Stochastic control for a class of nonlinear kernels and applications

Dylan POSSAMAI † Xiaolu TAN‡ Chao ZHOU§

October 29, 2015

Abstract

We consider a stochastic control problem for a class of nonlinear kernels. More precisely, our problem of interest consists in the optimization, over a set of possibly non-dominated probability measures, of solutions of backward stochastic differential equations (BSDEs). Since BSDEs are non-linear generalizations of the traditional (linear) expectations, this problem can be understood as stochastic control of a family of nonlinear expectations, or equivalently of nonlinear kernels. Our first main contribution is to prove a dynamic programming principle for this control problem in an abstract setting, which we then use to provide a semimartingale characterization of the value function. We next explore several applications of our results. We first obtain a wellposedness result for second order BSDEs (as introduced in [76]) which does not require any regularity assumption on the terminal condition and the generator. Then we prove a non-linear optional decomposition in a robust setting, extending recent results of [63], which we then use to obtain a superhedging duality in uncertain, incomplete and non-linear financial markets. Finally, we relate, under additional regularity assumptions, the value function to a viscosity solution of an appropriate path-dependent partial differential equation (PPDE).

Key words: Stochastic control, measurable selection, non-linear kernels, second order BSDEs, path-dependent PDEs, robust superhedging

AMS 2000 subject classifications:

1 Introduction

The dynamic programming principle (DPP for short) has been a major tool in the control theory, since the latter took off in the 1970’s. Informally speaking, this principle simply states
that a global optimization problem can be split into a series of local optimization problems. Although such a principle is extremely intuitive, its rigorous justification has proved to be a surprisingly difficult issue. Hence, for stochastic control problems, the dynamic programming principle is generally based on the stability of the controls with respect to conditioning and concatenation, together with a measurable selection argument, which, roughly speaking, allow to prove the measurability of the associated value function, as well as constructing almost optimal controls through "pasting". This is exactly the approach followed by Bertsekas and Shreve [5], and Dellacherie [23] for discrete time stochastic control problems. In continuous time, a comprehensive study of the dynamic programming principle remained more elusive. Thus, El Karoui, in [31], established the dynamic programming principle for the optimal stopping problem in a continuous time setting, using crucially the strong stability properties of stopping times, as well as the fact that the measurable selection argument can be avoided in this context, since an essential supremum over stopping times can be approximated by a supremum over a countable family of random variables. Later, for general controlled Markov processes (in continuous time) problems, El Karoui [31], and El Karoui, Huu Nguyen and Jeanblanc [33] provided a framework to derive the dynamic programming principle using the measurable selection theorem, by interpreting the controls as probability measures on the canonical trajectory space (see e.g. Theorems 6.2, 6.3 and 6.4 of [33]). Another commonly used approach to derive the DPP was to bypass the measurable selection argument by proving, under additional assumptions, a priori regularity of the value function. This was the strategy adopted, among others, by Fleming and Soner [39], and in the so-called weak DPP of Bouchard and Touzi [13], which has then been extended by Bouchard and Nutz [8, 9] and Bouchard, Moreau and Nutz [7] to optimal control problems with state constraints as well as to differential games (see also Dumitrescu, Quenez and Sulem [28] for a combined stopping/control problem on BSDEs). One of the main motivations of this weak DPP is that it is generally enough to characterize the value function as a viscosity solution of the associated Hamilton-Jacobi-Bellman partial differential equation (PDE). Let us also mention the so-called stochastic Perron’s method, which has been developed by Bayraktar and Sirbu, see e.g. [4], which allows, for Markov problems, to obtain the viscosity solution characterization of the value function without using the DPP, and then to prove the latter a posteriori. Recently, motivated by the emerging theory of robust finance, Nutz et al. [59, 65] gave a framework which allowed to prove the dynamic programming principle for sub-linear expectations (or equivalently a non-Markovian stochastic control problem), where the essential arguments are close to those in [33], though the presentation is more modern, pedagogic and accessible. The problem in continuous-time has also been studied by El Karoui and Tan [37, 38], in a more general context than the previous references, but still based on the same arguments as in [33] and [59].

However, all the above works consider only what needs to be qualified as the sub-linear case. Indeed, the control problems considered consists generically in the maximization of a family of expectations over the set of controls. Nonetheless, so-called non-linear expectations on a given probability space (that is to say operators acting on random variables which preserve all the properties of expectations but linearity) have now a long history, be it from the capacity theory, used in economics to axiomatize preferences of economic agents which do not satisfy the usual axiom’s of von Neumann and Morgenstern, or from the so-called \( g \)-expectations (or BSDEs) introduced by Peng [68]. Before pursuing, let us just recall that in the simple setting
of a probability space carrying a Brownian motion $W$, with its (completed) natural filtration $\mathcal{F}$, finding the solution of a BSDE with generator $g$ and terminal condition $\xi \in \mathcal{F}_T$ amounts to finding a pair of $\mathcal{F}$–progressively measurable processes $(Y, Z)$ such that

$$Y_t = \xi - \int_t^T g_s(Y_s, Z_s)\,ds - \int_t^T Z_s \cdot dW_s, \quad t \in [0, T], \text{ a.s.}$$

This theory is particularly attractive from the point of view of stochastic control, since it is constructed to be filtration (or time) consistent, that is to say that its conditional version satisfies a tower property similar to that of linear expectations, which is itself a kind of dynamic programming principle. Furthermore, it has been proved by Coquet et al. [17] that essentially all filtration consistent non-linear expectations satisfying appropriate domination properties could be represented with BSDEs (we refer the reader to [43] and [16] for more recent extensions of this result). Our first contribution in this paper, in Section 2, is therefore to generalize the measurable selection argument to derive the dynamic programming principle in the context of optimal stochastic control of nonlinear expectations (or kernels) which can be represented by BSDEs (which as mentioned above is not such a stringent assumption). We emphasize that such an extension is certainly not straightforward. Indeed, in the context of linear expectations, there is a very well established theory studying how the measurability properties of a given map are impacted by its integration with respect to a so-called stochastic kernel (roughly speaking one can see this as a regular version of a conditional expectation in our context, see for instance [5, Chapter 7]). For instance, integrating a Borel map with respect to a Borel stochastic kernel preserves the Borel measurability. However, in the context of BSDEs, one has to integrate with respect to non-linear stochastic kernels, for which, as far as we know, no such theory of measurability exists. Moreover, we also obtain a semi-martingale decomposition for the value function of our control problem. This is the object of Section 3.

Let us now explain where our motivation for studying this problem stems from. The problem of studying a controlled system of BSDEs is not new. For instance, it was shown by El Karoui and Quenez [35] (see also [36] and the references therein) that a stochastic control problem with control on the drift only could be represented via a controlled family of BSDEs (which can actually be itself represented by a unique BSDE with convex generator). More recently, motivated by obtaining probabilistic representations for fully non-linear PDEs, Soner, Touzi and Zhang [76, 78] (see also the earlier works [15] and [77]) introduced a notion of second-order BSDEs (2BSDEs for short), whose solutions could actually be written as a supremum, over a family of non-dominated probability measures (unlike in [35] where the family is dominated), of standard BSDEs. Therefore the 2BSDEs fall precisely in the class of problem that we want to study, that is stochastic control of nonlinear kernels. The authors of [76, 78] managed to obtain the dynamic programming principle, but under very strong continuity assumptions w.r.t. $\omega$ on the terminal condition and the generator of the BSDEs, and obtained a semi-martingale decomposition of the value function of the corresponding stochastic control problem, which ensured wellposedness of the associated 2BSDE. Again, these regularity assumptions are made to obtain the continuity of the value function a priori, which allows to avoid completely the use of the measurable selection theorem. Since then, the 2BSDE theory has been extended by allowing more general generators, filtrations and constraints (see [71, 72, 57, 56, 48, 49]), but no progress has been made concerning the regularity assumptions. However, the 2BSDEs (see for instance [58]) have proved to provide a particularly nice framework to study the so-called
robust problems in finance, which were introduced by [2, 54] and in a more rigorous setting by [25]. However, the regularity assumptions put strong limitations to the range of the potential applications of the theory.

We also would like to mention a related theory developed around the notion of $G$–expectations introduced by Peng [70], which lead to the so-called $G$–BSDEs (see [44, 45]). Instead of working on a fixed probability space carrying different probability measures corresponding to the controls, they work directly on a so-called sublinear expectation space in which the canonical process already incorporates the different measures, without having to refer to a probabilistic setting. Although their method of proof is different, since they mainly use PDE arguments to construct a solution in the Markovian case and then a closure argument, the final objects are extremely close to 2BSDEs, with similar restrictions in terms of regularity. Moreover, the PDE approach they use is unlikely to be compatible with a theory without any regularity, since the PDEs they consider need at the very least to have a continuous solution. On the other hand, there is more hope for the probabilistic approach of the 2BSDEs, since, as shown in [65] in the case of linear expectations (that is when the generator of the BSDEs is 0), everything can be well defined by assuming only that the terminal condition is (Borel) measurable.

There is a third theory which shares deep links with 2BSDEs, namely that of viscosity solutions of fully non-linear path dependent PDEs (PPDEs for short), which has been introduced recently by Ekren, Touzi and Zhang [29, 30]. Indeed, they showed that the solution of a 2BSDE, with a generator and a terminal condition uniformly continuous (in $\omega$), was nothing else than the viscosity solution of a particular PPDE, making the previous theory of 2BSDEs a special case of the theory of PPDEs. The second contribution of our paper is therefore that we show (a suitable version of) the value function for which we have obtained the dynamic programming principle provides a solution to a 2BSDE without requiring any regularity assumption, a case which cannot be covered by the PPDE theory. This takes care of the existence problem, while we tackle, as usual, the uniqueness problem through $a$ priori $L^p$ estimates on the solution, for any $p > 1$. We emphasize that in the very general setting that we consider, the classical method of proof fails (in particular since the filtration we work with is not quasi-left continuous in general), and the estimates follow from a general result that we prove in our accompanying paper [12]. In particular, our wellposedness results contains as a special case the theory of BSDEs, which was not the case neither for the 2BSDEs of [76], nor the $G$–BSDE. Moreover, the class of probability measures that we can consider is much more general than the ones considered in the previous literature, even allowing for degeneracy of the diffusion coefficient. This is the object of Section 4.

The rest of the paper is mainly concerned with applications of the previous theory. First, in Section 5, we use our previous results to obtain a non-linear and robust generalization of the so-called optional decomposition for supermartingales (see for instance [35, 51] and the other references given in Section 5 for more details), which is new in the literature. This allows us to give, under an additional assumption stating that the family of measures is roughly speaking rich enough, a new definition of so-called saturated 2BSDEs. This new formulation has the advantage that it allows us to get rid of the orthogonal martingales which generically appear in the definition of a 2BSDE (see Definitions 4.1 and 5.2 for more details). This is particularly important in some applications, see for instance the general Principal-Agent problem studied in
[20]. We then give a duality result for the robust pricing of contingent claims in non-linear and incomplete financial markets. Finally, in Section 6, we recall in our context the link between 2BSDEs and PPDEs when we work under additional regularity assumptions. Compared to [29], our result can accommodate degenerate diffusions.

To conclude this introduction, we really want to insist on the fact that our new results have much more far-reaching applications, and are not a mere mathematical extension. Indeed, in the paper [20], the wellposedness theory of 2BSDEs we have obtained is used crucially to solve general Principal-Agent problems in contracting theory, when the agent controls both the drift and the volatility of the corresponding output process (we refer the reader to the excellent monograph [21] for more details on contracting theory), a problem which could not be treated with the techniques prevailing in the previous literature. Such a result has potential applications in many fields, ranging from economics (see for instance [19, 55]) to energy management (see [1]).

**Notations:** Throughout this paper, we fix a constant \( p > 1 \). Let \( \mathbb{N}^* := \mathbb{N} \setminus \{0\} \) and let \( \mathbb{R}^*_+ \) be the set of real positive numbers. For every \( d \)-dimensional vector \( b \) with \( d \in \mathbb{N}^* \), we denote by \( b^1, \ldots, b^d \) its coordinates and for \( \alpha, \beta \in \mathbb{R}^d \) we denote by \( \alpha \cdot \beta \) the usual inner product, with associated norm \( \| \cdot \| \), which we simplify to \( | \cdot | \) when \( d \) is equal to \( 1 \). We also let \( 1_d \) be the vector whose coordinates are all equal to \( 1 \). For any \( (l, c) \in \mathbb{N}^* \times \mathbb{N}^* \), \( \mathcal{M}_{l,c}(\mathbb{R}) \) will denote the space of \( l \times c \) matrices with real entries. Elements of the matrix \( M \in \mathcal{M}_{l,c} \) will be denoted by \( (M_{ij})_{1 \leq i \leq l, 1 \leq j \leq c} \) and the transpose of \( M \) will be denoted by \( M^\top \). When \( l = c \), we let \( \mathcal{M}_l(\mathbb{R}) := \mathcal{M}_{l,l}(\mathbb{R}) \). We also identify \( \mathcal{M}_l(\mathbb{R}) \) and \( \mathbb{R}^l \). Let \( \mathbb{S}^\geq_{d} \) denote the set of all symmetric positive semi-definite \( d \times d \) matrices. We fix a map \( \psi : \mathbb{S}^\geq_{d} \to \mathcal{M}_d(\mathbb{R}) \) which is (Borel) measurable and satisfies \( \psi(a)(\psi(a))^\top = a \) for all \( a \in \mathbb{S}^\geq_{d} \), and denote \( a^\frac{1}{2} := \psi(a) \).

## 2 Stochastic control for a class of nonlinear stochastic kernels

### 2.1 Probabilistic framework

#### 2.1.1 Canonical space

Let \( d \in \mathbb{N}^* \), we denote by \( \Omega := C([0,T], \mathbb{R}^d) \) the canonical space of all \( \mathbb{R}^d \)-valued continuous paths \( \omega \) on \([0,T] \) such that \( \omega_0 = 0 \), equipped with the canonical process \( X \), i.e. \( X_t(\omega) := \omega_t \), for all \( \omega \in \Omega \). Denote by \( \mathcal{F} = (\mathcal{F}_t)_{0 \leq t \leq T} \) the canonical filtration generated by \( X \), and by \( \mathcal{F}_+ = (\mathcal{F}^+_t)_{0 \leq t \leq T} \) the right limit of \( \mathcal{F} \) with \( \mathcal{F}^+_t := \bigcap_{s > t} \mathcal{F}_s \) for all \( t \in [0,T) \) and \( \mathcal{F}_T^+ := \mathcal{F}_T \). We equip \( \Omega \) with the uniform convergence norm \( \| \omega \|_\infty := \sup_{0 \leq t \leq T} |\omega_t| \), so that the Borel \( \sigma \)-field of \( \Omega \) coincides with \( \mathcal{F}_T \). Let \( \mathbb{P}_0 \) denote the Wiener measure on \( \Omega \) under which \( X \) is a Brownian motion.

Let \( \mathbb{M}_1 \) denote the collection of all probability measures on \((\Omega, \mathcal{F}_T)\). Notice that \( \mathbb{M}_1 \) is a Polish space equipped with the weak convergence topology. We denote by \( \mathcal{B} \) its Borel \( \sigma \)-field. Then for any \( \mathbb{P} \in \mathbb{M}_1 \), denote by \( \mathcal{F}^\mathbb{P}_T \) the completed \( \sigma \)-field of \( \mathcal{F}_T \) under \( \mathbb{P} \). Denote also the completed filtration by \( \mathbb{P}^\mathbb{F}_+ = (\mathcal{F}^\mathbb{F}_t)_{t \in [0,T]} \) and \( \mathbb{P}^\mathbb{P}_+ \) the right limit of \( \mathbb{P}^\mathbb{F} \), so that \( \mathbb{P}^\mathbb{P}_+ \) satisfies the usual conditions. Moreover, for \( \mathbb{P} \subset \mathbb{M}_1 \), we introduce the universally completed filtration
\( \bar{\Omega} := \Omega \times \Omega' \), where \( \Omega' \) is identical to \( \Omega \). By abuse of notation, we denote by \( (X, B) \) its canonical process, i.e. \( X_t(\bar{\omega}) := \omega_t, B_t(\bar{\omega}) := \omega'_t \) for all \( \bar{\omega} := (\omega, \omega') \in \bar{\Omega} \), by \( \bar{\mathbb{F}} = (\mathcal{F}_t)_{0 \leq t \leq T} \) the canonical filtration generated by \( (X, B) \), and by \( \bar{\mathbb{F}}^X = (\mathcal{F}_t^X)_{0 \leq t \leq T} \) the filtration generated by \( X \). Similarly, we denote the corresponding right-continuous filtrations by \( \bar{\mathbb{P}}_+ \) and \( \bar{\mathbb{F}}_+ \), and the augmented filtration by \( \bar{\mathbb{P}}_+ \bar{\mathbb{F}} \) and \( \bar{\mathbb{F}}_+ \), given a probability measure \( \bar{\mathbb{P}} \) on \( \bar{\Omega} \).

### 2.1.2 Semi-martingale measures

We say that a probability measure \( \mathbb{P} \) on \( (\Omega, \mathcal{F}_T) \) is a semi-martingale measure if \( X \) is a semi-martingale under \( \mathbb{P} \). Then on the canonical space \( \Omega \), there is some \( \mathbb{F} \)—progressively measurable non-decreasing process (see e.g. Karandikar [47]), denoted by \( (\lambda) = ((\lambda)_{t})_{0 \leq t \leq T} \), which coincides with the quadratic variation of \( X \) under each semi-martingale measure \( \mathbb{P} \). Define further

\[
\hat{a}_t := \limsup_{\varepsilon \downarrow 0} \frac{\langle X \rangle_t - \langle X \rangle_{t-\varepsilon}}{\varepsilon}.
\]

For every \( t \in [0, T] \), let \( \mathcal{P}_t^\mathbb{W} \) denote the collection of all probability measures \( \mathbb{P} \) on \( (\Omega, \mathcal{F}_T) \) such that

- \((X_s)_{s \in [t, T]}\) is a \((\mathbb{P}, \mathbb{F})\)—semi-martingale admitting the canonical decomposition (see e.g. [46, Theorem I.4.18])

\[
X_s = \int_t^s b_r^\mathbb{F} \, dr + X^c_s, \quad s \in [t, T], \quad \mathbb{P} - a.s.,
\]

where \( b^\mathbb{F} \) is a \( \mathbb{F}^\mathbb{P} \)—predictable \( \mathbb{R}^d \)—valued process, and \( X^c \) is the continuous local martingale part of \( X \) under \( \mathbb{P} \).

- \(((\lambda)_s)_{s \in [t, T]}\) is absolutely continuous in \( s \) with respect to the Lebesgue measure, and \( \hat{a} \)

\[
\lambda(\bar{\omega}) := \lambda(\omega), \quad \forall \bar{\omega} = (\omega, \omega') \in \bar{\Omega}.
\]

Given a random variable or process \( \lambda \) defined on \( \Omega \), we can naturally define its extension on \( \bar{\Omega} \) (which, abusing notations slightly, we still denote by \( \lambda \)) by

\[
\lambda(\bar{\omega}) := \lambda(\omega), \quad \forall \bar{\omega} = (\omega, \omega') \in \bar{\Omega}.
\]

In particular, the process \( \hat{a} \) can be extended on \( \bar{\Omega} \). Given a probability measure \( \mathbb{P} \in \mathcal{P}_t^\mathbb{W} \), we define a probability measure \( \bar{\mathbb{P}} \) on the enlarged canonical space \( \bar{\Omega} \) by \( \bar{\mathbb{P}} := \mathbb{P} \otimes \mathbb{P}_0 \), so that \( X \) in \( (\bar{\Omega}, \mathcal{F}_T, \bar{\mathbb{P}}, \bar{\mathbb{F}}) \) is a semi-martingale with the same triplet of characteristics as \( X \) in \( (\Omega, \mathcal{F}_T, \mathbb{P}, \mathbb{F}) \), \( B \) is a \( \mathbb{F} \)—Brownian motion, and \( X \) is independent of \( B \). Then for every \( \mathbb{P} \in \mathcal{P}_t^\mathbb{W} \), there is some \( \mathbb{R}^d \)—valued, \( \mathbb{F} \)—Brownian motion \( W^\mathbb{P} = (W^\mathbb{P}_r)_{0 \leq r \leq s} \) such that (see e.g. Theorem 4.5.2 of [80])

\[
X_s = \int_t^s b_r^\mathbb{F} \, dr + \int_t^s \frac{1}{\hat{a}^2} dW^\mathbb{P}_r, \quad s \in [t, T], \quad \bar{\mathbb{P}} - a.s.,
\]

\[
\text{for all}
\]
where we extend the definition of $\hat{b}^P$ and $\hat{a}$ on $\Omega$ as in (2.1), and where we recall that $\hat{a}^{1/2}$ has been defined in the Notations above.

Notice that when $\hat{a}_r$ is non-degenerate $P - a.s.$, for all $r \in [t, T]$, then we can construct the Brownian motion $W^P$ on $\Omega$ by

$$W^P_t := \int_0^t \hat{a}_s^{-1/2} dX^{c, P}_s, \ t \in [0, T], \ P - a.s.,$$

and do not need to consider the above enlarged space equipped with an independent Brownian motion to construct $W^P$.

