* the \(Q\) charge given in eq.(12) of the \(u^c_i\) that is contained in the \(16_i\). Rather, it is the \(Q\) charge of the \(u^c\) that are contained in the \(45\) and \(45'\). The difference is that \(X_{10(45)} = -4\), whereas \(X_{10(16)} = 1\), so that by eq.(11) \(Q_{10(45)} = Q_{10(16)} + 1\). From eq.(12), then, one sees that \(Q_{u^c(45)} = -\frac{4}{3} \, \epsilon\), and therefore \(\Delta_{u^c} \propto (\frac{1}{3} \, \epsilon)^2\). The expressions for \(\Delta_{u}, \Delta_{d}, \) and \(\Delta_{l+}\), on the other hand, have in their denominators 

\[Q^2_{u(45)} = Q^2_{d(45)} = (1 + \frac{1}{5} \, \epsilon)^2\] 

and consequently are not enhanced.

It might be thought that some special form of \(\Delta_{u^c}\) might have to be assumed to get a suppression of \(m^0_c/m^0_l\). Curiously, owing to the rank-2 nature of \(\Delta_{u^c}\), this is not so. Generically, with the elements of \(\Delta_{u^c} = O(\frac{1}{3} \, \epsilon)\) and given by eq.(20), \((I + \Delta_{u^c})^{-\frac{1}{2}}\) suppresses \(m^0_c/m^0_l\) by a factor \(O(\epsilon)\). More precisely, if \(|\vec{E}| \sim |\vec{E}'| > \epsilon\), then 

\[
\left(\frac{m^0_c}{m^0_l}\right)/(\frac{m^0_s}{m^0_b}) \approx \frac{4}{5} \, \epsilon \left|\frac{f_{\Omega}}{(1(16_u))}\right| \frac{|\vec{E} \times \vec{E}'|[E^2 + (E')^2]^{\frac{1}{2}}}{(|E \times E'|)^{3/2}} = O(\epsilon).
\]

It is assumed that while \(\langle 1(16_H)\rangle\) is non-zero and superlarge, \(\langle 5(16_H)\rangle\) vanishes. This condition can be naturally achieved\(^{16}\) and means that \(W_{\text{adjoint}}\) will contribute no antisymmetric piece to \(U_0\). The only effect, then, of \(W_{\text{adjoint}}\) is the suppression of \(m^0_c/m^0_l\). All the successful relations (I) – (IX) remain essentially untouched. In particular, the effect of \((I + \Delta_{u^c})^{-\frac{1}{2}}\) on \(V^0_{cb}\) is to make 

\[V^0_{cb} \approx \frac{2}{5} \, \epsilon \sin \theta \cos \theta \left[1 + \frac{N}{2} \tan \theta \left(\frac{f^2}{f}\right) \right].\]

This version of the model has the following predictions.

\[
\begin{align*}
\tan \beta &\approx \frac{v}{v'} \equiv \frac{m^0_t}{m^0_b}, \\
\theta_{e\mu} &\approx \frac{\sqrt{m^0_b/m^0_\mu} + O(m^0_\mu/m^0_c)}{m^0_\mu/m^0_\mu}, \\
\theta_{e\tau} &\approx V_{ub} + O(m^0_\mu/m^0_\mu).
\end{align*}
\]

(21)
\( \theta_{\mu\tau} \) gets a large contribution from \( L_{32}/L_{33} \cong \tan \theta \sim 1 \), and can therefore be very large. But for a wide range of the parameters describing \( M_R \), the Majorana mass matrix of the right-handed neutrinos, \( \theta_{\mu\tau} \cong 3V_{cb} \) (see Ref. (17)) due to the near cancellation between \( L_{32}/L_{33} \) and \( N_{32}/N_{33} \). More precisely,

for \( (M_R^{-1})_{22} \leq (M_R^{-1})_{23} \leq (M_R^{-1})_{33} \), \( \theta_{\mu\tau} \cong 3V_{cb}(1 + \frac{1}{2}[(M_R^{-1})_{23}/(M_R^{-1})_{33}]N\tan\theta) \).

It should be noted, finally, that in this version of the model, \( \theta \) comes out to be of order 1, so that there is no unexplained alignment in family space, and \( \epsilon \) comes out of order \( \frac{1}{10} \). (This can be seen from the relation \( m_0^0/m_0^c \cong \frac{N}{5}\epsilon\sin^2\theta \) and the relation just given for \( V_{cb}^0 \).)

In conclusion, we have shown that the group theory of \( SO(10) \) can elegantly explain the pattern of fermion masses and mixing angles without family symmetry. We find it remarkable that the nine features listed in the introduction can arise as a consequence of the simple Yukawa terms of eq.(1). We also find it remarkable that the single group-theoretical assumption \( Q \sim I_{3R} \) explains three of those relations as well as the smallness of \( m_0^0/m_0^c \). The fact that the gauge group is \( SO(10) \) has played several crucial roles in the model: it relates the up quarks and neutrinos to the down quarks and leptons, it allows the VEVs of the adjoint Higgs fields to point in the \( I_{3R} \) and \( X \) directions, and it makes possible the antisymmetric contributions to the mass matrices coming from \( W_{\text{vector}} \). We have only discussed terms in the superpotential that are directly relevant to understanding the pattern of light fermion masses. Other terms will be present including the Higgs sector\(^{12} \) and additional small Yukawa couplings\(^{18} \), but our results are not sensitive to these. Details of the numerical fits and certain technical points will be presented in a longer paper.

14. All parameters (e.g. \( \epsilon, c_i, c'_i, e_i, e'_i \)) are assumed to be complex. With their phases of order unity sufficient KM CP violation results.

15. \( \tan \beta \approx v/v' \) holds only if the mixing of \( \mathbf{5}(16_H) \) with the \( \mathbf{5}(10_H) \) is small. The smallness of this mixing can naturally explain why the \( c_{ij} \ll 1 \). For a discussion of gauge hierarchy including such mixing, see Ref. (16).