**Remark 2.1** (On the choice of $\hat{a}^{1/2}$). The measurable map $a \mapsto \hat{a}^{1/2}$ is fixed throughout the paper. A first choice is to take $a^{1/2}$ as the unique non-negative symmetric square root of $a$ (see e.g. Lemma 5.2.1 of [80]). One can also use the Cholesky decomposition to obtain $a^{1/2}$ as a lower triangular matrix. Finally, when $d = m + n$ for $m, n \in \mathbb{N}^*$, and $\hat{a}$ has the specific structure of Remark 2.2 below, one can take $\hat{a}^{1/2}$ in the following way:

$$a = \begin{pmatrix} \sigma \sigma^T \\ \sigma^T \ I_n \end{pmatrix} \quad \text{and} \quad a^{1/2} = \begin{pmatrix} \sigma & 0 \\ I_n & 0 \end{pmatrix}, \quad \text{for some } \sigma \in \mathcal{M}_{m,n}.$$ (2.3)

### 2.1.3 Conditioning and concatenation of probability measures

We also recall that for every probability measure $P$ on $\Omega$ and $\mathcal{F}$-stopping time $\tau$ taking value in $[0, T]$, there exists a family of regular conditional probability distribution (r.c.p.d. for short) $(P^\tau_\omega)_{\omega \in \Omega}$ (see e.g. Stroock and Varadhan [80]), satisfying:

(i) For every $\omega \in \Omega$, $P^\tau_\omega$ is a probability measure on $(\Omega, \mathcal{F})$.

(ii) For every $E \in \mathcal{F}$, the mapping $\omega \mapsto P^\tau_\omega(E)$ is $\mathcal{F}$-measurable.

(iii) The family $(P^\tau_\omega)_{\omega \in \Omega}$ is a version of the conditional probability measure of $P$ on $\mathcal{F}_\tau$, i.e., for every integrable $\mathcal{F}_\tau$-measurable random variable $\xi$ we have $E^P[\xi | \mathcal{F}_\tau](\omega) = E^{P^\tau_\omega}[\xi]$, for $P - a.e. \omega \in \Omega$.

(iv) For every $\omega \in \Omega$, $P^\tau_\omega(\Omega^{\tau}_\omega) = 1$, where $\Omega^{\tau}_\omega := \{ \overline{\omega} \in \Omega : \overline{\omega}(s) = \omega(s), \ 0 \leq s \leq \tau(\omega) \}$.

Furthermore, given some $P$ and a family $(Q_\omega)_{\omega \in \Omega}$ such that $\omega \mapsto Q_\omega$ is $\mathcal{F}_\tau$-measurable and $Q_\omega(\Omega^{\tau}_\omega) = 1$ for all $\omega \in \Omega$, one can then define a concatenated probability measure $P \otimes_{\tau} Q$ by

$$P \otimes_{\tau} Q[A] := \int_{\Omega} Q_\omega[A] \, P(d\omega), \ \forall A \in \mathcal{F}_\tau.$$

### 2.1.4 Hypotheses

We shall consider a random variable $\xi : \Omega \rightarrow \mathbb{R}$ and a generator function

$$f : (t, \omega, y, z, a, b) \in [0, T] \times \Omega \times \mathbb{R} \times \mathbb{R}^d \times \mathbb{S}_{d}^{\geq 0} \times \mathbb{R}^d \rightarrow \mathbb{R}.$$
Define for simplicity
\[ \tilde{f}_s^p(y, z) := f(s, X_{\Lambda_s}, y, z, \tilde{a}_s, b_s^p) \quad \text{and} \quad \tilde{f}_s^{p,0} := f(s, X_{\Lambda_s}, 0, 0, \tilde{a}_s, b_s^p). \]

Moreover, we are given a family \((P_t(\omega))_{t, \omega \in [0, T] \times \Omega}\) of sets of probability measures on \((\Omega, \mathcal{F}_t)\), where \(P(t, \omega) \subset P_t^{W} \) for all \((t, \omega) \in [0, T] \times \Omega\). Denote also \(P_t := \cup_{\omega \in \Omega} P(t, \omega)\). We make the following assumption on \(\xi, f\) and the family \((P(t, \omega))_{t, \omega \in [0, T] \times \Omega}\).

**Assumption 2.1.**

(i) The random variable \(\xi\) is \(\mathcal{F}_t\)-measurable, the generator function \(f\) is jointly Borel measurable and such that for every \((t, \omega, y, y', z, z', a, b) \in [0, T] \times \Omega \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^d \times \mathbb{R}^d \times S^2_{d} \times \mathbb{R}^d\),
\[ |f(t, \omega, y, z, a, b) - f(t, \omega, y', z', a, b)| \leq C \left( |y - y'| + ||z - z'|| \right), \]
and for every fixed \((y, z, a, b)\), the map \((t, \omega) \mapsto f(t, \omega, y, z, a, b)\) is \(\mathbb{F}\)-progressively measurable.

(ii) For the fixed constant \(p > 1\), one has for every \((t, \omega) \in [0, T] \times \Omega\),
\[ \sup_{P \in P(t, \omega)} \mathbb{E}^P \left[ |\xi|^p + \int_t^T |f(s, X_{\Lambda_s}, 0, 0, \tilde{a}_s, b_s^p)|^p ds \right] < +\infty. \quad (2.4) \]

(iii) For every \((t, \omega) \in [0, T] \times \Omega\), one has \(P(t, \omega) = P(t, \omega_{\Lambda_t})\) and \(P(\Omega_{\omega}^+) = 1\) whenever \(P \in P(t, \omega)\). The graph \([[P]]\) of \(P\), defined by \([[P]] := \{(t, \omega, P) : P \in P(t, \omega)\}\), is upper semi-analytic in \([0, T] \times \Omega \times \mathcal{M}_1\).

(iv) \(P\) is stable under conditioning, i.e. for every \((t, \omega) \in [0, T] \times \Omega\) and every \(P \in P(t, \omega)\) together with an \(\mathbb{F}\)-stopping time \(\tau\) taking values in \([t, T]\), there is a family of r.c.p.d. \((P_w)_{w \in \Omega}\) such that \(P_w \in P(\tau(\omega), \omega)\), for \(P\) - a.e. \(w \in \Omega\).

(v) \(P\) is stable under concatenation, i.e. for every \((t, \omega) \in [0, T] \times \Omega\) and \(P \in P(t, \omega)\) together with an \(\mathbb{F}\)-stopping time \(\tau\) taking values in \([t, T]\), let \((Q_w)_{w \in \Omega}\) be a family of probability measures such that \(Q_w \in P(\tau(w), \omega)\) for all \(w \in \Omega\) and \(w \mapsto Q_w\) is \(\mathcal{F}_\tau\)-measurable, then the concatenated probability measure \(P \otimes_{\tau} Q \in P(t, \omega)\).

We notice that for \(t = 0\), we have \(P_0 := P(0, \omega)\) for any \(\omega \in \Omega\).

### 2.2 Spaces and norms

We now give the spaces and norms which will be needed in the rest of the paper. Fix some \(t \in [0, T]\) and some \(\omega \in \Omega\). In what follows, \(\mathcal{X} := (\mathcal{X}_s)_{t \leq s \leq T}\) will denote an arbitrary filtration on \((\Omega, \mathcal{F}_t)\), and \(P\) an arbitrary element in \(P(t, \omega)\). Denote also by \(X_P\) the \(P\)-augmented filtration associated to \(X\).

For \(p \geq 1\), \(L^p_{t, \omega}(\mathcal{X})\) (resp. \(L^p_{t, \omega}(\mathcal{X}, P)\)) denotes the space of all \(\mathcal{X}_T\)-measurable scalar random variable \(\xi\) with
\[ \|\xi\|_{L^p_{t, \omega}(\mathcal{X})}^p := \sup_{P \in P(t, \omega)} \mathbb{E}^P [\|\xi\|^p] < +\infty, \quad \text{resp.} \quad \|\xi\|_{L^p_{t, \omega}(P)}^p := \mathbb{E}^P [\|\xi\|^p] < +\infty \]
$\mathbb{H}^p_{t,\omega}(X)$ (resp. $\mathbb{H}^p_{t,\omega}(X, P)$) denotes the space of all $X$–predictable $\mathbb{R}^d$–valued processes $Z$, which are defined $\tilde{\alpha}_s ds$–$a.e.$ on $[t, T]$, with

$$
\|Z\|_{\mathbb{H}^p_{t,\omega}}^p := \sup_{P \in \mathcal{P}(t, \omega)} \mathbb{E}^P \left[ \left( \int_t^T \|\tilde{\alpha}_s^{1/2} Z_s\|^2 ds \right)^{\frac{p}{2}} \right] < +\infty,
$$

(resp. $\|Z\|_{\mathbb{H}^p_{t,\omega}(P)}^p := \mathbb{E}^P \left[ \left( \int_t^T \|\tilde{\alpha}_s^{1/2} Z_s\|^2 ds \right)^{\frac{p}{2}} \right] < +\infty$).

$M^p_{t,\omega}(X, P)$ denotes the space of all $(X, P)$–optional martingales $M$ with $P$–$a.s.$ càdlàg paths on $[t, T]$, with $M_t = 0$, $P$–$a.s.$, and

$$
\|M\|_{M^p_{t,\omega}(P)}^p := \mathbb{E}^P \left[ |M_T|^p \right] < +\infty.
$$

Furthermore, we will say that a family $(M^p_P)_{P \in \mathcal{P}(t, \omega)}$ belongs to $M^p_{t,\omega}((X, P)_{P \in \mathcal{P}(t, \omega)})$ if, for any $P \in \mathcal{P}(t, \omega)$, $M^p \in M^p_{t,\omega}(X, P)$ and

$$
\sup_{P \in \mathcal{P}(t, \omega)} \|M^p\|_{M^p_{t,\omega}} < +\infty.
$$

$\mathbb{I}^p_{t,\omega}(X, P)$ (resp. $\mathbb{I}^p_{t,\omega}(X, P)$) denotes the space of all $X$–predictable (resp. $X$–optional) processes $K$ with $P$–$a.s.$ càdlàg and non-decreasing paths on $[t, T]$, with $K_t = 0$, $P$–$a.s.$, and

$$
\|K\|_{\mathbb{I}^p_{t,\omega}(P)}^p := \mathbb{E}^P \left[ |K_T|^p \right] < +\infty \quad \text{(resp. } \|K\|_{\mathbb{I}^p_{t,\omega}(P)}^p := \mathbb{E}^P \left[ |K_T|^p \right] < +\infty)\).
$$

We will say that a family $(K^p_P)_{P \in \mathcal{P}(t, \omega)}$ belongs to $\mathbb{I}^p_{t,\omega}((X, P)_{P \in \mathcal{P}(t, \omega)})$ (resp. $\mathbb{I}^p_{t,\omega}((X, P)_{P \in \mathcal{P}(t, \omega)})$) if, for any $P \in \mathcal{P}(t, \omega)$, $K^p \in \mathbb{I}^p_{t,\omega}(X, P)$ (resp. $K^p \in \mathbb{I}^p_{t,\omega}(X, P)$) and

$$
\sup_{P \in \mathcal{P}(t, \omega)} \|K^p\|_{\mathbb{I}^p_{t,\omega}} < +\infty \quad \text{(resp. } \sup_{P \in \mathcal{P}(t, \omega)} \|K^p\|_{\mathbb{I}^p_{t,\omega}} < +\infty)\).
$$

$\mathbb{D}^p_{t,\omega}(X)$ (resp. $\mathbb{D}^p_{t,\omega}(X, P)$) denotes the space of all $X$–progressively measurable $\mathbb{R}$–valued processes $Y$ with $P(t, \omega)$ –$q.s.$ (resp. $P$–$a.s.$) càdlàg paths on $[t, T]$, with

$$
\|Y\|_{\mathbb{D}^p_{t,\omega}}^p := \sup_{P \in \mathcal{P}(t, \omega)} \mathbb{E}^P \left[ \sup_{t \leq s \leq T} |Y_s|^p \right] < +\infty, \quad \text{(resp. } \|Y\|_{\mathbb{D}^p_{t,\omega}(P)}^p := \mathbb{E}^P \left[ \sup_{t \leq s \leq T} |Y_s|^p \right] < +\infty)\).
$$

For each $\xi \in \mathbb{L}^1_{t,\omega}(X)$ and $s \in [t, T]$ denote

$$
\mathbb{E}^{\mathbb{P}, t, \omega, X}[\xi] := \esssup_{P' \in \mathcal{P}(t, \omega, X)} \mathbb{E}^{P'}[\xi | \mathcal{F}_s] \text{ where } \mathcal{P}(t, \omega, X) := \left\{ P' \in \mathcal{P}(t, \omega), \ P' = \mathbb{P} \text{ on } \mathcal{X}_s \right\}.
$$

Then we define for each $p \geq 1$, $\kappa \geq 1$,

$$
\mathbb{L}^{p, \kappa}_{t,\omega}(X) := \left\{ \xi \in \mathbb{L}^1_{t,\omega}(X), \ \|\xi\|_{\mathbb{L}^{p, \kappa}_{t,\omega}} < +\infty \right\},
$$

where

$$
\|\xi\|_{\mathbb{L}^{p, \kappa}_{t,\omega}} := \sup_{P \in \mathcal{P}(t, \omega)} \mathbb{E}^P \left[ \esssup_{t \leq s \leq T} \left( \mathbb{E}^{\mathbb{P}, t, \omega, \mathbb{P}^+}[|\xi|^\kappa] \right)^{\frac{p}{\kappa}} \right]^{\frac{1}{p}}.
$$

Similarly, given a probability measure $\mathbb{P}$ and a filtration $\mathcal{F}$ on the enlarged canonical space $\Omega$, we denote the corresponding spaces by $\mathbb{D}^p_{t,\omega}(X, \mathbb{P})$, $\mathbb{H}^p_{t,\omega}(X, \mathbb{P})$, $\mathbb{M}^p_{t,\omega}(X, \mathbb{P})$, ... Furthermore, when $t = 0$, there is no longer any dependence on $\omega$, since $\omega_0 = 0$, so that we simplify the notations by suppressing the $\omega$–dependence and write $\mathbb{H}^p_0(X)$, $\mathbb{H}^p_0(X, \mathbb{P})$,... Similar notations are used on the enlarged canonical space.
2.3 Control on a class of nonlinear stochastic kernels and the dynamic programming principle

For every \((t, \omega) \in [0, T] \times \Omega\) and \(P \in \mathcal{P}(t, \omega)\), we consider the following BSDE

\[
\mathcal{Y}_s = \xi - \int_s^T f \left( r, X_{r, \omega}, \mathcal{Y}_r, \tilde{a}_{r, \omega}^{1/2} \mathcal{Z}_r, \tilde{b}_{r, \omega}^P \right) dr - \left( \int_s^T \mathcal{Z}_r \cdot dX_{r, \omega}^{c,P} \right)^P - \int_s^T d\mathcal{M}_r, \ P - a.s. \quad (2.5)
\]

Following El Karoui and Huang [32], a solution to BSDE (2.5) is a triple \((\mathcal{Y}_s^P, \mathcal{Z}_s^P, \mathcal{M}_s^P)_{s \in [t, T]} \in \mathbb{D}_t^P(\mathbb{P}_+^P) \times \mathbb{H}_t^P(\mathbb{P}_+^P, \mathbb{P}) \times \mathcal{M}_t^P(P_+^P, \mathbb{P})\) satisfying the equality (2.5) under \(P\) (wellposedness is a consequence of Lemma 2.2 below).

We then define, for every \((t, \omega) \in [0, T] \times \Omega\),

\[
\widehat{\mathcal{Y}}_t(\omega) := \sup_{P \in \mathcal{P}(t, \omega)} \mathbb{E}^P\left[ \mathcal{Y}_t^P \right]. \quad (2.6)
\]

Our first main result is the following dynamic programming principle.

**Theorem 2.1.** Suppose that Assumption 2.1 holds true. Then for all \((t, \omega) \in [0, T] \times \Omega\), one has \(\widehat{\mathcal{Y}}_t(\omega) = \widehat{\mathcal{Y}}_t(\omega_{\omega \Lambda})\), and \((t, \omega) \mapsto \widehat{\mathcal{Y}}_t(\omega)\) is \(\mathcal{B}([0, T]) \otimes \mathcal{F}_T\)–universally measurable. Moreover, for all \((t, \omega) \in [0, T] \times \Omega\) and \(\mathbb{F}\)–stopping time \(\tau\) taking values in \([t, T]\), we have

\[
\widehat{\mathcal{Y}}_t(\omega) = \sup_{P \in \mathcal{P}(t, \omega)} \mathbb{E}^P\left[ \mathcal{Y}_t^P(\tau, \widehat{Y}_\tau) \right],
\]

where \(\mathcal{Y}_t^P(\tau, \widehat{Y}_\tau)\) is obtained from the solution to the following BSDE with terminal time \(\tau\) and terminal condition \(\widehat{Y}_\tau\),

\[
\mathcal{Y}_t = \widehat{Y}_\tau - \int_t^\tau f \left( s, X_{s, \omega}, \mathcal{Y}_s, \tilde{a}_{s, \omega}^{1/2} Z_s, \tilde{b}_{s, \omega}^P \right) ds - \left( \int_t^\tau Z_s \cdot dX_{s, \omega}^{c,P} \right)^P - \int_t^\tau d\mathcal{M}_s, \ P - a.s. \quad (2.7)
\]

**Remark 2.2.** In some contexts, the sets \(\mathcal{P}(t, \omega)\) are defined as the collections of probability measures induced by a family of controlled diffusion processes. For example, let \(\mathcal{C}_1\) (resp. \(\mathcal{C}_2\)) denote the canonical space of all continuous paths \(\omega^1\) in \(\mathcal{C}([0, T], \mathbb{R}^m)\) (resp. \(\omega^2\) in \(\mathcal{C}([0, T], \mathbb{R}^n)\)) such that \(\omega_0^1 = 0\) (resp. \(\omega_0^2 = 0\)), with canonical process \(B\), canonical filtration \(\mathcal{F}^1\), and let \(P_0\) be the corresponding Wiener measure. Let \(U\) be a Polish space, \((\mu, \sigma) : [0, T] \times \mathcal{C}_1 \times U \rightarrow \mathbb{R}^n \times \mathcal{M}_{n,m}\) be the coefficient functions, then, given \((t, \omega^1) \in [0, T] \times \mathcal{C}_1\), we denote by \(\mathcal{F}(t, \omega^1)\) the collection of all terms

\[
\alpha := (\mathcal{O}^\alpha, \mathcal{F}^\alpha, \mathbb{P}^\alpha, \mathcal{P}^\alpha) = (\mathcal{F}_t^\alpha)_{t \geq 0}, \mathcal{W}^\alpha, (\nu_t^\alpha)_{t \geq 0}, X^\alpha),
\]

where \((\Omega^\alpha, \mathcal{F}^\alpha, \mathbb{P}^\alpha, \mathcal{P}^\alpha)\) is a filtered probability space, \(\mathcal{W}^\alpha\) is a \(\mathcal{F}^\alpha\)–Brownian motion, \(\nu^\alpha\) is a \(U\)–valued \(\mathcal{F}^\alpha\)–predictable process and \(X^\alpha\) solves the SDE (under some appropriate additional conditions on \(\mu\) and \(\sigma\)), with initial condition \(X_0^\alpha = \omega_0^1\) for all \(s \in [0, t]\),

\[
X_s^\alpha = \omega_t^1 + \int_t^s \mu(r, X_{r, \omega}^\alpha, \nu_r) dr + \int_t^s \sigma(r, X_{r, \omega}^\alpha, \nu_r) d\mathcal{W}_r^\alpha, \ s \in [t, T], \ P^\alpha - a.s.
\]

In this case, one can let \(d = m + n\) so that \(\Omega = \mathcal{C}_1 \times \mathcal{C}_2\) and define \(\mathcal{P}(t, \omega)\) for \(\omega = (\omega^1, \omega^2)\) as the collection of all probability measures induced by \((X^\alpha, B^\alpha)_{\alpha \in \mathcal{F}(t, \omega^1)}\). Then, with the choice of \(\tilde{a}_r^{1/2}\) as in (2.3), one can obtain the matrix \(\sigma\) from the corresponding \(\tilde{a}_r^{1/2}\), which may be useful for some applications. Moreover, notice that that \(\mathcal{P}(t, \omega)\) depends only on \((t, \omega^1)\) for \(\omega = (\omega^1, \omega^2)\), then the value \(\widehat{\mathcal{Y}}_t(\omega)\) in (2.6) depends also only on \((t, \omega^1)\).
2.4 Proof of Theorem 2.1

2.4.1 An equivalent formulation on enlarged canonical space

We would like to formulate the BSDE (2.5) on the enlarged canonical space in an equivalent way. Remember that $\Omega' := \Omega \times \Omega'$ and for a probability measure $\mathbb{P}$ on $\Omega$, we define $\mathbb{F} := \mathbb{P} \otimes \mathbb{P}_0$. Then a $\mathbb{P}$-null event on $\Omega$ becomes a $\mathbb{F}$-null event on $\Omega'$ if it is considered in the enlarged space. Let $\pi : \Omega \times \Omega' \rightarrow \Omega$ be the projection operator defined by $\pi(\omega, \omega') := \omega$, for any $(\omega, \omega') \in \Omega'$.

**Lemma 2.1.** Let $A \subseteq \Omega$ be a subset in $\Omega$. Then saying that $A$ is a $\mathbb{P}$-null set is equivalent to saying that $\{\tilde{\omega} : \pi(\tilde{\omega}) \in A\}$ is a $\mathbb{F}$ := $\mathbb{P} \otimes \mathbb{P}_0$-null set.

**Proof.** For $A \subseteq \Omega$, denote $\bar{A} := \{\tilde{\omega} : \pi(\tilde{\omega}) \in A\} = A \times \Omega'$. Then by the definition of the product measure, it is clear that

$$\mathbb{P}(A) = 0 \iff \mathbb{P} \otimes \mathbb{P}_0(\bar{A}) = 0,$$

which concludes the proof. $\square$

We now consider two BSDEs on the enlarged canonical space, w.r.t. two different filtrations. The first one is the following BSDE on $(\bar{\Omega}, \mathcal{F}_T^X, \mathbb{F})$ w.r.t. the filtration $\mathbb{F}^X$:

$$\bar{Y}_s = \xi(X_\cdot) - \int_s^T f(r, X_{\cdot \land r}, \bar{Y}_r, \bar{\alpha}_r^{1/2} \bar{Z}_r, \bar{\alpha}_r, b_r^P) \, dr - \left( \int_s^T \bar{Z}_r \cdot dX_r^P \right)^\mathbb{F} - \int_s^T d\bar{M}_r, \quad \mathbb{F} - a.s.,$$

(2.8)

where a solution is a triple $(\bar{Y}_s^P, \bar{Z}_s^P, \bar{M}_s^P)_{s \in [t, T]} \in \mathbb{D}^p_{t, \omega}(\mathbb{F}^X, \mathbb{F}) \times \mathbb{H}^p_{t, \omega}(\mathbb{F}^X, \mathbb{F}) \times \mathbb{M}^p_{t, \omega}(\mathbb{F}^X, \mathbb{F})$ satisfying (2.8). Notice that in the enlargement, the Brownian motion $B$ is independent of $X$, so that the above BSDE (2.8) is equivalent to BSDE (2.5) (see Lemma 2.2 below for a precise statement and justification).

We then introduce a second BSDE on the enlarged space $(\bar{\Omega}, \mathcal{F}_T, \mathbb{F})$, w.r.t. the filtration $\mathbb{F}$,

$$\tilde{Y}_s = \xi(X_\cdot) - \int_s^T f(r, X_{\cdot \land r}, \tilde{Y}_r, \tilde{\alpha}_r^{1/2} \tilde{Z}_r, \tilde{\alpha}_r, \tilde{b}_r^P) \, dr - \left( \int_s^T \tilde{Z}_r \cdot dW_r^P \right)^\mathbb{F} - \int_s^T d\tilde{M}_r, \quad \mathbb{F} - a.s.,$$

(2.9)

where a solution is a triple $(\tilde{Y}_s^P, \tilde{Z}_s^P, \tilde{M}_s^P)_{s \in [t, T]} \in \mathbb{D}^p_{t, \omega}(\mathbb{F}, \mathbb{F}) \times \mathbb{H}^p_{t, \omega}(\mathbb{F}, \mathbb{F}) \times \mathbb{M}^p_{t, \omega}(\mathbb{F}, \mathbb{F})$ satisfying (2.9).

**Lemma 2.2.** Let $(t, \omega) \in [0, T] \times \Omega$, $\mathbb{P} \in \mathcal{P}(t, \omega)$ and $\mathbb{F} := \mathbb{P} \otimes \mathbb{P}_0$, then each of the three BSDEs (2.5), (2.8) and (2.9) has a unique solution, denoted respectively by $(Y, Z, M)$, $(\bar{Y}, \bar{Z}, \bar{M})$ and $(\tilde{Y}, \tilde{Z}, \tilde{M})$. Moreover, their solution coincide in the sense that there is some functional

$$\Psi := (\Psi^Y, \Psi^Z, \Psi^M) : [t, T] \times \Omega \rightarrow \mathbb{R} \times \mathbb{R}^d \times \mathbb{R},$$

such that $\Psi^X$ and $\Psi^M$ are $\mathbb{F}^+ -$progressively measurable and $\mathbb{P} - a.s.$ càdlàg, $\Psi^Z$ is $\mathbb{F} -$predictable,

$$Y_s = \Psi^Y_s, \quad Z_s = \Psi^Z_s, \quad \tilde{Y}_s = \tilde{Z}_s = \Psi^Z(X_s), \quad \tilde{\alpha}_s dr - a.e. \text{ on } [t, s], \quad \mathbb{M}_s = \Psi^M_s, \text{ for all } s \in [t, T], \quad \mathbb{P} - a.s.,$$

for all $s \in [t, T]$, $\mathbb{P} - a.s.$

11
Proof. (i) The existence and uniqueness of a solution to (2.9) is a classical result, we can for example refer to Theorem 4.1 of [12]. Then it is enough to show that the three BSDEs share the same solution in the sense given in the statement. Without loss of generality, we assume in the following \(t = 0\).

(ii) We next show that (2.8) and (2.9) admit the same solution in \((\Omega, \mathcal{F}_T^\mathbb{P}, \mathbb{P})\). Notice that a solution to (2.8) is clearly a solution to (2.9) by (2.2). We then show that a solution to (2.9) is also a solution to (2.8).

Let \( \zeta : \Omega \to \mathbb{R} \) be a \( \mathcal{F}_T^\mathbb{P}\)-measurable random variable, which admits a unique martingale representation

\[
\zeta = \mathbb{E}^\mathbb{P}[\zeta] + \int_0^T \mathcal{Z}_s \cdot dX_{s}^{\mathbb{P}} + \int_0^T \mathcal{M}_s,
\]

w.r.t. the filtration \( \mathcal{F}_T^\mathbb{P}\). Since \( B \) is independent of \( X \) in the enlarged space, and since \( X \) admits the same semi-martingale triplet of characteristics in both space, the above representation (2.10) w.r.t. \( \mathcal{F}_T^\mathbb{P}\) is the same as the one w.r.t. \( \mathcal{F}_T^\mathbb{F}\), which are all unique up to a \( \mathbb{P} \)-evanescent set. Remember now that the solution of BSDE (2.9) is actually obtained as an iteration of the above martingale representation (see e.g. Section 2.4.2 below). Therefore, a solution to (2.9) is clearly a solution to (2.8).

(iii) We now show that a solution \((\mathcal{Y}_t, \mathcal{Z}_t, \mathcal{M}_t)\) to (2.8) induces a solution to (2.5). Notice that \( \mathcal{Y}_t, \mathcal{Z}_t, \mathcal{M}_t \) are \( \mathcal{F}_t^\mathbb{F}\)-optional, and \( \mathcal{Z}_t \) is \( \mathcal{F}_t^\mathbb{F}\)-predictable, then (see e.g. Lemma 2.4 of [78] and Theorem IV.78 and Remark IV.74 of [24]) there exists a functional \( (\Psi\,^Y, \Psi\,^Z, \Psi\,^M) : [0, T] \times \Omega \to \mathbb{R} \times \mathbb{R}^d \times \mathbb{R} \) such that \( \Psi\,^Y \) and \( \Psi\,^M \) are \( \mathcal{F}_T^\mathbb{F}\)-progressively measurable and \( \mathbb{P} \)-a.s. càdlàg, \( \Psi\,^Z \) is \( \mathcal{F}_T^\mathbb{F}\)-predictable, and \( \mathcal{Y}_t = \Psi\,^Y_t, \mathcal{Z}_t = \Psi\,^Z_t, \mathcal{M}_t = \Psi\,^M_t \) for all \( t \in [0, T], \mathbb{P} \)-a.s. Define

\[
(\Psi\,^{Y,0} (\omega), \Psi\,^{Z,0} (\omega), \Psi\,^{M,0} (\omega)) := (\Psi\,^Y (\omega, \mathbf{0}), \Psi\,^Z (\omega, \mathbf{0}), \Psi\,^M (\omega, \mathbf{0})),
\]

where \( \mathbf{0} \) denotes the path taking value 0 for all \( t \in [0, T] \).

Since \( (\Psi\,^Y, \Psi\,^Z, \Psi\,^M) \) are \( \mathcal{F}_T^\mathbb{F}\)-progressively measurable, the functions \( (\Psi\,^{Y,0}, \Psi\,^{Z,0}, \Psi\,^{M,0}) \) are then \( \mathcal{F}_T^\mathbb{F}\)-progressively measurable, and it is easy to see that they provide a version of a solution to (2.5) in \((\Omega, \mathcal{F}_T^\mathbb{F}, \mathbb{P})\).

(iv) Finally, let \((\mathcal{Y}_t, \mathcal{Z}_t, \mathcal{M}_t)\) be a solution to (2.5), then there exists a function \( (\Psi\,^Y, \Psi\,^Z, \Psi\,^M) : [0, T] \times \Omega \to \mathbb{R} \times \mathbb{R}^d \times \mathbb{R} \) such that \( \Psi\,^Y \) and \( \Psi\,^M \) are \( \mathcal{F}_T^\mathbb{F}\)-progressively measurable and \( \mathbb{P} \)-a.s. càdlàg, \( \Psi\,^Z \) is \( \mathcal{F}_T^\mathbb{F}\)-predictable, and \( \mathcal{Y}_t = \Psi\,^Y_t, \mathcal{Z}_t = \Psi\,^Z_t \) and \( \mathcal{M}_t = \Psi\,^M_t \) for all \( t \in [0, T], \mathbb{P} \)-a.s. Since \( \mathcal{F}_T^\mathbb{P} := \mathcal{F}_T^\mathbb{F} \otimes \mathcal{P}_0 \), it is easy to see that \( (\Psi\,^Y, \Psi\,^Z, \Psi\,^M) \) is the required functional in the lemma.

The main interest of Lemma 2.2 is that it allows us, when studying the BSDE (2.5), to equivalently work with the BSDE (2.9), in which the Brownian motion \( W^\mathbb{P}\) appears explicitly. This will be particularly important for us when using linearization arguments. Indeed, in such type of arguments, one usually introduce a new probability measure equivalent to \( \mathbb{P} \). But if we use formulation (2.5), then one must make the inverse of \( \hat{a} \) appear explicitly in the Radon-Nykodym density of the new probability measure. Since such an inverse is not always defined in our setting, we therefore take advantage of the enlarged space formulation to bypass this problem.
2.4.2 An iterative construction of the solution to BSDE (2.5)

In preparation of the proof of the dynamic programming principle for control problem in Theorem 2.1, let us first recall the classical construction of the \( Y_P \) part of the solution to the BSDE (2.5) under some probability \( P \in \mathcal{P}(t, \omega) \) using Picard’s iteration. Let us first define for any \( m \geq 0 \)

\[ \xi^m := (\xi \lor m) \land (-m), \quad f^m(t, \omega, y, z, a, b) := (f(t, \omega, y, z, a, b) \lor m) \land (-m). \]

(i) First, let \( Y_{s}^{P,0,m}(0) = 0 \) and \( Z_{s}^{P,0,m}(0) = 0 \), for all \( s \in [t, T] \).

(ii) Given a family of \( \mathbb{F}_+ \)-progressively measurable processes \( (Y_{s}^{P,n,m}, Z_{s}^{P,n,m})_{s \in [t,T]} \), we define

\[ Y_{s}^{P,n+1,m} := \mathbb{E}^P\left[ \xi - \int_{s}^{T} f(r, X_{\wedge r}, Y_{r}^{P,n,m}, Z_{r}^{P,n,m}, \tilde{a}_{r}^{1/2}, \tilde{b}_{r}^{P}) dr \bigg| \mathcal{F}_{s} \right], \quad P \text{- a.s.} \quad (2.11) \]

(iii) Let \( Y_{s}^{P,n+1,m} \) be a right-continuous modification of \( Y_{s}^{P,n+1,m} \) defined by

\[ Y_{s}^{P,n+1,m} := \limsup_{Q \ni \varepsilon \downarrow 0} Y_{s}^{P,n+1,m}, \quad P \text{- a.s.} \quad (2.12) \]

(iv) Notice that \( Y_{s}^{P,n+1,m} \) is a semi-martingale under \( P \). Let \( (Y_{s}^{P,n+1,m}, X)^P \) be the predictable quadratic covariation of the process \( Y_{s}^{P,n+1,m} \) and \( X \) under \( P \). Define

\[ \tilde{a}_{s}^{1/2} Z_{s}^{P,n+1,m} := \limsup_{Q \ni \varepsilon \downarrow 0} \frac{(Y_{s}^{P,n+1,m}, X)^P_s - (Y_{s}^{P,n+1,m}, X)^P_{s-}}{\varepsilon}. \quad (2.13) \]

(v) Notice that the sequence \( (Y_{s}^{P,n,m})_{m \geq 0} \) is a Cauchy sequence for the norm

\[ \| (Y, Z) \|_\alpha^2 := \mathbb{E}^P\left[ \int_{0}^{T} e^{\alpha s} |Y_s|^2 ds \right]^2 + \mathbb{E}^P\left[ \int_{0}^{T} e^{\alpha s} \left\| \tilde{a}_{s}^{1/2} Z_{s} \right\|^2 ds \right]^2, \]

for \( \alpha \) large enough. Indeed, this is a consequence of the classical estimates for BSDEs, for which we refer to Section 4 of [12]. Then by taking some suitable sub-sequence \( (n_k^{P,m})_{k \geq 1} \), we can define

\[ Y_{s}^{P,m} := \limsup_{k \to \infty} Y_{s}^{P,n_k^{P,m}}, \]

(vi) Finally, we can again use the estimates given in [12] (see again Section 4) to show that the sequence \( (Y_{s}^{P,m})_{m \geq 0} \) is a Cauchy sequence in \( \mathcal{D}_0^P(\mathbb{P}_+^P) \), so that by taking once more a suitable subsequence \( (m_k^{P})_{k \geq 1} \), we can define the solution to the BSDE as

\[ Y_{s}^{P} := \limsup_{k \to \infty} Y_{s}^{P,m_k^{P}}, \quad (2.14) \]

\(^1\text{Notice here that the results of [12] apply for BSDEs of the form (2.9) in the enlarged space. However, by Lemma 2.2, this implies the same convergence result in the original space.}\)
2.4.3 On the measurability issues of the iteration

Here we show that the iteration in Section 2.4.2 can be taken in a measurable way w.r.t. the reference probability measure $\mathbb{P}$, which allows us to use the measurable selection theorem to derive the dynamic programming principle.

**Lemma 2.3.** Let $\mathcal{P}$ be a measurable set in $\mathbb{M}_1$, $(\mathbb{P}, \omega, t) \mapsto H^\mathbb{P}_t(\omega)$ be a measurable function such that for all $\mathbb{P} \in \mathcal{P}$, $H^\mathbb{P}$ is right-continuous, $\mathbb{F}_+-$adapted and a $(\mathbb{P}, \mathbb{F}_+^\mathbb{P})-$semi-martingale. Then there is a measurable function $(\mathbb{P}, \omega, t) \mapsto \langle H^\mathbb{P}_t \rangle^\mathbb{P}(\omega)$ such that for all $\mathbb{P} \in \mathcal{P}$, $\langle H^\mathbb{P} \rangle^\mathbb{P}$ is right-continuous, $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$predictable, and

$$
\langle H^\mathbb{P} \rangle^\mathbb{P} \text{ is the predictable quadratic variation of the semi-martingale } H^\mathbb{P} \text{ under } \mathbb{P}.
$$

**Proof.** (i) For every $n \geq 1$, we define the following sequence of random times

$$
\begin{align*}
\tau_0^\mathbb{P}_n(\omega) &:= 0, \quad \omega \in \Omega, \\
\tau_{i+1}^\mathbb{P}_n(\omega) &:= \inf \left\{ t \geq \tau_i^\mathbb{P}_n(\omega), \left| H^\mathbb{P}_t(\omega) - H^\mathbb{P}_{\tau_i^\mathbb{P}_n}(\omega) \right| \geq 2^{-n} \right\} \wedge 1, \quad \omega \in \Omega, \ i \geq 1.
\end{align*}
$$

(2.15)

We notice that the $\tau_i^\mathbb{P}_n$ are all $\mathbb{F}_+-$stopping times since the $H^\mathbb{P}$ are right-continuous and $\mathbb{F}_+-$adapted. We then define

$$
[H^\mathbb{P}]_t(\omega) := \limsup_{n \to +\infty} \sum_{i \geq 0} \left( H^\mathbb{P}_{\tau_i^\mathbb{P}_n}(\omega) - H^\mathbb{P}_{\tau_i^\mathbb{P}_n}(\omega) \right)^2.
$$

(2.16)

It is clear that $(\mathbb{P}, \omega, t) \mapsto [H^\mathbb{P}]_t(\omega)$ is a measurable function, and for all $\mathbb{P} \in \mathcal{P}$, $[H^\mathbb{P}]$ is non-decreasing, $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$optional. Then, it follows by Karandikar [47] that $[H^\mathbb{P}]$ coincides with the quadratic variation of the semi-martingale $H^\mathbb{P}$ under $\mathbb{P}$. Moreover, by taking its right limit over rational time instants, we can choose $[H^\mathbb{P}]$ to be right continuous.

(ii) Finally, using Proposition 5.1 of Neufeld and Nutz [60], we can then construct a process $\langle H^\mathbb{P}_t \rangle^\mathbb{P}(\omega)$ satisfying the required conditions.

Notice that the construction above can also be carried out for the predictable quadratic covariation $\langle H^{\mathbb{P},1}, H^{\mathbb{P},2} \rangle^\mathbb{P}$, by defining it through the polarization identity

$$
\langle H^{\mathbb{P},1}, H^{\mathbb{P},2} \rangle^\mathbb{P} := \frac{1}{4} \left( \langle H^{\mathbb{P},1} \rangle^\mathbb{P} - \langle H^{\mathbb{P},2} \rangle^\mathbb{P} \right),
$$

(2.17)

for all measurable functions $H^{\mathbb{P},1}_t(\omega)$ and $H^{\mathbb{P},2}_t(\omega)$ satisfying the conditions in Lemma 2.3.

We now show that the iteration in Section 2.4.2 can be taken in a measurable way w.r.t. $\mathbb{P}$, which provides a key step for the proof of Theorem 2.1.

**Lemma 2.4.** Let $m > 0$ be a fixed constant, $(s, \omega, \mathbb{P}) \mapsto (Y^\mathbb{P}_{s,n,m}(\omega), Z^\mathbb{P}_{s,n,m}(\omega))$ be a measurable map such that for every $\mathbb{P} \in \mathcal{P}_t$, $Y^\mathbb{P}_{s,n,m}$ is right-continuous, $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$optional, $Z^\mathbb{P}_{s,n,m}$ is $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$predictable. Then we can choose a measurable map $(s, \omega, \mathbb{P}) \mapsto (Y^\mathbb{P}_{s,n,m}(\omega), Z^\mathbb{P}_{s,n,m}(\omega))$ such that for every $\mathbb{P} \in \mathcal{P}_t$, $Y^\mathbb{P}_{s,n+1,m}$ is right-continuous, $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$optional, $Z^\mathbb{P}_{s,n+1,m}$ is $\mathbb{F}_+-$adapted and $\mathbb{F}_+^\mathbb{P}-$predictable.
Proof. (i) First, using Lemma 3.1 of Neufeld and Nutz [60], there is a version of \((\tilde{\mathcal{Y}}^{F,n+1,m})\) defined by (2.11), such that \((\mathbb{P}, \omega) \mapsto \tilde{\mathcal{Y}}^{F,n+1,m}_s(\omega)\) is \(\mathcal{B} \otimes \mathcal{F}_{s}\)-measurable for every \(s \in [t, T]\).

(ii) Next, we notice that the measurability is not lost by taking the limit along a countable sequence. Then with the above version of \((\mathcal{Y}^{F,n+1,m})\), it is clear that the family \((\mathcal{Y}^{F,n+1,m}(\omega))\) defined by (2.12) is measurable in \((s, \omega, \mathbb{P})\), and for all \(\mathbb{P} \in \mathcal{P}_t\), \(\mathcal{Y}^{F,n+1,m}\) is \(\mathbb{F}_+\)-adapted and \(\mathbb{F}_+\)-optional.

(iii) Then using Lemma 2.3 as well as the definition of the quadratic covariation in (2.17), it follows that there is a measurable function

\[
(s, \omega, \mathbb{P}) \mapsto \langle \mathcal{Y}^{F,n+1,m}, X \rangle^F_s(\omega),
\]

such that for every \(\mathbb{P} \in \mathcal{P}_t\), \(\langle \mathcal{Y}^{F,n+1,m}, X \rangle^F\) is right-continuous, \(\mathbb{F}_+\)-adapted and coincides with the predictable quadratic covariation of \(\mathcal{Y}^{F,n+1,m}\) and \(X\) under \(\mathbb{P}\).

(iv) Finally, with the above version of \((\langle \mathcal{Y}^{F,n+1,m}, X \rangle^F)\), it is clear that the family \((\tilde{\mathcal{Y}}^{F,n+1,m}(\omega))\) defined by (2.13) is measurable in \((s, \omega, \mathbb{P})\) and for every \(\mathbb{P} \in \mathcal{P}_t\), \(\tilde{\mathcal{Y}}^{F,n+1,m}\) is \(\mathbb{F}_+\)-adapted and \(\mathbb{F}_+\)-predictable. \(\square\)

Lemma 2.5. For every \(\mathbb{P} \in \mathcal{P}_t\), there is some right-continuous, \(\mathbb{F}_+^\mathbb{P}\)-martingale \(M^{F,n+1,m}\) orthogonal to \(X\) under \(\mathbb{P}\), such that \(\mathbb{P}\) – a.s.

\[
\mathcal{Y}^{F,n+1,m}_t = \xi - \int_t^T f(s, X_{\wedge s}, \mathcal{Y}^{F,n+1,m}_s, \tilde{a}_s^{1/2}, \mathcal{Z}^{F,n+1,m}_s, \tilde{a}_s, b^F_s)ds - \int_t^T \mathcal{Z}^{F,n+1,m}_s \cdot dX^c_s\mathbb{P}^\mathbb{P} + \int_t^T dM^{F,n+1,m}_s.
\]

(2.18)

Proof. Using Doob’s upcrossing inequality, the the limit \(\lim_{r \downarrow s} \mathcal{Y}^{F,n+1,m}_r\) exists \(\mathbb{P}\)–almost surely, for every \(\mathbb{P} \in \mathcal{P}_t\). In other words, \(\mathcal{Y}^{F,n+1,m}\) is version of the right continuous modification of \(\mathcal{Y}^{F,n+1,m}\). Then by the uniqueness of the martingale representation, we know (2.18) holds true. \(\square\)

Lemma 2.6. There are families of subsequences \((n^F_{k,1}, k \geq 1)\) and \((m^F_{i}, i \geq 1)\) such that the limit \(\mathcal{Y}^F_t(\omega) = \lim_{i \to \infty} \lim_{k \to \infty} \mathcal{Y}^{F,n_{k,m},m^F_{i}}\) exists for all \(s \in [t, T]\), \(\mathbb{P}\)–almost surely, for every \(\mathbb{P} \in \mathcal{P}_t\), and \((s, \omega, \mathbb{P}) \mapsto \mathcal{Y}^{F}_t(\omega)\) is a measurable function. Moreover, \(\mathcal{Y}^F_t\) provides a solution to the BSDE (2.5) for every \(\mathbb{P} \in \mathcal{P}_t\).

Proof. By integrability conditions in (2.4), \((\mathcal{Y}^{F,n,m}, \mathcal{Z}^{F,n,m})_{n \geq 1}\) provides a Picard iteration under the \((\mathbb{P}, \beta)\)-norm, for \(\beta > 0\) large enough (see e.g. Section 4 of [12]^2), defined by

\[
||\varphi||^2_{\mathbb{P}, \beta} := \mathbb{E}^\mathbb{P}\left[\sup_{t \leq s \leq T} e^{\beta s} ||\varphi||^2\right].
\]

Hence, \(\mathcal{Y}^{F,n,m}\) converges (under the \((\mathbb{P}, \beta)\)-norm) to some process \(\mathcal{Y}^{F,m}\) as \(n \to \infty\), which solves the BSDE (2.5) with the truncated terminal condition \(\xi^m\) and truncated generator \(f^m\). Moreover, by the estimates in Section 4 of [12] (see again Footnote 2), \((\mathcal{Y}^{F,m})_{m \geq 1}\) is a Cauchy sequence in \(\mathbb{D}^p_{t,\omega}(\mathbb{F}_+, \mathbb{P})\). Then using Lemma 3.2 of [60], we can find two families of subsequences \((n^F_{k,1}, k \geq 1, \mathbb{P} \in \mathcal{P}_t)\) and \((m^F_{i}, i \geq 1, \mathbb{P} \in \mathcal{P}_t)\) satisfying the required properties. \(\square\)

^2Again, we remind the reader that one should first apply the result of [12] to the corresponding Picard iteration of (2.9) in the enlarged space and then use Lemma 2.2 to go back to the original space.
2.4.4 End of the proof of Theorem 2.1

Now we can complete the proof of the dynamic programming in Theorem 2.1. Let us first provide a tower property for the BSDE (2.5).

**Lemma 2.7.** Let \((t, \omega) \in [0, T] \times \Omega, \mathbb{P} \in \mathcal{P}(t, \omega), \tau\) be an \(\mathbb{F}\)–stopping time taking values in \([t, T]\) and \((\mathcal{Y}^P, \mathcal{Z}^P, \mathcal{M}^P)\) be a solution to the BSDE (2.5) under \(\mathbb{P}\). Then one has

\[
\mathcal{Y}^P_t(T, \xi) = \mathcal{Y}^P_T(\tau, \mathcal{Y}^P_T) = \mathcal{Y}^P_T(\tau, \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}_\tau]), \quad \mathbb{P} - a.s.
\]

**Proof.** (i) Given a solution \((\mathcal{Y}^P, \mathcal{Z}^P, \mathcal{M}^P)\) to the BSDE (2.5) under \(\mathbb{P}\) w.r.t the filtration \(\mathcal{F}^P_+ = (\mathcal{F}^P_{s+})_{t \leq s \leq T}\), one then has

\[
\mathcal{Y}^P_t = \mathcal{Y}^P_T - \int_t^T f(s, X_s, \mathcal{Y}^P_s, \mathcal{Z}^P_s, \mathcal{M}^P_s) \, ds - \left(\int_t^T \mathcal{Z}^P_s \, dX^P_s\right)^P - \int_t^T d\mathcal{M}^P_s, \quad \mathbb{P} - a.s.,
\]

By taking conditional expectation w.r.t. \(\mathcal{F}^P_\tau\) under \(\mathbb{P}\), it follows that, \(\mathbb{P} - a.s.,

\[
\mathcal{Y}^P_t = \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}^P_\tau],
\]

where \(\tilde{\mathcal{M}}^P_\tau := \mathbb{E}^P[\mathcal{M}^P_T|\mathcal{F}^P_\tau]\), and \(\tilde{\mathcal{M}}^P_s := \mathcal{M}^P_s\) when \(s < \tau\). By identification, we deduce that \(\tilde{\mathcal{M}}^P_\tau = \mathcal{M}^P_\tau + \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}_\tau] - \mathcal{Y}^P_T\). Moreover, it is clear that \(\tilde{\mathcal{M}}^P \in \mathcal{M}^P_t(\mathbb{P}^P_+, \mathbb{P})\) and \(\tilde{\mathcal{M}}^P\) is orthogonal to the continuous martingale \(X\) under \(\mathbb{P}\).

(ii) Let us now consider the BSDE with generator \(f\) and terminal condition \(\mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}^P_\tau]\), on \([t, \tau]\). By uniqueness of the solution to BSDE, it follows that

\[
\mathcal{Y}^P_t(T, \xi) = \mathcal{Y}^P_t(\tau, \mathcal{Y}^P_T) = \mathcal{Y}^P_T(\tau, \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}_\tau]), \quad \mathbb{P} - a.s. \quad \square
\]

**Proof of Theorem 2.1.** (i) First, by the item (iii) of Assumption 2.1, it is clear that \(\hat{\mathcal{Y}}_t(\omega) = \hat{\mathcal{Y}}_t(\omega_{t\wedge \cdot})\). Moreover, since \((t, \omega, \mathbb{P}) \mapsto \mathcal{Y}^P_t(\omega)\) is a Borel measurable map from \([0, T] \times \Omega \times \mathcal{M}_1\) to \(\mathbb{R}\) by Lemma 2.6, and the graph \([\mathcal{P}]\) is also a Borel measurable in \([0, T] \times \Omega \times \mathcal{M}_1\) by Assumption 2.1, it follows by the measurable selection theorem that \((t, \omega) \mapsto \hat{\mathcal{Y}}_t(\omega)\) is \(\mathcal{B}([0, T]) \otimes \mathcal{F}_T\)–universally measurable (or more precisely upper semi-analytic, see e.g. Proposition 7.47 of Bertsekas and Shreve [5] or Theorem III.82 (P. 161) of Dellacherie and Meyer [24]).

(ii) Now, using the measurable selection argument, the DPP is a direct consequence of the comparison principle and the stability of BSDE (2.5). First, for every \(\mathbb{P} \in \mathcal{P}_t\), we have

\[
\mathcal{Y}^P_t(T, \xi) = \mathcal{Y}^P_t(\tau, \mathcal{Y}^P_T) = \mathcal{Y}^P_T(\tau, \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}_\tau]), \quad \mathbb{P} - a.s.
\]

It follows by the comparison principle of the BSDE (2.5) (see Lemma A.3 in Appendix together with Lemma 2.2) that

\[
\hat{\mathcal{Y}}_t(\omega) := \sup_{\mathbb{P} \in \mathcal{P}(t, \omega)} \mathbb{E}^P[\mathcal{Y}^P_t(T, \xi)] = \sup_{\mathbb{P} \in \mathcal{P}(t, \omega)} \mathbb{E}^P[\mathcal{Y}^P_T(\tau, \mathbb{E}^P[\mathcal{Y}^P_T|\mathcal{F}_\tau])] \leq \sup_{\mathbb{P} \in \mathcal{P}(t, \omega)} \mathcal{Y}^P_t(\tau, \hat{\mathcal{Y}}_\tau).
\]

Next, for every \(\mathbb{P} \in \mathcal{P}(t, \omega)\) and \(\varepsilon > 0\), using the measurable selection theorem (see e.g. Proposition 7.50 of [5] or Theorem III.82 in [24]), one can choose a family of probability measures \((\mathcal{Q}^w_\omega)_{w \in \Omega}\) such that \(w \mapsto \mathcal{Q}^w_\omega\) is \(\mathcal{F}_\tau\)–measurable, and for \(\mathbb{P} - a.e. w \in \Omega,

\[
\mathcal{Q}^w_\omega \in \mathcal{P}(\tau(w), w) \quad \text{and} \quad \mathbb{E}^{\mathcal{Q}^w_\omega}[\mathcal{Y}^{\mathcal{Q}^w_\omega}_{\tau(w)}(T, \xi)] \geq \hat{\mathcal{Y}}_{\tau(w)}(w) - \varepsilon.
\]
We can then define the concatenated probability \( \mathbb{P}^\varepsilon := \mathbb{P} \otimes_{\varepsilon} \mathbb{Q}^\varepsilon \) so that, by Assumption 2.1 (v), \( \mathbb{P}^\varepsilon \in \mathcal{P}(t, \omega) \). Finally, using the stability of the solution to BSDE (2.5) in Lemma A.1 (together with Lemma 2.2), it follows that

\[
\hat{Y}_t(\omega) \geq \mathbb{E}^{\mathbb{P}^\varepsilon} [\hat{Y}_\tau^{\mathbb{P}^\varepsilon}] = \mathbb{E}^{\mathbb{P}^\varepsilon} [\hat{Y}_\tau^{\mathbb{P}^\varepsilon} | \mathcal{F}_\tau] \geq \mathbb{E}^{\mathbb{P}^\varepsilon} [\hat{Y}_\tau^{\mathbb{P}^\varepsilon} (\tau, \hat{Y}_\tau)] - C\varepsilon,
\]

for some constant \( C > 0 \) independent of \( \varepsilon \). And hence the other inequality of the DPP holds true by the arbitrariness of \( \varepsilon > 0 \) as well as that of \( \mathbb{P} \in \mathcal{P}(t, \omega) \).

**2.4.5 Further discussions**

Notice that the essential arguments to prove the measurability of \( \hat{Y}_t(\omega) \) is to construct the solution of the BSDE in a measurable way with respect to different probabilities. Then the dynamic programming principle follows directly from the measurable selection theorem together with the comparison and stability of the BSDE. This general approach is not limited to BSDEs with Lipschitz generator. Indeed, the solution of any BSDEs that can be approximated by a countable sequence of Lipschitz BSDEs inherits directly the measurability property. More precisely, we have the following proposition which also applies to specific super-solutions (see Section 2.3 in [36] for a precise definition) of the BSDEs:

**Proposition 2.1.** Let \( Y^\mathbb{P} \) be the first component of the (minimal) super-solution of a BSDE with possibly non-Lipschitz generator. We have

1. If there is a family \( (Y^{\mathbb{P},n}) \), which corresponds to the first component of a family of Lipschitz BSDEs, and a family of subsequence \( (n_k^\mathbb{P})_{k \geq 1} \) such that, \( \mathbb{P} \mapsto n_k^\mathbb{P} \) is (Borel) measurable, and \( Y^{\mathbb{P}} = \lim_{k \to \infty} Y^{\mathbb{P},n_k} \). Then \((s, \omega, \mathbb{P}) \mapsto \hat{Y}_s(\omega) := \sup_{\mathbb{P} \in \mathcal{P}(s, \omega)} \mathbb{E}^{\mathbb{P}} [Y^\mathbb{P}_s] \) is a measurable map, and \((t, \omega) \mapsto \hat{Y}_t(\omega) \) is \( \mathcal{B}([0, T]) \otimes \mathcal{F}_T \)-universally measurable.

2. Furthermore, if the (possibly non-Lipschitz) BSDE for \( Y^\mathbb{P} \) admits the comparison principle and the stability result w.r.t. the terminal conditions, then for all \((t, \omega) \in [0, T] \times \Omega \) and \( \mathbb{F} \)-stopping times \( \tau \) taking value in \([t, T] \), we have

\[
\hat{Y}_t(\omega) = \sup_{\mathbb{P} \in \mathcal{P}(t, \omega)} \mathbb{E}^{\mathbb{P}} [Y^\mathbb{P}_\tau (\tau, \hat{Y}_\tau)] .
\]

In particular, this result can be applied to BSDEs with linear growth [53], to BSDEs with general growth in \( y \) [67], to quadratic BSDEs [3, 50], to BSDEs with unbounded horizon [22], to reflected BSDEs [34], to constrained BSDEs [18, 69] (for the point (i) only),...

**Remark 2.3.** In Assumption 2.1, the terminal condition \( \xi : \Omega \to \mathbb{R} \) is assumed to be Borel measurable, which is more restrictive comparing to the results in the context of controlled diffusion/jump process problems (where \( \xi \) is only assumed to be upper semi-analytic, see e.g. [59] or [37]). This Borel measurability condition is however crucial in our BSDE context. For example, when \( f(t, \omega, y, z, a, b) = \|z| \), we know the solution of the BSDE (2.5) is given by \( \inf_{\hat{\mathbb{P}} \in \hat{\mathbb{P}}} \mathbb{E}^{\hat{\mathbb{P}}} [\xi] \) for some family \( \hat{\mathbb{P}} \) of probability measure equivalent to \( \mathbb{P} \). However, as is well known, the upper-semianalytic property is stable by taking supremum but not by taking infimum.
3 Path regularization of the value function

In this section, we will characterize a càdlàg modification of the value function \( \hat{Y} \) as a semi-martingale under any \( \mathbb{P} \in \mathcal{P}_0 \) and give its decomposition. In the next section, we will show that this càdlàg modification of the value function \( \hat{Y} \) is the solution to some second order BSDE defined there (see Definition 4.1).

First of all, we recall from Theorem 2.1 that we have for any \( \mathbb{F} \)-stopping times \( \tau \geq \sigma \)
\[
\hat{Y}_{\sigma(\omega)}(\omega) = \sup_{\mathbb{P} \in \mathcal{P}(\sigma(\omega), \omega)} \mathbb{E}^\mathbb{P} \left[ Y^\mathbb{P}_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right].
\] (3.1)

Moreover, we also have
\[
\hat{Y}_{\sigma(\omega)}(\omega) = \sup_{\mathbb{P} \in \mathcal{P}(\sigma(\omega), \omega)} \mathbb{E}^{\mathbb{P} \otimes \mathbb{P}_0} \left[ \tilde{Y}^\mathbb{P} \otimes \mathbb{P}_0_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right],
\] (3.2)

where \( \tilde{Y}^\mathbb{P} \otimes \mathbb{P}_0_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \) is the equivalent of \( Y^\mathbb{P}_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \) but defined on the enlarged space, recall (2.9) and Lemma 2.2.

Let us start with the following technical lemma. Formally, it can be obtained by simply taking conditional expectations of the corresponding BSDEs. However, this raises subtle problems about negligible sets and conditional probability measures. We therefore refer the reader to [14] for the precise details.

**Lemma 3.1.** For any \( \mathbb{P} \in \mathcal{P}_0 \), for any \( \mathbb{F} \)-stopping times \( 0 \leq \sigma \leq \tau \leq T \), we have
\[
\mathbb{E}^{\mathbb{P}^0(\omega) \otimes \mathbb{P}_0} \left[ \tilde{Y}^\mathbb{P}^0_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right] = \mathbb{E}^{\mathbb{P} \otimes \mathbb{P}_0} \left[ Y^\mathbb{P}_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right] \left( \mathcal{F}_\sigma \right)(\omega, \omega'), \text{ for } \mathbb{P} \otimes \mathbb{P}_0 - \text{a.e. } (\omega, \omega') \in \Omega,
\]
\[
\mathbb{E}^{\mathbb{P}^0(\omega)} \left[ \tilde{Y}^\mathbb{P}^0_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right] = \mathbb{E}^{\mathbb{P}} \left[ Y^\mathbb{P}_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right] \left( \mathcal{F}_\sigma \right)(\omega), \text{ for } \mathbb{P} - \text{a.e. } \omega \in \Omega.
\]

Let us next remark the following immediate consequences of the above equations
\[
\hat{Y}_{\sigma(\omega)} \geq \mathbb{E}^{\mathbb{P}} \left[ Y^\mathbb{P}_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right], \text{ for any } \mathbb{P} \in \mathcal{P}(\sigma(\omega), \omega),
\] (3.3)
\[
\hat{Y}_{\sigma(\omega)} \geq \mathbb{E}^{\mathbb{P} \otimes \mathbb{P}_0} \left[ \tilde{Y}^\mathbb{P} \otimes \mathbb{P}_0_{\sigma(\omega)}(\tau, \hat{Y}_\tau) \right], \text{ for any } \mathbb{P} \in \mathcal{P}(\sigma(\omega), \omega).
\] (3.4)

With these inequalities, we can prove a downcrossing inequality for \( \hat{Y} \), which ensures that \( \hat{Y} \) admits right- and left-limits outside a \( \mathcal{P}_0 \)-polar set.

Recall that
\[
\tilde{F}_s^\mathbb{P}(y, z) := f(s, X, \omega, y, z, \hat{a}_s, b^\mathbb{P}_s), \quad \tilde{F}_s^\mathbb{P} := f(s, X, \omega, 0, 0, \hat{a}_s, b_s^\mathbb{P}).
\]

Let \( J := (\tau_n)_{n \in \mathbb{N}} \) be a countable family of \( \mathbb{F} \)-stopping times taking values in \([0, T]\) such that for any \((i, j) \in \mathbb{N}^2\), one has either \( \tau_i \leq \tau_j \), or \( \tau_i \geq \tau_j \), for every \( \omega \in \Omega \). Let \( a > b \) and \( J_n \subset J \) be a finite subset \( J_n = \{ 0 \leq \tau_1 \leq \cdots \leq \tau_n \leq T \} \). We denote by \( D_a^b(\hat{Y}, J_n) \) the number of downcrossings of the process \( (\hat{Y}_{\tau_k})_{1 \leq k \leq n} \) from \( b \) to \( a \). We then define
\[
D_a^b(\hat{Y}, J) := \sup \{ D_a^b(\hat{Y}, J_n) : J_n \subset J, \text{ and } J_n \text{ is a finite set} \}.
\]

The following lemma follows very closely the related result proved in Lemma A.1 of [11]. However, since \( \hat{Y} \) is not exactly an \( \mathcal{E}^\mathbb{P} \)-supermartingale in their terminology, we give a short proof.
Lemma 3.2. Fix some \( P \in \mathcal{P}_0 \). Let Assumptions 2.1 and 3.1 hold. Denote by \( L \) the Lipschitz constant of the generator \( f \). Then, for all \( a < b \), there exists a probability measure \( \tilde{P} \), equivalent to \( P \otimes P_0 \), such that

\[
\mathbb{E}^{\tilde{P}} \left[ \sum_{T}^b D_a^{b} (\hat{Y}, J) \right] \leq \frac{e^{LT}}{b-a} \mathbb{E}^{\tilde{P}} \left[ e^{LT} (\hat{Y}_0 \wedge b-a) - e^{-LT} (\hat{Y}_T \wedge b-a) + e^{LT} \int_0^T \left| \hat{P}_s (a, 0) \right| ds \right].
\]

Moreover, outside a \( \mathcal{P}_0 \)-polar set, we have

\[
\lim_{r \in \mathcal{Q} \cap (t,T), r \downarrow t} \hat{Y}_r (\omega) = \lim_{r \in \mathcal{Q} \cap (t,T), r \uparrow T} \hat{Y}_r (\omega), \quad \text{and} \quad \lim_{r \in \mathcal{Q} \cap (t,T), r \uparrow t} \hat{Y}_r (\omega) = \lim_{r \in \mathcal{Q} \cap (t,T), r \downarrow t} \hat{Y}_r (\omega).
\]

**Proof.** Without loss of generality, we can always suppose that \( 0 = T \) belong to \( J \) and \( b > a = 0 \). Let \( J_n = \{ \tau_0, \tau_1, \ldots, \tau_n \} \) with \( 0 = \tau_0 < \tau_1 < \cdots < \tau_n = T \). We then consider for any \( i = 1, \ldots, n \), and any \( \omega \in \Omega \), the following BSDE in the enlarged space under \( \mathbb{P}_{T-}^{\tau_i-1}(\omega) := \mathbb{P}_{T-}^{\tau_i-1}(\omega) \otimes P_0 \) on \( [\tau_{i-1}, \tau_i] \)

\[
\hat{Y}_{t}^{\tau_i-1}(\omega) := \hat{Y}_{\tau_i} - \int_0^{\tau_i} \left( \frac{\hat{P}_s^{\tau_i-1}(\omega),0}{\hat{P}_s^{\tau_i-1}(\omega)} + \lambda s \hat{Y}_s^{\tau_i-1}(\omega) + \eta s \cdot \hat{Z}_s^{\tau_i-1}(\omega) \right) \hat{P}_s^{\tau_i-1}(\omega) ds
\]

where \( \lambda^i \) and \( \eta^i \) are the two bounded processes appearing in the linearization of \( \hat{f} \) (remember Assumption 2.1(i)). We consider then the linear BSDE, also on the enlarged space

\[
\hat{Y}_{t}^{\tau_i-1}(\omega) := \hat{Y}_{\tau_i} - \int_0^{\tau_i} \left( \frac{\hat{P}_s^{\tau_i-1}(\omega),0}{\hat{P}_s^{\tau_i-1}(\omega)} + \lambda \hat{Y}_s^{\tau_i-1}(\omega) + \eta s \cdot \hat{Z}_s^{\tau_i-1}(\omega) \right) \hat{P}_s^{\tau_i-1}(\omega) ds
\]

It is immediate that

\[
\mathbb{E}^{\hat{P}_{\tau_i-1}} \left[ L_{\tau_i} \left( \hat{Y}_{\tau_i} e^{\int_{\tau_i}^T \lambda ds} - \int_{\tau_i}^T e^{\int_{\tau_i}^s \lambda ds} \left| \hat{P}_s^{\tau_i-1}(\omega) \right| ds \right) \right] \leq \mathbb{E}^{\hat{P}_{\tau_i-1}} \left[ L_{\tau_i} \left( \hat{Y}_{\tau_i} e^{\int_{\tau_i}^T \lambda ds} - \int_{\tau_i}^T e^{\int_{\tau_i}^s \lambda ds} \left| \hat{P}_s^{\tau_i-1}(\omega) \right| ds \right) \right] \leq \hat{Y}_{\tau_i-1}(\omega), \quad P \otimes P_0 - a.s.
\]

By Assumption 2.1(iv), for \( P \) a.e. \( \omega \in \Omega \), \( \mathbb{P}_{\tau_i-1}(\omega) \cap \mathcal{P}(\tau_i-1)(\omega), \omega \). Hence, by the comparison principle for BSDEs, recalled in Lemma A.3 below, and (3.2), it is clear that

\[
\mathbb{E}^{\hat{P}_{\tau_i-1}} \left[ L_{\tau_i} \left( \hat{Y}_{\tau_i} e^{\int_{\tau_i}^T \lambda ds} - \int_{\tau_i}^T e^{\int_{\tau_i}^s \lambda ds} \left| \hat{P}_s^{\tau_i-1}(\omega) \right| ds \right) \right] \leq \hat{Y}_{\tau_i-1}(\omega).
\]

But, by definition of the r.p.c.d., this implies that

\[
\mathbb{E}^{\tilde{P}} \left[ \hat{Y}_{\tau_i} e^{\int_{\tau_i}^T \lambda ds} - \int_{\tau_i}^T e^{\int_{\tau_i}^s \lambda ds} \left| \hat{P}_s^{\tau_i-1}(\omega) \right| ds \right] \leq \hat{Y}_{\tau_i-1}, \quad P \otimes P_0 - a.s.,
\]

19
where the probability measure \( \mathbb{Q} \) is equivalent to \( \mathbb{P} \otimes \mathbb{P}_0 \) and defined by
\[
\frac{d\mathbb{Q}}{d\mathbb{P} \otimes \mathbb{P}_0} := \mathcal{E} \left( \int_{\tau_{i-1}}^{t} \eta^i_s \cdot dW^p_s \right), \quad t \in [\tau_{i-1}, \tau_i].
\]
Let \( \lambda_i := \sum_{n=1}^N \lambda^i_n 1_{[\tau_{i-1}, \tau_i)}(s) \), then one has that the discrete process \((V_{\tau_i})_{0 \leq i \leq n}\) defined by
\[
V_{\tau_i} := \hat{\mathcal{Y}}_{\tau_i} e^{\int_{0}^{\tau_i} \lambda_s ds} - \int_{0}^{\tau_i} e^{\int_{0}^{r} \lambda_s dr} \mathbb{E}_s[r, 0] ds,
\]
is a \( \mathbb{Q} \)-supermartingale relative to \( \mathbb{F} \). Then, the control on the downcrossings can be obtained exactly as in the proof of Lemma A.1 in [11]. Indeed, it is enough to observe that the original downcrossing inequality for supermartingales (see e.g. [27][p.446]) does not require the filtration to satisfy the usual assumptions. We now prove the second part of the lemma. We define the set
\[
\Sigma := \{ \omega \in \Omega \text{ s.t. } \hat{\mathcal{Y}}(\omega) \text{ has no right- or left-limits along the rationals} \}.
\]
We claim that \( \Sigma \) is a \( \mathcal{P}_0 \)-polar set. Indeed, suppose that there exists \( \mathbb{P} \in \mathcal{P}_0 \) satisfying \( \mathbb{P}(\Sigma) > 0 \). Then, \( \Sigma \) is non-empty and for any \( \omega \in \Sigma \), the path \( \hat{\mathcal{Y}}(\omega) \) has, e.g., no right-limit along the rationals at some point \( t \in [0, T] \). We can therefore find two rational numbers \( a, b \) such that
\[
\lim_{r \in \mathbb{Q} \cap (t, T], r \downarrow t} \hat{\mathcal{Y}}_r(\omega) < a < b < \lim_{r \in \mathbb{Q} \cap (t, T], r \uparrow t} \hat{\mathcal{Y}}_r(\omega),
\]
and the number of downcrossing \( D^b_{a}(\hat{\mathcal{Y}}, J)(\omega) \) of the path \( \hat{\mathcal{Y}}(\omega) \) on the interval \([a, b]\) is equal to \(+\infty\). However, the downcrossing inequality proved above shows that \( D^b_{a}(\hat{\mathcal{Y}}, J) \) is \( \mathbb{Q} \)-a.s., and thus \( \mathbb{P} \)-a.s. (see Lemma 2.1), finite, for any pair \((a, b)\). This implies a contradiction since we assumed that \( \mathbb{P}(\Sigma) > 0 \). Therefore, outside the \( \mathcal{P}_0 \)-polar set \( \Sigma \), \( \hat{\mathcal{Y}} \) admits both right- and left-limits along the rationals.

We next define for all \((t, \omega) \in [0, T) \times \Omega\)
\[
\hat{\mathcal{Y}}^+_t := \lim_{r \in \mathbb{Q} \cap (t, T], r \downarrow t} \hat{\mathcal{Y}}_r, \quad (3.5)
\]
and \( \hat{\mathcal{Y}}^+_T := \hat{\mathcal{Y}}_T \). By Lemma 3.2,
\[
\hat{\mathcal{Y}}^+_t := \lim_{r \in \mathbb{Q} \cap (t, T], r \uparrow t} \hat{\mathcal{Y}}_r, \text{ outside a } \mathcal{P}_0 \text{-polar set,}
\]
and we deduce that \( \hat{\mathcal{Y}}^+ \) is càd outside a \( \mathcal{P}_0 \)-polar set. Hence, since for any \( t \in [0, T] \), \( \hat{\mathcal{Y}}^+_t \) is by definition \( \mathcal{F}^U_t \)-measurable, we deduce that \( \hat{\mathcal{Y}}^+ \) is actually \( \mathbb{P}^{\mathcal{P}_0^+} \)-optional. Our next result extends (3.3) to \( \hat{\mathcal{Y}}^+ \).

**Lemma 3.3.** For any \( 0 \leq s \leq t \leq T \), for any \( \mathbb{P} \in \mathcal{P}_0 \), we have
\[
\mathbb{E}_s^{\mathbb{P}}[\hat{\mathcal{Y}}_{s}^+ (t, \hat{\mathcal{Y}}^+_t)] \geq \mathcal{Y}_{n}^+(t, \hat{\mathcal{Y}}^+_t), \quad \mathbb{P} \text{ - a.s.}
\]

**Proof.** Fix some \((s, t, \omega) \in [0, T] \times [s, T] \times \Omega\) and some \( \mathbb{P} \in \mathcal{P}_0 \). Let \( r^1_n \in \mathbb{Q} \cap (s, T), r^1_n \downarrow s \) and \( r^2_n \in \mathbb{Q} \cap (t, T), r^2_n \downarrow t \). By (3.3), we have for any \( m, n \geq 1 \) and \( \mathbb{P} \in \mathcal{P}(r^1_n, \omega) \)
\[
\hat{\mathcal{Y}}_{r^1_n}^+(s, \omega) \geq \mathbb{E}_s^{\mathbb{P}} \left[ \mathcal{Y}_{r^1_n}^+(r^2_n, \hat{\mathcal{Y}}^+_t) \right].
\]
In particular, thanks to Assumption 2.1(iv), for \( P - \text{a.e. } \omega \in \Omega \), we have

\[
\hat{Y}_{i,n}^r(\omega) \geq \mathbb{E}^P[\mathcal{Y}_{r_i}^{p_1}(r_m^2, \hat{Y}_{r_i}^m)] = \mathbb{E}^P[\mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m)](\omega),
\]

where we have used Lemma 3.1.

By definition, we have

\[
\lim_{n \to +\infty} \hat{Y}_{i,n}^r = \hat{Y}_{i}^r, \quad P - \text{a.s.}
\]

Next, we want to show that

\[
\mathbb{E}^P[\mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m)|\mathcal{F}_{r_i}^n] \to \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m), \quad \text{for the norm } \| \cdot \|_{L_{s,\omega}^2}.
\]

Indeed, we have

\[
\mathbb{E}^P\left[\left| \mathbb{E}^P\left[\mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m)|\mathcal{F}_{r_i}^n\right] - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \right| \right] = \mathbb{E}^P\left[\left| \mathbb{E}^P\left[\mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m)|\mathcal{F}_{r_i}^n\right] \right| \right] \leq \mathbb{E}^P\left[\left| \mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \right| \right] \mathbb{E}^P[\mathcal{F}_{r_i}^n] = \mathbb{E}^P\left[\left| \mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \right| \right].
\]

Then, since \( \mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \) is càdlàg, we know that \( \mathcal{Y}_{r_i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \) goes, \( P - \text{a.s.} \), to \( \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \), as \( n \) goes to \( +\infty \). Moreover, by the estimates of Lemma A.1 (together with Lemma 2.2), the quantity in the expectation above is uniformly bounded in \( L^p(\mathcal{F}_{r_i}^n, P) \), and therefore forms a uniformly integrable family by de la Vallée-Poussin criterion (since \( p > 1 \)). Therefore the desired convergence is a simple consequence of the dominated convergence theorem. Hence, taking a subsequence if necessary, we have that the right-hand side of (3.6) goes \( P - \text{a.s} \) to \( \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \) as \( n \) goes to \( +\infty \), so that we have

\[
\hat{Y}_{i}^r \geq \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m), \quad P - \text{a.s.}
\]

Next, we have by the dynamic programming for BSDEs

\[
\mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) - \mathcal{Y}_{s}^{p_2}(t, \hat{Y}_{i}^r) = \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) + \mathcal{Y}_{s}^{p_2}(t, \mathcal{Y}_{i}^{p_2}(r_m^2, \hat{Y}_{r_i}^m)) - \mathcal{Y}_{s}^{p_2}(t, \hat{Y}_{i}^r).
\]

The first difference on the right-hand side converges to 0, \( P - \text{a.s.} \), once more thanks to the estimates of Lemma A.1 (together with Lemma 2.2) and the definition of \( \hat{Y}_{i}^r \). As for the second difference, the same estimates show that it is controlled by

\[
\mathbb{E}^P\left[\left| \mathcal{Y}_{i}^{p_2} - \mathcal{Y}_{s}^{p_2}(r_m^2, \hat{Y}_{r_i}^m) \right|^{\tilde{p}}\right],
\]

for some \( 1 < \tilde{p} < p \). This term goes \( P - \text{a.s.} \) (at least along a subsequence) to 0 as \( m \) goes to \( +\infty \) as well by Lemma A.2 (together with Lemma 2.2), which ends the proof. \( \square \)

The next lemma follows the classical proof of the optional sampling theorem for càdlàg supermartingales and extends the previous result to stopping times.
Lemma 3.4. For any $\mathbb{P}$–stopping times $0 \leq \sigma \leq \tau \leq T$, for any $\mathbb{P} \in \mathcal{P}_0$, we have

$$\hat{Y}^+_\sigma \geq Y^+_\sigma(\tau, \hat{Y}^+_\tau), \ \mathbb{P} - \text{a.s.}$$

In particular $\hat{Y}^+$ is càdlàg, $\mathcal{P}_0$–q.s.

Proof. Assume first that $\sigma$ takes a finite number of values $\{t_1, \ldots, t_n\}$ and that $\tau$ is deterministic. Then, we have for any $\mathbb{P} \in \mathcal{P}_0$

$$\hat{Y}^+_\sigma = \sum_{i=1}^{n} \hat{Y}^+_t 1_{\{\sigma = t_i\}} \geq \sum_{i=1}^{n} Y^+_t(\tau, \hat{Y}^+_\tau) 1_{\{\sigma = t_i\}} = Y^+_\sigma(\tau, \hat{Y}^+_\tau), \ \mathbb{P} - \text{a.s.}$$

Assume next that both $\tau$ and $\sigma$ take a finite number of values $\{t_1, \ldots, t_n\}$. We have similarly

$$Y^+_\sigma(\tau, \hat{Y}^+_\tau) = \sum_{i=1}^{n} Y^+_\sigma(t_i, \hat{Y}^+_\tau) 1_{\{\tau = t_i\}} \leq \sum_{i=1}^{n} \hat{Y}^+_t 1_{\{\tau = t_i\}} = \hat{Y}^+_\sigma, \ \mathbb{P} - \text{a.s.}$$

Then, if $\sigma$ is general, we can always approach it from above by a decreasing sequence of $\mathbb{P}^+$–stopping times $(\sigma^n)_{n \geq 1}$ taking only a finite number of values. The above results imply directly that

$$\hat{Y}^+_{\sigma^n \land \tau} \geq Y^+_{\sigma^n \land \tau}(\tau, \hat{Y}^+_\tau), \ \mathbb{P} - \text{a.s.}$$

Then, we can use the right-continuity of $\hat{Y}^+$ and $Y^+_\sigma(\tau, \hat{Y}^+_\tau)$ to let $n$ go to $+\infty$ and obtain

$$\hat{Y}^+_\sigma \geq Y^+_\sigma(\tau, \hat{Y}^+_\tau), \ \mathbb{P} - \text{a.s.}$$

Finally, let us take a general stopping time $\tau$. We once more approach it by a decreasing sequence of $\mathbb{P}^+$–stopping times $(\tau^n)_{n \geq 1}$ taking only a finite number of values. We thus have

$$\hat{Y}^+_\sigma \geq Y^+_\sigma(\tau^n, \hat{Y}^+_\tau^n), \ \mathbb{P} - \text{a.s.}$$

The term on the right-hand side converges (along a subsequence if necessary) $\mathbb{P} - \text{a.s.}$ to $Y^+_\sigma(\tau, \hat{Y}^+_\tau)$ by Lemma A.2 (together with Lemma 2.2).

It remains to justify that $\hat{Y}^+$ admits left–limits outside a $\mathcal{P}_0$–polar set. Fix some $\mathbb{P} \in \mathcal{P}_0$. Following the same arguments as in the proof of Lemma 3.2, we can show that for some probability measure $\overline{\mathbb{Q}}$ equivalent to $\mathbb{P} \otimes \mathbb{P}_0$ and some bounded process $\lambda$,

$$V_t := \hat{Y}_t e^{\int_0^t \lambda_s \lambda_s ds} - \int_0^t e^{\int_0^s \lambda_u ds} \hat{P}^{\mathbb{P},0}_s \left| \hat{Y}^+_s \right| ds,$$

is a right-continuous $(\overline{\mathbb{Q}}, \mathbb{P}^+)$–supermartingale, which is in addition uniformly integrable under $\overline{\mathbb{Q}}$ since $\hat{Y}$ and $\hat{P}^{\mathbb{P},0}$ are uniformly bounded in $L^p(\mathcal{F}_T, \mathbb{P} \otimes \mathbb{P}_0)$ and thus in $L^p(\mathcal{F}_T, \overline{\mathbb{Q}})$ for some $1 < \tilde{p} < p$. Therefore, for any increasing sequence of $\mathbb{P}^+$–stopping times $(\rho_n)_{n \geq 0}$ taking values in $[0, T]$, the sequence $(E^{\overline{\mathbb{Q}}}[V_{\rho_n}])_{n \geq 0}$ is non-increasing and admits a limit. By Theorem VI-48 and Remark VI-50(f) of [24], we deduce that $V$, and thus $\hat{Y}^+$, admit left-limits outside a $\overline{\mathbb{Q}}$–negligible (and thus $\mathbb{P}$–negligible by Lemma 2.1) set. Moreover, the above implies that the set

$$\left\{ \omega \in \Omega, \ \hat{Y}^+(\omega) \text{ admits left–limits} \right\},$$

is $\mathcal{P}_0$–polar, which ends the proof. \hfill \Box

Our next result shows that $\hat{Y}^+$ satisfies the representation formula (4.3). Part of it requires the following stronger integrability assumption
Assumption 3.1. There is some $\kappa \in (1, p]$ such that

$$
\phi_{f, \kappa}^p := \sup_{P \in P_0} \mathbb{E}^P \left[ \text{ess sup}_{0 \leq t \leq T} \left( \mathbb{E}^P \left[ \int_0^T |\hat{r}_{f,0}^P(\sigma)| \mathcal{F}_t \right] \right)^{\frac{\kappa}{p}} \right] < +\infty.
$$

Lemma 3.5. For any $\mathcal{F}$-stopping times $0 \leq \sigma \leq \tau \leq T$, for any $0 \leq t \leq T$, for any $P \in P_0$, we have

$$
\hat{Y}_\sigma = \text{ess sup}_{P' \in P_0(\sigma, P, \mathcal{F})} \mathbb{E}^{P'} \left[ Y_{\sigma}^{P'}(\tau, Y_{\tau}^{P'}) \right] \mathcal{F}_\sigma, \; P - a.s., \text{ and } \hat{Y}_t^+ = \text{ess sup}_{P' \in P_0(t, P, \mathcal{F}_+)} \mathbb{E}^{P'} \left[ Y_{t}^{P'}(T, \xi) \right], \; P - a.s.,
$$

where $P_0(\sigma, P, \mathcal{F})$ is defined in Section 2.2. In particular, if Assumption 3.1 holds, one has $\hat{Y}_t^+ \in \mathcal{D}_0^0(\mathbb{P}P_0^+)$. 

Proof. We start with the first equality. By definition and Lemma 3.1, for any $P' \in P_0(\sigma, P, \mathcal{F})$ we have

$$
\hat{Y}_\sigma \geq \mathbb{E}^{P'} \left[ Y_{\sigma}^{P'}(\tau, Y_{\tau}^{P'}) \right] \mathcal{F}_\sigma, \; P - a.s.
$$

But since both sides of the inequality are $\mathcal{F}_\sigma^U$-measurable and $P'$ coincides with $P$ on $\mathcal{F}_\sigma$ (and thus on $\mathcal{F}_\sigma^U$, by uniqueness of universal completion) the above also holds $P - a.s.$ We deduce

$$
\hat{Y}_\sigma \geq \text{ess sup}_{P' \in P_0(\sigma, P, \mathcal{F})} \mathbb{E}^{P'} \left[ Y_{\sigma}^{P'}(\tau, Y_{\tau}^{P'}) \right] \mathcal{F}_\sigma, \; P - a.s.
$$

Next, notice that by Lemmas 2.6 and 2.7, $(t, \omega, \mathcal{Q}) \longmapsto \mathbb{E}^{\mathcal{Q}} \left[ Y_{t}^{\mathcal{Q}}(T, \xi) \right] = \mathbb{E}^{\mathcal{Q}} \left[ Y_{t}^{\mathcal{Q}}(\tau, Y_{\tau}^{\mathcal{Q}}) \right]$ is Borel measurable. As in the proof of Theorem 2.1, it follows by the measurable selection theorem (see e.g. Proposition 7.47 of [5]) that for every $\varepsilon > 0$, there is a family of probability measure $(Q_\varepsilon^w)_{w \in \Omega}$ such that $w \mapsto Q_\varepsilon^w$ is $\mathcal{F}_\sigma$ measurable and for $P - a.e. \; w \in \Omega$,

$$
\hat{Y}_{\sigma(w)}(w) \leq \mathbb{E}^{Q_\varepsilon^w} \left[ Y_{\sigma(w)}^{Q_\varepsilon^w} \right] + \varepsilon, \; P - a.s.
$$

Let us now define the concatenated probability $P^\varepsilon := P \otimes_\sigma Q_\varepsilon^w$ so that $P^\varepsilon \in P_0(\sigma, P, \mathcal{F})$, it follows then by Lemma 3.1 that

$$
Y_{\sigma} \leq \mathbb{E}^{P^\varepsilon} \left[ Y_{\sigma}^{P} (\tau, Y_{\tau}^{P}) \right] \mathcal{F}_\sigma + \varepsilon \leq \text{ess sup}_{P' \in P_0(\sigma, P, \mathcal{F})} \mathbb{E}^{P'} \left[ Y_{\sigma}^{P'} (\tau, Y_{\tau}^{P'}) \right] \mathcal{F}_\sigma + \varepsilon, \; P - a.s.
$$

We hence finish the proof of the first equality by arbitrariness of $\varepsilon > 0$.

Let us now prove the second equality. Let $r_n^1 \in \mathcal{Q} \cap (t, T], r_n^1 \downarrow t$. By the first part of the proof, we have

$$
\hat{Y}_{r_n^1} = \text{ess sup}_{P' \in P_0(r_n^1, P, \mathcal{F})} \mathbb{E}^{P'} \left[ Y_{r_n^1}^{P'} (T, \xi) \right] \mathcal{F}_{r_n^1}, \; P - a.s.
$$

Since for every $n \in \mathbb{N}$, $P_0(r_n^1, P, \mathcal{F}) \subset P_0(t, P, \mathcal{F}_+)$, we deduce as above that for any $P' \in P_0(t, P, \mathcal{F}_+)$ and for $n$ large enough

$$
\hat{Y}_{r_n^1}^+ \geq \mathbb{E}^{P'} \left[ Y_{r_n^1}^{P'} (T, \xi) \right] \mathcal{F}_{r_n^1}, \; P - a.s.
$$

Arguing exactly as in the proof of Lemma 3.3, we can let $n$ go to $+ \infty$ to obtain

$$
\hat{Y}_t^+ \geq Y_{t}^{P'} (T, \xi), \; P - a.s.,
$$
which implies by arbitrariness of $\mathbb{P}'$,

$$
\hat{Y}_t^+ \geq \esssup_{\mathbb{P}' \in \mathcal{P}_0(t, \mathbb{P}, \mathbb{P}^+)} \mathcal{Y}_t^{\mathbb{P}'}(T, \xi), \ \mathbb{P} - a.s.
$$

We claim next that for any $n \in \mathbb{N}$, the following family is upward directed

$$
\left\{ \mathbb{E}^{\mathbb{P}'}_{\mathbb{P}} \left[ \mathcal{Y}_{r_n}^{\mathbb{P}'}(T, \mathcal{Y}_{r_n}^{\mathbb{P}'}) \mid \mathcal{F}_{r_n} \right], \ \mathbb{P}' \in \mathcal{P}_0(r_n, \mathbb{P}, \mathbb{P}) \right\}.
$$

Indeed this can be proved exactly as in Step 2 of the proof of Theorem 4.2. According to [61], we then know that there exists some sequence $(\mathbb{P}_m^m)_{m \geq 0} \subset \mathcal{P}_0(r_n, \mathbb{P}, \mathbb{P})$ such that

$$
\hat{Y}_{r_n} = \lim_{m \to +\infty} \uparrow \mathbb{E}^{\mathbb{P}_m} \left[ \mathcal{Y}_{r_n}^{\mathbb{P}_m}(T, \xi) \mid \mathcal{F}_{r_n} \right], \ \mathbb{P} - a.s.
$$

By dominated convergence (recall that the $\mathcal{Y}_{\mathbb{P}}$ are in $\mathbb{D}_0^p(\mathbb{F}^+, \mathbb{P})$, with a norm independent of $\mathbb{P}$, by Lemma A.1), the above convergence also holds for the $L^{\mathbb{P}_0(\mathbb{P})}$-norm, for any $1 < \bar{p} < p$. By the stability result of Lemma A.1 (together with Lemma 2.2) and the monotone convergence theorem, we deduce that

$$
\mathcal{Y}_t^{\mathbb{P}'}(r_n, \hat{Y}_{r_n}) = \mathcal{Y}_t^{\mathbb{P}'} \left( r_n, \lim_{m \to +\infty} \uparrow \mathbb{E}^{\mathbb{P}_m} \left[ \mathcal{Y}_{r_n}^{\mathbb{P}_m}(T, \xi) \mid \mathcal{F}_{r_n} \right] \right), \ \mathbb{P} - a.s.
$$

where we have used in the third equality the fact that $\mathbb{P}_m^m$ coincides with $\mathbb{P}$ on $\mathcal{F}_{r_n}$ and that $\mathcal{Y}_t^{\mathbb{P}_m}$ is $\mathcal{F}_{r_n}^+$-measurable, Lemma 2.7 in the fourth equality, and the dynamic programming principle for BSDEs in the fifth equality.

Finally, it remains to let $n$ go to $+\infty$ and to use Lemma A.2 (together with Lemma 2.2) to obtain the desired equality, from which we deduce exactly as in the proof of Theorem 4.3 that $\hat{Y}^+ \in \mathbb{D}_0^p(\mathbb{F}^0 \mathbb{P})$. \hfill $\square$

The next result shows that $\hat{Y}^+$ is actually a semi-martingale under any $\mathbb{P} \in \mathcal{P}_0$, and gives its decomposition.

**Lemma 3.6.** Let Assumptions 2.1 and 3.1 hold. For any $\mathbb{P} \in \mathcal{P}_0$, there exists $(Z^\mathbb{P}, M^\mathbb{P}, K^\mathbb{P}) \in \mathbb{H}_0^p(\mathbb{F}^+, \mathbb{P}) \times \mathbb{M}_0^p(\mathbb{F}^+, \mathbb{P}) \times \mathbb{L}_0^p(\mathbb{F}^+ \mathbb{P})$ and

$$
\hat{Y}_t^+ = \xi - \int_t^T \hat{\beta}_s^\mathbb{P} (\hat{S}_s^+ a_s^1/2 Z_s^\mathbb{P}) ds - \int_t^T Z_s^\mathbb{P} \cdot dX_s^c \mathbb{P} - \int_t^T dM^\mathbb{P} + \int_t^T dK^\mathbb{P}, \ t \in [0, T], \ \mathbb{P} - a.s.
$$

Moreover, there is some $\mathbb{F}^\mathbb{P}_0$-predictable process $Z$ which aggregates the family $(Z^\mathbb{P})_{\mathbb{P} \in \mathcal{P}_0}$. 24
The same linearization argument that we used in the proof of Lemma A.1 implies that
\[
\hat{y}_t^P = \hat{y}_{t\tau_\epsilon}^P - \int_t^{\tau_\epsilon} \hat{f}_s^P(y_s^P, \alpha_s^{1/2} Z_s^P)ds - \int_t^{\tau_\epsilon} \hat{z}_s^P \cdot \alpha_s^{1/2} dW_s^P - \int_t^{\tau_\epsilon} \hat{m}_s^P + \hat{k}_s^P = 0.
\]

By Theorem 3.1 in [12], this reflected BSDE is wellposed and \( \hat{y}_t^P \) is càdlàg. By abuse of notation, we denote \( \hat{\gamma}^+(\hat{\omega}) := \hat{\gamma}^+(\hat{\pi}(\hat{\omega})) \). We claim that \( \hat{y}_0^P = \hat{\gamma}^+, P \otimes P_0 - a.s. \) Indeed, we argue by contradiction, and assume without loss of generality that \( \hat{y}_0^P > \hat{\gamma}^+ \). For each \( \epsilon > 0 \), denote \( \tau_\epsilon := \inf \{ t : \hat{y}_t^P \leq \hat{\gamma}_t^+ + \epsilon \} \). Then \( \tau_\epsilon \) is an \( \mathbb{F}_+ \)-stopping time and \( \hat{y}_{t\tau_\epsilon}^P \geq \hat{\gamma}_{t\tau_\epsilon}^+ + \epsilon > \hat{\gamma}_{t\tau_\epsilon}^+ \) for all \( t \leq \tau_\epsilon \). Thus \( \hat{k}_{t\tau_\epsilon} = 0, P \otimes P_0 - a.s., \) for \( 0 \leq t \leq \tau_\epsilon \) and thus
\[
\hat{y}_t^P = \hat{y}_{t\tau_\epsilon}^P - \int_t^{\tau_\epsilon} \hat{f}_s^P(y_s^P, \alpha_s^{1/2} Z_s^P)ds - \int_t^{\tau_\epsilon} \hat{z}_s^P \cdot \alpha_s^{1/2} dW_s^P - \int_t^{\tau_\epsilon} \hat{m}_s^P, P \otimes P_0 - a.s.
\]

The same linearization argument that we used in the proof of Lemma A.1 implies that
\[
\hat{y}_0^P \leq \hat{\gamma}_0^+ \otimes P_0(\tau_\epsilon, \hat{\gamma}_\tau_\epsilon^+) + C \mathbb{E}^{\mathbb{P} \otimes P_0} \left[ \hat{y}_{\tau_\epsilon}^P - \hat{\gamma}_{\tau_\epsilon}^+ \right] \leq \hat{\gamma}_0^+(\tau_\epsilon, \hat{\gamma}_\epsilon^+) + C \epsilon,
\]
for some \( C > 0 \). However, by Lemma 3.4, we know that \( \hat{\gamma}_0^+(\tau_\epsilon, \hat{\gamma}_\epsilon^+) \leq \hat{\gamma}_0^+ \), which contradicts the fact that \( \hat{y}_0^P > \hat{\gamma}_0^+ \).

Then, by exactly the same arguments as in Lemma 2.2, we can go from the enlarged space to \( \Omega \) and obtain for some \( (Z^P)_{P \in P_0} \subset \mathbb{H}_0(P^+_0, P), \) and \( (M^P, K^P)_{P \in P_0} \subset \mathbb{M}_0(P^+_0, P) \times \mathbb{P}_0(P^+_0, P) \)
\[
\hat{\gamma}_t^+ = \xi - \int_t^T \hat{f}_s^P(\hat{\gamma}_s^+, \alpha_s^{1/2} Z_s^P)ds - \int_t^T \hat{z}_s^P \cdot \alpha_s^{1/2} dW_s^P - \int_t^T \hat{m}_s^P + \int_t^T dK_s^P, t \in [0, T], \ P - a.s.
\]

Then, by Karandikar [47], since \( \hat{\gamma}^+ \) is a càdlàg semimartingale, we can define a universal process denoted by \( \langle \hat{\gamma}^+, X \rangle \) which coincides with the quadratic co-variation of \( \hat{\gamma}^+ \) and \( X \) under each probability \( P \in P_0 \). In particular, the process \( \langle \hat{\gamma}^+, X \rangle \) is \( P_0 \)-quasi-surely continuous and hence is \( \mathbb{F}^{P_0+} \)-predictable (or equivalently \( \mathbb{F}^{P_0} \)-predictable). Similarly to the proof of Theorem 2.4 of [63], we can then define a universal \( \mathbb{F}^{P_0} \)-predictable process \( Z \) by
\[
Z_t := \hat{\alpha}_t^{\mathbb{P} \otimes P_0 \otimes P_0} \left[ \frac{d(\hat{\gamma}_t^+, X)_t}{dt} \right],
\]
where \( \hat{\alpha}_t^{\mathbb{P} \otimes P_0 \otimes P_0} \) represents the Moore-Penrose pseudoinverse of \( \hat{\alpha}_t \). In particular, \( Z \) aggregates the family \( \{Z^P, P \in P_0\} \). \( \square \)

We end this section with a remark, which explains that in some cases, the path regularization that we used is actually unnecessary, and we can obtain a semi-martingale decomposition for \( \hat{\gamma} \) directly.

**Remark 3.1.** Assume that for any \( (t, \omega) \in [0, T] \times \Omega \), all the probability measures in \( \mathbb{P}(t, \omega) \) satisfy the Blumenthal 0 – 1 law. This would be the case for instance if we where working with the set \( \mathbb{F}_S \) used in [76]. Then, for any \( P \in \mathbb{P}(t, \omega) \), the filtration \( \mathbb{F}^P \) is right-continuous and
therefore satisfies the usual conditions. Recall that we have shown that \( \tilde{Y} \) is càdlàg, and by Lemma 3.5, it verifies
\[
\sup_{\mathbb{P} \in \mathcal{P}_0} \mathbb{E}^\mathbb{P} \left[ \text{ess sup}_{t \in [0,T]} |\tilde{Y}_t|^p \right] < +\infty.
\]
Moreover, by the Blumenthal 0–1 law, (3.1) and (3.2) rewrite
\[
\tilde{Y}_{\sigma(\omega)}(\omega) = \sup_{\mathbb{P} \in \mathcal{P}(\sigma(\omega),\omega)} \mathbb{Y}_{\sigma(\omega)}^p(\tau,\tilde{Y}_\tau) = \sup_{\mathbb{P} \in \mathcal{P}(\sigma(\omega),\omega)} \tilde{Y}_{\sigma(\omega)}^p(\tau,\tilde{Y}_\tau).
\]
Hence, \( \tilde{Y} \) is a \( \mathcal{F}^\mathbb{P} \)–supermartingale in the terminology of [11]. We can then apply Theorem 3.1 of [11] to obtain directly the semi-martingale decomposition of Lemma 3.6. The aggregation of the family \( (Z^\mathbb{P})_{\mathbb{P} \in \mathcal{P}_0} \) can still be done, but requires to use Karandikar’s approach [47], combined with the Itô formula for càdlàg processes of [52][p. 538]. Then, one can also generalize the results on 2BSDEs of the section below. This however requires that in the definition of a 2BSDE (see Definition 4.1), the processes \( Y \) and \( K \) are only càdlàg, instead of càdlàg. With this change, all our results still go through.

4 Application to 2BSDEs

4.1 Definition

We shall consider the following 2BSDE, which verifies
\[
Y_t = \xi - \int_t^T \mathbb{Y}^p_s(Y_s,\tilde{Z}_s^{1/2}Z_s)ds - \left( \int_t^T Z_s \cdot dX_s^\mathbb{P} \right)^p - \int_t^T dM^\mathbb{P}_s + K^\mathbb{P}_T - K^\mathbb{P}_t, \quad 0 \leq t \leq T, \quad \mathcal{P}_0 - q.s.
\]  
(4.1)

**Definition 4.1.** We will say that the quadruple \( (Y,Z,(M^\mathbb{P})_{\mathbb{P} \in \mathcal{P}_0},(K^\mathbb{P})_{\mathbb{P} \in \mathcal{P}_0}) \in \mathbb{D}^p(\mathcal{F}^\mathbb{P}_T) \times \mathbb{M}^p_0(\mathcal{F}^\mathbb{P}_T) \times \mathbb{M}^p_0((\mathcal{F}^\mathbb{P}_T)_{\mathbb{P} \in \mathcal{P}_0}) \) is a solution to the 2BSDE (4.1) if (4.1) holds \( \mathbb{P} \)-q.s. and if the family \( \{K^\mathbb{P}, \mathbb{P} \in \mathcal{P}_0\} \) satisfies the minimality condition
\[
K^\mathbb{P}_t = \text{ess inf}_{\mathbb{P} \in \mathcal{P}_0(t;\mathcal{F}^\mathbb{P}_t)} \mathbb{E}^{\mathbb{P}'} \left[ K^{{\mathbb{P}'}^p}_{\tau} \bigg| \mathcal{F}^{{\mathbb{P}'}^p}_\tau \right], \quad 0 \leq t \leq T, \quad \mathbb{P} \text{– a.s., } \forall \mathbb{P} \in \mathcal{P}_0.
\]  
(4.2)

**Remark 4.1.** If we assume that \( b^p = 0, \mathbb{P} \)-a.s. for any \( \mathbb{P} \in \mathcal{P}_0 \), then we have that \( X^c_{\mathbb{P}} = X, \mathbb{P} \)-a.s. for any \( \mathbb{P} \in \mathcal{P}_0 \). Then, we can use the general result given by Nutz [62] to obtain the existence of a \( \mathcal{P}_0 \)-q.s. càdlàg \( \mathbb{P}^0_+ \)-progressively measurable process, which we denote by \( \int_0^t Z_s \cdot dX_s \), such that
\[
\int_0^T Z_s \cdot dX_s = \left( \int_0^T Z_s \cdot dX_s \right)^\mathbb{P}, \quad \mathbb{P} \text{– a.s.}
\]
Hence, we can then also find an \( \mathbb{P}^0_+ \)-progressively measurable process \( N \) which aggregates the process \( M^\mathbb{P} = K^\mathbb{P} \), and which is therefore a \((\mathbb{P}^\mathbb{P}_+,\mathbb{P})\)-supermartingale for any \( \mathbb{P} \in \mathcal{P}_0 \). However, the Doob-Meyer decomposition of \( N \) into a sum of a martingale and a nondecreasing process generally depends on \( \mathbb{P} \). If furthermore the set \( \mathcal{P}_0 \) only contains elements satisfying the predictable martingale representation property, for instance the set \( \mathcal{F}^\mathbb{P}_T \) used in [76], then we have

\footnote{Notice that this result only holds under some particular set-theoretic axioms. For instance, one can assume the usual ZFC framework, plus the axiom of choice, and either add the continuum hypothesis or Martin’s axiom.}
that \( M^P = 0 \), \( \mathbb{P} - a.s. \), for any \( \mathbb{P} \in \mathcal{P}_0 \), so that the above reasoning allows to aggregate the non-decreasing processes \( K^P \).

We first state the main result of this part

**Theorem 4.1.** Let \( \xi \in \mathbb{L}^P_{B^\infty} \). Under Assumptions 2.1 and 3.1, there exists a unique solution \((Y,Z,(M^P)_{\mathbb{P} \in \mathcal{P}_0},(K^P)_{\mathbb{P} \in \mathcal{P}_0})\) to the 2BSDE (4.1).

### 4.2 Uniqueness and stochastic control representation

We start by proving a representation of a solution to 2BSDEs, which provides incidentally its uniqueness.

**Theorem 4.2.** Let Assumptions 2.1 and 3.1 hold. Let \( \xi \in \mathbb{L}^P_{B^\infty} \) and \((Y,Z,(M^P)_{\mathbb{P} \in \mathcal{P}_0},(K^P)_{\mathbb{P} \in \mathcal{P}_0})\) be a solution to the 2BSDE (4.1). For any \( \mathbb{P} \in \mathcal{P}_0 \), let \((Y^F,Z^F,M^F)\in \mathbb{D}^F(F^+,\mathbb{P})\times \mathbb{H}^F(F^+,\mathbb{P})\times \mathcal{M}^F(F^+,\mathbb{P})\times \mathcal{M}^F(F^+,\mathbb{P})\) be the solutions of the corresponding BSDEs (2.7). Then, for any \( \mathbb{P} \in \mathcal{P}_0 \) and \( 0 \leq t_1 \leq t_2 \leq T \),

\[
Y_{t_2} = \text{ess sup}_{\mathbb{P}' \in \mathcal{P}_0(t_1,\mathbb{P},F^+_t)} Y^F_{t_1}(t_2,Y_{t_2}), \quad \mathbb{P} - a.s. \tag{4.3}
\]

Thus, the 2BSDE (4.1) has at most one solution in \( \mathbb{D}^F(F^+,\mathbb{P})\times \mathbb{H}^F(F^+,\mathbb{P})\times \mathcal{M}^F(F^+,\mathbb{P})\times \mathcal{M}^F(F^+,\mathbb{P})\).

**Proof.** We start by proving the representation (4.3) in three steps.

(i) Fix some \( \mathbb{P} \in \mathcal{P}_0 \) and then some \( \mathbb{P}' \in \mathcal{P}_0(t_1,\mathbb{P},F^+_t) \). Since (4.1) holds \( \mathbb{P}' - a.s. \), we can see \( Y \) as a supersolution of the BSDE on \([t_1,t_2]\), under \( \mathbb{P}' \), with generator \( f_{\mathbb{P}'} \) and terminal condition \( Y_{t_2} \). By the comparison principle of Lemma A.3 (together with Lemma 2.2), we deduce immediately that \( Y_{t_1} \geq Y^F_{t_1}(t_2,Y_{t_2}), \mathbb{P}' - a.s. \). Then, since \( Y^F_{t_1}(t_2,Y_{t_2}) \) (or a \( \mathbb{P} \)-version of it) is \( \mathcal{F}^+_{t_1} \)-measurable and since \( Y_{t_1} \) is \( \mathcal{F}^+_{t_1} \)-measurable, we deduce that the inequality also holds \( \mathbb{P} - a.s. \), by definition of \( \mathcal{P}_0(t_1,\mathbb{P},F^+_t) \) and the fact that measures extends uniquely to completed \( \sigma \)-algebras. We deduce that

\[
Y_{t_1} = \text{ess sup}_{\mathbb{P}' \in \mathcal{P}_0(t_1,\mathbb{P},F^+_t)} Y^F_{t_1}(t_2,Y_{t_2}), \quad \mathbb{P} - a.s.,
\]

by arbitrariness of \( \mathbb{P}' \).

(ii) We now show that

\[
C^F_{t_1} := \text{ess sup}_{\mathbb{P}' \in \mathcal{P}_0(t_1,\mathbb{P},F^+_t)} \mathbb{E}^\mathbb{P}' \left[ \left( K^F_{t_2} - K^F_{t_1} \right)^P \mathcal{F}^+_{t_1} \right] < +\infty, \quad \mathbb{P} - a.s.
\]

First of all, we have by definition

\[
\left( K^F_{t_2} - K^F_{t_1} \right)^P \leq C \left( \sup_{t_1 \leq t \leq t_2} |Y^P_t|^P + \left( \int_{t_1}^{t_2} |f_{\mathbb{P}'} 0 |^P ds \right)^P + \left( \int_{t_1}^{t_2} \|a_1/2 Z_s \|^P ds \right)^P \right)
\]

\[+ C \left( \left( \int_{t_1}^{t_2} Z_s \cdot dX^0_{\mathbb{P}'} \right)^P + \left( \int_{t_1}^{t_2} dM^0_{\mathbb{P}'} \right)^P \right),
\]
so that we obtain by BDG inequalities

$$
\mathbb{E}^P \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] \leq C \left( \phi_P + \| Y \|_{\mathbb{E}^P_0}^p + \| Z \|_{\mathbb{E}^P_0}^p + \sup_{\mathcal{P} \in \mathcal{P}_0} \mathbb{E}^P \left[ [M]^p_{T} \right] \right),
$$

(4.4)

Next, we claim that the family

$$
\left\{ \mathbb{E}^P \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right], \mathbb{P} \in \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+) \right\},
$$

is upward directed.

Indeed, let us consider $(\mathbb{P}^1, \mathbb{P}^2) \in \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+) \times \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+)$, and let us define the following subsets of $\Omega$

$$
A_1 := \left\{ \omega \in \Omega, \mathbb{E}^\mathbb{P}^1 \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] (\omega) > \mathbb{E}^\mathbb{P}^2 \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] (\omega) \right\},
$$

$$
A_2 := \Omega \setminus A_1.
$$

Then, $A_1, A_2 \in \mathcal{F}_{t_1}^+$, and we can define the following probability measure on $(\Omega, \mathcal{F}_T)$

$$
\mathbb{P}^{1,2}(B) := \mathbb{P}^1(A_1 \cap B) + \mathbb{P}^2(A_2 \cap B), \text{ for any } B \in \mathcal{F}_T.
$$

By Assumption 2.1(v), we know that $\mathbb{P}^{1,2} \in \mathcal{P}_0$, and by definition, we further have $\mathbb{P}^{1,2} \in \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+)$ as well as, $\mathbb{P} \sim a.s.$,

$$
\mathbb{E}^{\mathbb{P}^{1,2}} \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] = \mathbb{E}^{\mathbb{P}^1} \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] \vee \mathbb{E}^{\mathbb{P}^2} \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right],
$$

which proves the claim.

Therefore, by classical results for the essential supremum (see e.g. Neveu [61]), there exists a sequence $(\mathbb{P}^n)_{n \geq 0} \subset \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+)$ such that

$$
\text{ess sup}_{\mathbb{P}^n \in \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+)} \mathbb{E}^\mathbb{P}^n \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] = \lim_{n \to \infty} \uparrow \mathbb{E}^\mathbb{P}^n \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right],
$$

Then using (4.4) and the monotone convergence theorem under $\mathbb{P}$, we deduce that

$$
\mathbb{E}^\mathbb{P} \left[ C_{t_1}^p \right] \leq \lim_{n \to \infty} \uparrow \mathbb{E}^\mathbb{P}^n \left[ \left( K_{t_2} - K_{t_1} \right)^p \big| \mathcal{F}_{t_1}^+ \right] \leq C \left( \phi_P + \| Y \|_{\mathbb{E}^P_0}^p + \| Z \|_{\mathbb{E}^P_0}^p + \sup_{\mathcal{P} \in \mathcal{P}_0} \mathbb{E}^\mathbb{P} \left[ [M]^p_{T} \right] \right) < +\infty,
$$

which provides the desired result.

(iii) We now prove the reverse inequality. Since we will use a linearization argument, we work on the enlarged space, remembering that this is without loss of generality by Lemma 2.2. Fix $\mathbb{P}' \in \mathcal{P}_0$. For every $\mathbb{P}' \in \mathbb{P}' \in \mathcal{P}_0(t_1, \mathbb{P}, \mathbb{F}^+)$, we extend the definition of $(Y, Z, (M^P)_{\mathcal{P} \in \mathcal{P}_0}, (K^P)_{\mathcal{P} \in \mathcal{P}_0})$ on $\mathbb{P}$ as in (2.1), and denote

$$
\delta Y := Y - \mathbb{Y}^\mathbb{P}' \otimes \mathbb{P}_0, \delta Z := Z - \mathbb{Z}^\mathbb{P}' \otimes \mathbb{P}_0 \text{ and } \delta M^\mathbb{P}' := M^\mathbb{P}' - \mathbb{M}^\mathbb{P}' \otimes \mathbb{P}_0.
$$

By Assumption 2.1(i), there exist two bounded processes $\lambda^{\mathbb{P}'}$ and $\eta^{\mathbb{P}'}$ such that for all $t_1 \leq t \leq t_2$

$$
\delta Y_t = \int_t^{t_2} \left( \lambda^{\mathbb{P}'}_s \delta Y_s + \eta^{\mathbb{P}'}_s \cdot \mathbb{a}^{1/2}_s \delta Z_s \right) \, ds - \int_t^{t_2} \delta Z_s \cdot \mathbb{a}^{1/2}_s \, dW^\mathbb{P}'_s - \int_t^{t_2} \int_s^{t_2} \delta M^\mathbb{P}'_s \cdot \mathbb{K}^\mathbb{P}'_s, \mathbb{P}' \otimes \mathbb{P}_0-a.s.
$$
Define for $t_1 \leq t \leq t_2$ the following continuous process
\[ \Delta_t^{p'} := \exp \left( \int_{t_1}^{t} \left( \lambda_s^{p'} - \frac{1}{2} \| \eta_s^{p'} \|^2 \right) ds - \int_{t_1}^{t} \eta_s^{p'} \cdot dW_s^{p'} \right), \quad \mathbb{P} \otimes \mathbb{P}_0 - \text{a.s.} \quad (4.5) \]

Note that since $\lambda^{p'}$ and $\eta^{p'}$ are bounded, we have for all $p \geq 1$, for some constant $C_p > 0$, independent of $\mathbb{P}$
\[ \mathbb{E}^{p'} \otimes \mathbb{P}_0 \left[ \sup_{t_1 \leq t \leq t_2} \left( \Delta_t^{p'} \right)^p + \sup_{t_1 \leq t \leq t_2} \left( \Delta_t^{p'} \right)^{-p} \right] \leq C_p, \quad \mathbb{P} \otimes \mathbb{P}_0 - \text{a.s.} \quad (4.6) \]

Then, by Itô’s formula, we obtain
\[ \delta Y_{t_1} = \mathbb{E}^{p'} \otimes \mathbb{P}_0 \left[ \int_{t_1}^{t_2} \Delta_t^{p'} dK_t^{p'} \right], \quad (4.7) \]

because the martingale terms vanish when taking conditional expectation. We therefore deduce
\[ \delta Y_{t_1} \leq \left( \mathbb{E}^{p'} \otimes \mathbb{P}_0 \left[ \sup_{t_1 \leq t \leq t_2} \left| \Delta_t^{p'} \right|^{1 + \frac{1}{p}} \right] \right)^{\frac{1}{p + 1}} \left( \mathbb{E}^{p'} \otimes \mathbb{P}_0 \left[ \left( K_{t_2}^{p'} - K_{t_1}^{p'} \right)^{1 + \frac{1}{p}} \right] \right)^{\frac{1}{p + 1}}. \]

Remember $Y$ and $K^{p'}$ are extended on $\Omega$ as in (2.1), then it only depends on $X$ and not on $B$. Going back now to the canonical space $\Omega$, it follows by Lemma 2.2 that
\[ \delta Y_{t_1} := Y_{t_1} - \tilde{Y}_{t_1}^{p'} \leq C \left( C_{t_1}^{p'} \right)^{1 + \frac{1}{p + 1}} \left( \mathbb{E}^{p'} \left[ K_{t_2}^{p'} - K_{t_1}^{p'} \right] \right)^{\frac{1}{p + 1}}. \]

By arbitrariness of $\mathbb{P}$, we deduce thanks to (4.2) that
\[ Y_{t_1} - \text{ess sup}_{p' \in \mathbb{P}_0(t_1, t_2, \mathcal{F}_t)} Y_{t_1}^{p'}(t_2, Y_{t_2}) \leq 0, \quad \mathbb{P} - \text{a.s.} \]

Finally, the uniqueness of $Y$ is immediate by the representation (4.3). Then, since
\[ [Y, X]_t = \int_0^t \tilde{a}_s Z_s ds, \quad \mathbb{P} - \text{a.s.}, \]

$Z$ is also uniquely defined, $\tilde{a}_tdt \otimes \mathbb{P}_0 - \text{q.s.}$ We therefore deduce that the processes $M^p - K^p$ are also uniquely defined for any $\mathbb{P} \in \mathbb{P}_0$. But, since they are $(\mathbb{F}_t^+, \mathbb{P})$–supermartingales, such that in addition $(K_t^p, M_t^p) \in L_0^\infty(\mathbb{F}_+^p, \mathbb{P}) \times L_0^1(\mathbb{F}_+^p, \mathbb{P})$ for any $t \in [0, T]$, and since $K^p$ is $\mathbb{F}_+^p$–predictable, the uniqueness of $M^p$ and $K^p$ is a simple consequence of the uniqueness in the Doob-Meyer decomposition of these supermartingales. \[ \square \]

4.3 A priori estimates and stability

In this section, we give a priori estimates for 2BSDEs, which, as in the case of the classical BSDEs, play a very important role in the study of associated numerical schemes for instance. The proofs are actually based on the general results given very recently in [12].
**Theorem 4.3.** Let Assumptions 2.1 and 3.1 hold. Let $\xi \in L^{p,\kappa}_{L_0}$ and $(Y, Z, (M^P)_{P \in \mathcal{P}_0}, (K^P)_{P \in \mathcal{P}_0})$ be a solution to the 2BSDE (4.1). Then, there exists a constant $C_\kappa$ depending only on $\kappa$, $T$ and the Lipschitz constant of $f$ such that
\[
\|Y\|_{D^P_0}^p + \|Z\|_{H^P}^p + \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ (K^P)^p \right] + \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ |M^P|^p_T \right] \leq C \left( \|\xi\|_{L^{p,\kappa}_{L_0}}^p + \phi_f^{p,\kappa} \right),
\]

**Proof.** First, by Lemma 3.5, we have for any $P \in \mathcal{P}_0$
\[
Y_t = \underset{P' \in \mathcal{P}_0(t, \mathbb{F}, \mathcal{P}_0)}{\text{ess sup}} \mathcal{Y}^P_t (T, \xi), \quad P - a.s.
\]
Furthermore, by Lemma A.1 (together with Lemma 2.2), we know that there exists a constant $C_\kappa$ depending only on $\kappa$, $T$ and the Lipschitz constant of $f$, such that for all $P$
\[
\left| \mathcal{Y}^P_t (T, \xi) \right| \leq C_\kappa \mathbb{E}^P \left[ |\xi|^\kappa + \int_t^T \left| \mathcal{F}^P_s (T, \xi) \right|^{\kappa} ds \right], \quad P - a.s. \tag{4.8}
\]
Hence, we deduce immediately
\[
\|Y\|_{D^P_0}^p \leq C \left( \|\xi\|_{L^{p,\kappa}_{L_0}}^p + \phi_f^{p,\kappa} \right).
\]
Now, by extending the definition of $(Y, Z, (M^P)_{P \in \mathcal{P}_0}, (K^P)_{P \in \mathcal{P}_0})$ on the enlarged space $\Omega$ (see (2.1)), one has for every $P \in \mathcal{P}_0$,
\[
Y_t = \xi - \int_t^T \mathcal{F}^P_s (Y_s, \mathcal{A}^S_t Z_s) ds - \int_t^T Z_s \cdot \mathcal{A}^S_t dW^P_s - \int_t^T dM^P_s + \int_t^T dK^P_s, \quad P \otimes \mathcal{P}_0 - a.s.
\]
Then for every $P \in \mathcal{P}_0$, $(Y, Z, M^P, K^P)$ can be interpreted as a supersolution of a BSDE in the enlarged space $\Omega$. We can therefore use Theorem 2.1 of [12] (notice that the constants appearing there do not depend on the underlying probability measure) to obtain the required estimates. Noticing once again that the norms of $Z$, $K^P$ and $M^P$ are the same on the enlarged space $\Omega$ or on $\Omega$, it follows then
\[
\|Z\|_{H^P}^p + \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ (K^P)^p \right] + \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ |M^P|^p_T \right] \leq C \left( \|\xi\|_{L^{p,\kappa}_{L_0}}^p + \phi_f^{p,\kappa} \right),
\]
where we used the fact that by definition
\[
\|\xi\|_{L^{p,\kappa}_{L_0}}^p \leq \|\xi\|_{L^{p,\kappa}_{L_0}}^p \text{ and } \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ \int_0^T \left| \mathcal{F}^P_s (0) \right|^p ds \right] \leq \phi_f^{p,\kappa}.
\]

\[]

Next, we also have the following estimates for the difference of two solutions of 2BSDEs, which plays a fundamental role for stability properties.
Theorem 4.4. Let Assumptions 2.1, and let us be given two generators $f^1$ and $f^2$ such that 3.1 holds. Assume that for $i = 1, 2$, $\xi^i \in \mathbb{L}_{0}^{p, \kappa}$ and $(Y^i, Z^i, (M^i,P)_{P \in \mathcal{P}_0}, (K^i,P)_{P \in \mathcal{P}_0})$ is a solution to the 2BSDE with generator $f^i$ and terminal condition $\xi^i$. Define

\[
\phi_{f^1,f^2}^{p,\kappa} := \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ \sup_{0 \leq t \leq T} \left( \int_0^T \left| f^1_s - f^2_s \right| (y^1_s, \hat{a}^{1/2}_s z^1_s) ds \right)^\frac{p}{2} \right] ^{\frac{2}{p}} \mathcal{F}_t^+ \n\]

\[
\psi_{f^1,f^2}^{p,\kappa} := \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ \int_0^T \left| f^1_s - f^2_s \right|^p (y^1_s, \hat{a}^{1/2}_s z^1_s) ds \right]. \n\]

Then, there exists a constant $C_\kappa$ depending only on $\kappa$, $T$ and the Lipschitz constant of $f^1$ and $f^2$ such that

\[
\|Y^1 - Y^2\|_0^p \leq C \left( \|\xi^1 - \xi^2\|_0^{p, \kappa} + \psi_{f^1,f^2}^{p,\kappa} \right) \n\]

\[
\|Z^1 - Z^2\|_0^p \leq \sup_{P \in \mathcal{P}_0} \mathbb{E}^P \left[ |N^1,P - N^2,P|_{T}^{\frac{p}{2}} \right] \leq C \left( \|\xi^1 - \xi^2\|_0^{p, \kappa} + \phi_{f^1,f^2}^{p,\kappa} \right), \n\]

where we have once more defined $N^i,P := M^i,P - K^i,P$ for any $P \in \mathcal{P}_0$, $i = 1, 2$.

Proof. First of all, by Lemma A.1 (together with Lemma 2.2), we know that there exists a constant $C_\kappa$ depending only on $\kappa$, $T$ and the Lipschitz constant of $f$, such that for all $P$

\[
\|y^1_P - y^2_P\|_0^p \leq C_\kappa \mathbb{E}^P \left[ |\xi^1 - \xi^2|^\kappa + \int_0^T \left| f^1_s - f^2_s \right|^\kappa (y^1_s, \hat{a}^{1/2}_s z^1_s) ds \right] \mathcal{F}_t^+, \ P - a.s. \quad (4.9) \n\]

This immediately provides the estimate for $Y^1 - Y^2$ by the representation formula (4.2) and the definition of the norms and of $\phi_{f^1,f^2}^{p,\kappa}$. Next, we argue exactly as in the proof of Theorem 4.3 by working on the enlarged space $\Omega$ and using now Theorem 2.2 of [12] to obtain the required estimates.

\[\square\]

4.4 Existence through dynamic programming

In this section, we will show that $\hat{Y}^+$ defined in Section 2 is indeed a solution to the 2BSDE (4.1), thus completing the proof of Theorem 4.1.

Recall that $\hat{Y}^+$ is defined by (3.5), and one has processes $(Z, (M^P)_{P \in \mathcal{P}_0}, (K^P)_{P \in \mathcal{P}_0}) \in \mathbb{H}^p_0(\mathbb{P}\mathcal{P}_0) \times \mathbb{M}^p_0((\mathbb{P}^F)_{P \in \mathcal{P}_0}) \times \mathbb{M}^p_0((\mathbb{P}^F)_{P \in \mathcal{P}_0})$ given by Lemma 3.6, so that the only thing left for us is to show that the family $(K^P)_{P \in \mathcal{P}_0}$ satisfies the minimality condition (4.2).

We again extend the definition of $(Y, Z, (M^P)_{P \in \mathcal{P}_0}, (K^P)_{P \in \mathcal{P}_0})$ and $\hat{Y}^+, \mathcal{Y}^P(T, \xi)$ on $\Omega$ as in (2.1) (recall also Lemma 2.2). Then by (4.7), denoting $\delta \hat{Y}^+ := \hat{Y}^+ - \mathcal{Y}^P(T, \xi)$, we have for any $t \in [0, T]$, for any $P \in \mathcal{P}_0$ and any $P' \in \mathcal{P}_0(t, P, F^+)$

\[
\delta \hat{Y}^+_t = \mathbb{E}^P \omega_0 \left[ \int_t^T \Delta_s^P dK_s^P \right] \mathcal{F}_t^+, P - a.s., \n\]

\[
\inf_{t \leq s \leq T} \Delta_s^P \left( K_s^P - K_s^{P'} \right) \mathcal{F}_t^+, P - a.s., \n\]

\[31\]
where $\Delta^{p_i}$ is defined in (4.5). We therefore have
\[
\mathbb{E}^{p} \left[ K_{T}^{p_i} - K_{t}^{p_i} \big| \mathcal{F}_{t}^{+} \right] \leq \left( \mathbb{E}^{p} \left[ \inf_{t \leq s \leq T} \Delta^{p_i} \left( K_{T}^{p_i} - K_{t}^{p_i} \right) \big| \mathcal{F}_{t}^{+} \right] \right)^{\frac{1}{2}} \\
\times \left( \mathbb{E}^{p} \left[ \left( K_{T}^{p_i} - K_{t}^{p_i} \right)_{\mathcal{F}_{t}^{+}} \right] \right)^{\frac{1}{2p}} \left( \mathbb{E}^{p} \left[ \left. \inf_{t \leq s \leq T} \Delta^{p_i} \big| \mathcal{F}_{t}^{+} \right] \right)^{\frac{1}{2p}} \\
\leq C \left( C_{t}^{p_i} \right)^{\frac{1}{2p}} \left( \delta \mathcal{Y}_{t}^{+} \right)^{\frac{1}{2}}.
\]

Notice that by definition $K_{T}^{p_i}$ (defined on $\Omega$) only depends on $X$ and not on $B$, so that we can go back to $\Omega$ and obtain
\[
\mathbb{E}^{p} \left[ K_{T}^{p_i} - K_{t}^{p_i} \big| \mathcal{F}_{t}^{+} \right] \leq C \left( C_{t}^{p_i} \right)^{\frac{1}{2p}} \left( \delta \mathcal{Y}_{t}^{+} \right)^{\frac{1}{2}}.
\]

Then the result follows immediately thanks to Lemma 3.5.

**Remark 4.2.** For other classes of 2BSDEs with possibly non-Lipschitz generator, such as, 2BSDEs under a monotonicity condition [71], quadratic 2BSDEs [72], second-order reflected BSDEs [57], if a Doob-Meyer decomposition for the nonlinear supermartingale is available under any probability measure in the set $\mathcal{P}_{0}$, then together with Proposition 2.1, we can generalize the wellposedness result in Theorem 4.1 to these classes of 2BSDEs when there is no regularity condition on the terminal condition and the generator. In particular, all probability measures in the non-dominated set considered in the articles above do satisfy this property.

## 5 Non-linear optional decomposition and superhedging duality

In this section, we show that under an additional assumption on the sets $\mathcal{P}_{0}$, basically stating that it is rich enough, we can give a different definition of second-order BSDEs, which is akin to a non-linear optional decomposition theorem, as initiated by [35, 40, 51] in a dominated model framework, and more recently by [63] for non-dominated models.

### 5.1 Saturated 2BSDEs

We introduce the following definition.

**Definition 5.1.** The set $\mathcal{P}_{0}$ is said to be saturated if, when $\mathbb{P} \in \mathcal{P}_{0}$, we have $\mathbb{Q} \in \mathcal{P}_{0}$ for every probability measure $\mathbb{Q}$ on $(\Omega, \mathcal{F})$ which is equivalent to $\mathbb{P}$ and under which $X$ is local martingale.

We give now an alternative definition for 2BSDEs of the form
\[
Y_{t} = \xi - \int_{t}^{T} f_{s}^{p}(Y_{s}, \tilde{a}_{s}^{1/2}Z_{s}) ds - \left( \int_{t}^{T} Z_{s} \cdot \tilde{a}_{s}^{1/2} dX_{s}^{c,p} \right)^{p} + K_{T}^{p} - K_{t}^{p}, \quad 0 \leq t \leq T, \quad \mathcal{P}_{0} - q.s. \quad (5.1)
\]

**Definition 5.2.** We will say that the triple $(Y, Z, (\mathbb{K}_{p})_{\mathbb{P} \in \mathcal{P}_{0}}) \in \mathbb{D}^{p}(\mathbb{P}^{U, \mathcal{P}_{0}}) \times \mathbb{H}^{p}(\mathbb{P}^{U, \mathcal{P}_{0}}) \times \prod^{p}(\mathbb{P}^{U, \mathcal{P}_{0}})$ is a saturated solution to 2BSDE (5.1) if (5.1) holds $\mathcal{P}_{0} - q.s.$ and if the family $\{\mathbb{K}_{p}, \mathbb{P} \in \mathcal{P}_{0}\}$ satisfies the minimality condition (4.2).
Remark 5.1. In the above definition, two changes have occurred. First, the orthogonal martingales $M^P$ have disappeared, and the non-decreasing processes $K^P$ are assumed to be $\mathbb{F}_+^P$-optional instead of predictable.

We then have the following result.

Theorem 5.1. Let Assumption 2.1 hold and assume in addition that the set $\mathcal{P}_0$ is saturated. Then there is a unique saturated solution of the 2BSDE (5.1).

Proof. By Theorem 4.1, we know that the following 2BSDE is wellposed

$$Y_t = \xi - \int_t^T \tilde{\rho}^p_s(Y_s, \tilde{\alpha}_s^{1/2}Z_s)ds - \left( \int_t^T Z_s \cdot dX^c_s \right)^p + \int_t^T dM^p_s + K^p_T - K^p_t, \ 0 \leq t \leq T, \ \mathcal{P}_0 - a.s.$$ 

In particular, this means that the process

$$Y_t = \int_t^T \tilde{\rho}^p_s(Y_s, \tilde{\alpha}_s^{1/2}Z_s)ds,$$

is a $(\mathbb{P}_+^P, \mathbb{F})$-supermartingale in $\mathbb{D}_0^p(\mathbb{F}_+^P, \mathbb{P})$ for every $\mathbb{P} \in \mathcal{P}_0$. Since $\mathcal{P}_0$ is saturated, it follows by Theorem 1 of [40] (see also Theorem 3.1 of [41]), that there exists a $\mathbb{F}$-predictable process $\tilde{Z}^P$ such that

$$Y_t = \int_t^T \tilde{\rho}^p_s(Y_s, \tilde{\alpha}_s^{1/2}Z_s)ds - \int_t^T \tilde{Z}^p_s \cdot dX^c_s^p \text{ is non-increasing, } \mathbb{P} - a.s., \text{ for every } \mathbb{P} \in \mathcal{P}_0.$$ 

Hence, we can write

$$Y_t = \xi - \int_t^T \tilde{\rho}^p_s(Y_s, \tilde{\alpha}_s^{1/2}Z_s)ds - \left( \int_t^T \tilde{Z}^p_s \cdot dX^c_s^p \right)^p + \tilde{K}^p_T - \tilde{K}^p_t, \ 0 \leq t \leq T, \ \mathcal{P}_0 - a.s.,$$

where for any $\mathbb{P} \in \mathcal{P}_0$, $\tilde{K}^p$ is càdlàg, non-decreasing $\mathbb{P} - a.s.$ and $\mathbb{F}_+^P$-optional. Moreover, by identification of the martingale parts, we deduce that we necessarily have $\tilde{Z}^p = Z, \tilde{\alpha} dt \times \mathcal{P}_0 - q.s.$

Finally, following the same arguments as in the proof of Theorem 4.3, we deduce that $(\tilde{K}^p)_{\mathbb{P} \in \mathcal{P}_0} \in \mathbb{D}^{p,p}(\mathbb{F}_+^P)_{\mathbb{P} \in \mathcal{P}_0}$, which ends the proof. \hfill $\Box$

5.2 A superhedging duality in uncertain, incomplete and non-linear markets

The result of the previous section finds an immediate application to the so-called problem of robust superhedging. Before discussing the related results in the literature, let us explain exactly what the problem is.

We consider a standard financial market (possibly incomplete) consisting of a non-risky asset and $n$ risky assets whose dynamics are uncertain. Concretely, let $U$ be some (nonempty) Polish space, $\mathcal{U}$ denote the collection of all $U$-valued $\mathbb{F}$-progressively measurable processes, $(\mu, \sigma) : [0, T] \times \Omega \times U \to \mathbb{R}^d \times \mathbb{S}^d$ be the drift and volatility coefficient function such that for some constant $L > 0$,

$$| (\mu, \sigma)(t, \omega, u) - (\mu, \sigma)(t', \omega', u) | \leq L(\sqrt{|t - t'|} + |\omega_{t\wedge} - \omega'_{t'\wedge}|).$$

Then the dynamics of risky assets are given by

$$X^{t,\omega,\nu}_s = \omega_t + \int_t^s \mu(r, X^{t,\omega,\nu}_r, \nu_r)dr + \int_t^s \sigma(r, X^{t,\omega,\nu}_r, \nu_r) dX_r, \ s \in [t, T], \ \mathbb{P}_0 - a.s.,$$

33
with initial condition $X^t_{s,\omega,\nu} = \omega_s$ for $s \in [0, t]$.

Then, we define for every $(t, \omega) \in [0, T] \times \Omega$

$$U^t(t, \omega) := \{ \mathbb{P}_0 \circ (X^t_{s,\omega,\nu})^{-1} : \nu \in \mathcal{U} \}.$$ 

It is known (see Theorem 3.1 and Lemma 3.4 in [38] or Theorem 2.4 and Proposition 2.2 in [59] in a simpler context) that these sets do satisfy Assumption 2.1. We assume in addition that $U^t_0$ is saturated.

A portfolio strategy is then defined as a $\mathbb{R}^n$-valued and $\mathbb{F}^U_0$-predictable process $(Z_t)_{t \in [0, T]}$, such that $Z^i_t$ describes the number of units of asset $i$ in the portfolio of the investor at time $t$. It is well-known that under some constrained cases, the wealth $Y^{y_0, Z}$ associated to the strategy $Z$ and initial capital $y_0 \in \mathbb{R}$ can be written as

$$Y^{y_0, Z}_t := y_0 + \int_0^t \mathbb{F}_s^{-1}(Y^{y_0, Z}_s, \hat{a}^{1/2}_s Z_s)ds + \int_0^t Z_s \cdot \hat{a}^{1/2}_s dX^P_s, \quad t \in [0, T], \quad \mathbb{P} - a.s., \quad \text{for every } \mathbb{P} \in U^t_0.$$ 

For instance, the classical case corresponds to

$$\mathbb{F}_s^{-1}(y, z) = r s y + z \cdot \theta_s^P,$$ (5.2)

where $r_s$ is the risk-free rate of the market and $\theta^P_s$ is the risk premium vector under $\mathbb{P}$, defined by $\theta^P_s := (\hat{a}^{1/2}_s) \odot (\hat{P}_s - r_s \mathbf{1}_n)$, where $(\hat{a}^{1/2}_s) \odot$ denotes the Moore-Penrose generalized inverse of $\hat{a}^{1/2}_s$.

The simplest example of a non-linear $\mathbb{F}_s^P$ corresponds to the case where there are different lending and borrowing rates $r_s \leq \bar{r}_s$, in which (see Example 1.1 in [36])

$$\mathbb{F}_s^P(y, z) = \bar{r}_s y + z \cdot \hat{\theta}_s^P - (\bar{r}_s - r_s)(y - z \cdot \mathbf{1}_n).$$

We will always assume that $\mathbb{F}_s^P$ satisfies our standing hypotheses in Assumptions 2.1 and 3.1.

Let us now be given some Borel random variable $\xi \in \mathcal{L}(\mathbb{F}^U_0)$. The problem of superhedging $\xi$ corresponds to finding its super-replication price, defined as

$$P_{sup}(\xi) := \inf \{ y_0 \in \mathbb{R}, \exists Z \in \mathcal{H}, \quad Y^{y_0, Z}_T \geq \xi, \quad U^t_0 - q.s. \},$$

where the set of admissible trading strategies $\mathcal{H}$ is defined as the set of $\mathbb{F}^U_0$-predictable processes $Z$ such that in addition, $(Y^{y_0, Z}_t)_{t \in [0, T]}$ is an $\mathbb{F}^P_0$-supermartingale under $\mathbb{P}$ for any $\mathbb{P} \in U^t_0$, that is for any $0 \leq s \leq t \leq T$

$$Y^{y_0, Z}_{s,\omega,\nu} \geq Y^P_{s,\omega,\nu}(t, Y^{y_0, Z}_t), \quad \mathbb{P} - a.s.$$ 

In the case where $\mathbb{F}_s^P$ corresponds to our first example (5.2) with $r = 0$, and where the set of measures considered satisfy the predictable martingale representation property (that is the financial market is complete under any of the measures considered) this superhedging price has been thoroughly studied in the recent literature, see among others [2, 6, 25, 26, 59, 64, 66, 70, 73, 77, 78, 79]. The extension to possibly incomplete markets has been carried out notably by [10] in discrete-time and more recently by [63] in continuous time for models possibly incorporating jumps. Our result below extends all the results for continuous processes to markets with non-linear portfolio dynamics. Of course, the same proof would go through for the more general jump case, provided that a 2BSDE theory, extending that of [48, 49], is obtained in such a setting.
Theorem 5.2. Let \((Y, Z)\) be the first two components of the saturated solution of the 2BSDE with generator \(\hat{f}^P\) and terminal condition \(\xi\). Then
\[
P_{\sup}(\xi) = \sup_{P \in \mathcal{P}_0^U} \mathbb{E}^P [Y_0],
\]
and \(Z \in \mathcal{H}\) is a superhedging strategy for \(\xi\).

**Proof.** First of all, assume that we have some \(Z \in \mathcal{H}\) such that \(Y_{T_0}^{y_0, Z} \geq \xi, \mathcal{P}_0^U - \text{q.s.}\). Then, since \(Y_{T_0}^{y_0, Z}\) is an \(\mathcal{E}^P\)–supermartingale under \(P\) for any \(P \in \mathcal{P}_0^U\), we have
\[
y_0 \geq \mathcal{Y}_0^P(T, Y_{T_0}^{y_0, Z}), \mathcal{P}_0^U - \text{q.s.}
\]
However, by the comparison result of Lemma A.3 (together with Lemma 2.2), we also have \(\mathcal{Y}_0^P(T, Y_{T_0}^{y_0, Z}) \geq \mathcal{Y}_0^P(T, \xi)\), from which we deduce
\[
y_0 \geq \mathcal{Y}_0^P(T, \xi), P - \text{a.s.}
\]
In particular, for any \(P \in \mathcal{P}_0^U\), we deduce that
\[
y_0 \geq \esssup_{P' \in \mathcal{P}_0^U(0, P, \mathbb{F}^+)} \mathcal{Y}_0^P(T, \xi) = Y_0, P - \text{a.s.,}
\]
where we have used Lemma 3.5. It therefore directly implies, since \(y_0\) is deterministic, that
\[
y_0 \geq \sup_{P \in \mathcal{P}_0^U} \mathbb{E}^P [Y_0].
\]

For the reverse inequality, let \((Y, Z, (K^P)_{P \in \mathcal{P}_0^U}) \in \mathcal{D}^P(\mathbb{R}^{U_+}, \mathbb{P}^U) \times \mathbb{H}^P(\mathbb{R}^{U, \mathcal{P}_0^U}) \times \mathbb{P}^P(\mathbb{F}_+^U, P \in \mathcal{P}_0^U)\) be the unique saturated solution to the 2BSDE with generator \(\hat{f}^P\) and terminal condition \(\xi\). Then, we have for any \(P \in \mathcal{P}_0^U\)
\[
Y_0 + \int_0^T \hat{f}_s^P (Y_s, \hat{a}_s^{1/2} Z_s) ds + \int_0^T Z_s \cdot \hat{a}_s^{1/2} dX_{c,s}^c,P = \xi + K^P_T - K^P_t \geq \xi, \mathbb{P} - \text{a.s.}
\]
However, since \(Y_0\) is only \(\mathcal{F}_0^{P_0^U+}\)–measurable, it is not, in general, deterministic, so that we cannot conclude directly. Let us nonetheless consider, for any \(P \in \mathcal{P}_0^U\), \(y^P_0\) the smallest constant which dominates \(Y_0\), \(P - \text{a.s.}\). We therefore want to show that for any \(P \in \mathcal{P}_0^U\)
\[
y^P_0 \leq \sup_{P \in \mathcal{P}_0^U} \mathbb{E}^P [Y_0],
\]
which can be done by following exactly the same arguments as in the proof of Theorem 3.2 in [63]. Finally, we do have \(Z \in \mathcal{H}\), since by Lemma 3.4, \(Y\) is automatically an \(\mathcal{E}^P\)–supermartingale for every \(P \in \mathcal{P}_0^U\). \(\square\)

6 Path-dependent PDEs

In the context of stochastic control theory, using the dynamic programming principle, we can characterize the value function as a viscosity solution of PPDE. Recall that \(\mu, \sigma, U\) as well as \(U\) are the same given in Section 5.2, we introduce a path-dependent PDE
\[
\partial_t v(t, \omega) + G(t, \omega, v(t, \omega), \partial_\omega v, \partial^2_{\omega, \omega} v) = 0, \quad (6.1)
\]
In this Appendix, we collect several results related to BSDE theory which are used throughout the paper. We fix \( r \in [0,T] \) and some \( \mathbb{P} \in \mathcal{P}(r,\omega) \). A generator will here be a map \( g : \):
our results, we will actually need to work on the enlarged canonical space \( \bar{\Omega} \), but we remind the reader that by Lemma 2.2, it is purely a technical tool. Let terminal condition \( g \) and terminal condition \( \xi \) of (A.1) be a supersolution of the BSDE with generator \( g \) and terminal condition \( \xi \) if

\[
y_t = \xi - \int_t^T g_s(y_s, \alpha_s^{1/2} z_s) ds - \int_t^T z_s \cdot \alpha_s^{1/2} dW_s^F - \int_t^T dm_s, \quad t \in [r, T], \quad \mathbb{P} - a.s. \quad (A.1)
\]

Similarly, if we are given a process \( k \in L^p(F_T^+, \mathbb{P}) \), we call \((y, z, m, k)\) a supersolution of the BSDE with generator \( g \) and terminal condition \( \xi \) if

\[
y_t = \xi - \int_t^T g_s(y_s, \alpha_s^{1/2} z_s) ds - \int_t^T z_s \cdot \alpha_s^{1/2} dW_s^F - \int_t^T dm_s + \int_t^T dk_s, \quad t \in [r, T], \quad \mathbb{P} - a.s. \quad (A.2)
\]

A.1 Technical results for BSDEs

Lemma A.1 (Estimates and stability). Let Assumption 2.1 hold. Then, for \( i = 1, 2 \), let us denote by \((y^i, z^i, m^i)\) the solution of the BSDE (A.1) with generator \( g^i \) and terminal condition \( \xi^i \). Then, for any \( \kappa \in (1, p] \), there exists some constant \( C > 0 \) such that

\[
|y_t^i| \leq C\mathbb{E}^F \left[ |\xi_t^i|^\kappa + \int_r^T |g_s^i(0,0)|^\kappa ds \right]^\frac{1}{\kappa}, \quad t \in [r, T], \quad \mathbb{P} - a.s.,
\]

and

\[
\|z\|^p_{H^p(\mathbb{P})} + \|m\|^p_{M^p(\mathbb{P})} \leq C \left( \|\xi\|^p_{L^p(\mathbb{P})} + \mathbb{E}^F \left[ \int_r^T |g_s^i(0,0)|^p ds \right] \right).
\]

Denoting \( \delta \xi : = \xi_1^i - \xi_2^i \), \( \delta y : = y_1^i - y_2^i \), \( \delta z : = z_1^i - z_2^i \), \( \delta m : = m_1^i - m_2^i \), \( \delta g : = (g^1 - g^2)(\cdot, y_1^i, z_1^i) \), we also have

\[
|\delta y_t| \leq C\mathbb{E}^F \left[ |\delta \xi_t|^\kappa + \int_r^T |\delta g_s|^\kappa ds \right]^\frac{1}{\kappa}, \quad t \in [r, T], \quad \mathbb{P} - a.s.,
\]

and

\[
\|\delta z\|^p_{H^p(\mathbb{P})} + \|\delta m\|^p_{M^p(\mathbb{P})} \leq C \left( \|\delta \xi\|^p_{L^p(\mathbb{P})} + \mathbb{E}^F \left[ \int_r^T |\delta g_s|^p ds \right] \right).
\]

Proof. See Section 4 of [12]. \( \square \)

Lemma A.2. For any \( F \)-stopping times \( 0 \leq r \leq \rho \leq \tau \leq T \), any decreasing sequence of \( F \)-stopping times \( (\tau_n)_{n \geq 1} \) converging \( \mathbb{P} \)-a.s. to \( \tau \), and any \( F^+ \)-progressively measurable and right-continuous process \( V \in D^p(F_T^+, \mathbb{P}) \), if \( y(\cdot, V) \) denotes the first component of the solution to the BSDE (A.1) on \([r, \cdot]\) with terminal condition \( V \) and some generator \( g \), we have

\[
\mathbb{E}^F \left[ |y_\rho(\tau, V_\tau) - y_\rho(\tau_n, V_{\tau_n})| \right] \rightarrow_{n \rightarrow \infty} 0.
\]

37
Proof. First of all, by Lemma (2.7), we have
\[ y_p(\tau, V_\tau) - y_p(\tau_n, V_{\tau_n}) = y_p(\tau, V V_\tau) - y_p(\tau, y_\tau(\tau_n, V_{\tau_n})). \]

By Lemma A.1, we therefore have for any \( \kappa \in (1, p] \)
\[ E^F [ |y_p(\tau, V_\tau) - y_p(\tau, y_\tau(\tau_n, V_{\tau_n})) |] \leq C E^F [ |V_\tau - y_\tau(\tau_n, V_{\tau_n}) |^\kappa]. \]

Next, again by a linearization argument, we can find bounded processes \( \lambda \) and \( \eta \) which are \( F \)-progressively measurable such that
\[ y_\tau(\tau_n, V_{\tau_n}) = E^{P \otimes F_0} \left[ \mathcal{E} \left( \int_{\tau_n}^{\tau} \eta_s \cdot dW^P_s \right) e^{\int_{\tau_n}^{\tau} \lambda_s ds} V_{\tau_n} - \int_{\tau}^{\tau_n} e^{\int_{s}^{\tau} \lambda_u du} g_s(0, 0) ds \right] |F_{\tau_n}^+]. \]

Hence, choosing \( \kappa < \tilde{p} < p \)
\[ E^{P \otimes F_0} [ |y_p(\tau, V_\tau) - y_p(\tau, y_\tau(\tau_n, V_{\tau_n})) |] \leq C E^{P \otimes F_0} \left[ \mathcal{E} \left( \int_{\tau_n}^{\tau} \eta_s \cdot dW^P_s \right) e^{\int_{\tau_n}^{\tau} \lambda_s ds} |V_{\tau_n} - V_\tau|^\kappa \right] + C E^{P \otimes F_0} \left[ 1 - E \left( \int_{\tau_n}^{\tau} \eta_s \cdot dW^P_s \right) e^{\int_{\tau_n}^{\tau} \lambda_s ds} |V_\tau|^\kappa \right] \]
\[ + C E^{P \otimes F_0} \left[ \mathcal{E} \left( \int_{\tau_n}^{\tau} \eta_s \cdot dW^P_s \right) \right] e^{\int_{\tau_n}^{\tau} \lambda_s ds} |g_s(0, 0)|^\kappa ds \]
\[ \leq C \left( E^{P \otimes F_0} [ |V_{\tau_n} - V_\tau |^{\tilde{p}}] \right)^{\frac{\tilde{p}}{p}} + C \left( E^{P \otimes F_0} \left[ \left( \int_{\tau_n}^{\tau} \eta_s \cdot dW^P_s \right) e^{\int_{\tau_n}^{\tau} \lambda_s ds} \right]^{\frac{\tilde{p}}{p}} \right)^{\frac{p}{\tilde{p} - p}} \]
\[ + C E^{P \otimes F_0} \left[ \int_{\tau_n}^{\tau} e^{\int_{s}^{\tau} \lambda_u du} |g_s(0, 0)|^{\tilde{p}} ds \right], \]
where we have used Hölder inequality, that \( \lambda \) is bounded and the fact that since \( \eta \) is also bounded, the Doléans-Dade exponential appearing above has finite moments of any order. Now the terms inside the expectations on the right-hand side all converge in probability to 0 and are clearly uniformly integrable by de la Vallée-Poussin criterion since \( V \in D^\infty_p (P^+, \mathbb{P}) \) and \( \tilde{p} < p \).

We can therefore conclude by dominated convergence.

Lemma A.3 (Comparison). Let Assumption 2.1 hold. Then, for \( i = 1, 2 \), let us denote by \((y^i, z^i, m^i, k^i)\) the supersolution of the BSDE (A.2) with generator \( g^i \) and terminal condition \( \xi^i \).
If it holds \( \mathbb{P} - a.s. \) that
\[ \xi_1 \geq \xi_2, \ k^1 - k^2 \text{ is non-decreasing and } g^1(s, y^1_s, z^1_s) \geq g^2(s, y^1_s, z^1_s), \]
then we have for all \( t \in [0, T] \)
\[ y^1_t \geq y^2_t, \ \mathbb{P} - a.s. \]

Proof. We remind the reader that since \( W^\mathbb{P} \) and \( m^i, i = 1, 2 \) are orthogonal and since \( W^\mathbb{P} \) is actually continuous, we not only have \([W^\mathbb{P}, m^i] = 0, \ \mathbb{P} - a.s. \), but also
\[ \langle W^\mathbb{P}, m^i \rangle = \langle W^\mathbb{P}, m^{i,c}^\mathbb{P} \rangle = \langle W^\mathbb{P}, m^{i,d}^\mathbb{P} \rangle = 0, \ \mathbb{P} - a.s., \]
where \( m^{i,c} \mathbb{P} \) (resp. \( m^{i,d} \mathbb{P} \)) is the continuous (resp. purely discontinuous) martingale part of \( m^i \), under the measure \( \mathbb{P} \).
Then, since the $g^j$ are uniformly Lipschitz, there exist two processes $\lambda$ and $\eta$ which are bounded, $\mathbb{F}-a.s.$, and which are respectively $\mathbb{F}_+-$progressively measurable and $\mathbb{F}-$predictable, such that

$$g^2(s, y^1_s, z^1_s) - g^2(s, y^2_s, z^2_s) = \lambda_t (y^1_s - y^2_s) + \eta_s (z^1_s - z^2_s) , \; ds \times d\mathbb{P} - a.e.$$ 

For any $0 \leq t \leq s \leq T$, let us define the following continuous, positive and $\mathbb{F}_+-$progressively measurable process

$$A_{t,s} := \exp \left( \int_t^s \lambda_u du - \int_t^s \eta_u \cdot dW^\mathbb{P}_u - \frac{1}{2} \int_t^s \|\eta_u\|^2 du \right).$$

By Itô’s formula, we deduce classically that

$$y^1_t - y^2_t = \mathbb{E}^{\mathbb{P}} \left[ A_{t,T}(\xi^1 - \xi^2) + \int_t^T A_{t,s} \left[ (g^1 - g^2)(s, y^1_s, z^1_s) ds + d(k^1_s - k^2_s) \right] d\mathbb{F}^+_t \right],$$

from which we deduce immediately that $y^1_t \geq y^2_t$, $\mathbb{P} - a.s.$
