ENumerating Independent Vertex Sets in Grid Graphs

Seungsang Oh and Sangyop Lee

Abstract. A set of vertices in a graph is called independent if no two vertices of the set are connected by an edge. In this paper we use the state matrix recursion algorithm, developed by Oh, to enumerate independent vertex sets in a grid graph and even further to provide the generating function with respect to the number of vertices. We also enumerate bipartite independent vertex sets in a grid graph. The asymptotic behavior of their growth rates is presented.

1. Introduction

The Merrifield–Simmons index and the Hosoya index of a graph, respectively introduced by Merrifield and Simmons [11, 12, 13] and by Hosoya [8], are two prominent examples of topological indices for the study of the relation between molecular structure and physical/chemical properties of certain hydrocarbon compound, such as the correlation with boiling points [5]. An independent set of vertices/edges of a graph $G$ is a set of which no two vertices of the set are connected by a single edge. The Merrifield–Simmons index is defined as the total number, denoted by $\sigma(G)$, of independent vertex sets, while the Hosoya index is defined as the total number of independent edge sets. Especially, finding the Merrifield–Simmons index of graphs is known as the Hard Square Problem in lattice statistics.

One of important problems is to determine the extremal graphs with respect to these two indices within certain prescribed classes. For example, among trees with the same number of vertices, Prodinger and Tichy [17] proved that the star maximizes the Merrifield–Simmons index, while the path minimizes it. The situation for the Hosoya index is absolutely opposite; the star minimizes the Hosoya index, while the path maximizes it [5]. A good summary of results for extremal graphs of various types can be found in a survey paper [18]. The interested reader is referred, however, to other articles [1, 2, 6, 20, 21, 22] that treat several classes of graphs such as fullerene graphs, trees with prescribed degree sequence, graphs with connectivity at most $k$ and the generalized Aztec diamonds.

We also consider a bipartite vertex set $V$ in a graph $G$ in which some vertices of $V$ are colored black and the others are white. We say that $V$ is a bipartite independent vertex set if the vertices of the same color are
independent (vertices with different colors may not be independent). The total number of bipartite independent vertex sets in \( G \) will be called the bipartite Merrifield–Simmons index and denoted by \( \beta(G) \). See the drawings in Figure 1 for examples.

![Figure 1. Independent and bipartite independent vertex sets](image)

Recently several important enumeration problems on two-dimensional square lattice models have been solved by means of the state matrix recursion algorithm, developed by Oh in [14]. This algorithm provides recursive matrix-relations to enumerate monomer and dimer coverings [14], multiple self-avoiding walks and polygons [15], and knot mosaics in quantum knot mosaic theory [16]. Furthermore, these recursive formulae also produce their generating functions. Based upon these results, this algorithm shows considerable promise for further two-dimensional lattice model enumerations.

In this paper we use the state matrix recursion algorithm to calculate the Merrifield–Simmons index of the \( m \times n \) grid graph \( G_{m \times n} \) and further its bipartite Merrifield–Simmons index. Consider the generating function of independent vertex sets (IVSs) with variable \( z \) in \( G_{m \times n} \) defined by

\[
P_{m \times n}(z) = \sum_k k(d) z^d,
\]

where \( k(d) \) is the number of IVSs consisting of \( d \) vertices. Similarly consider the generating function for bipartite independent vertex sets (BIVSs) with variables \( x \) and \( y \) defined by

\[
Q_{m \times n}(x, y) = \sum k(c, d) x^c y^d,
\]

where \( k(c, d) \) is the number of BIVSs consisting of \( c \) white vertices and \( d \) black vertices. We easily notice that \( P_{m \times n}(z) = Q_{m \times n}(z, 0) \). These indices of \( G_{m \times n} \) are then simply obtained by

\[
\sigma(G_{m \times n}) = P_{m \times n}(1) \quad \text{and} \quad \beta(G_{m \times n}) = Q_{m \times n}(1, 1).
\]

Hereafter \( \mathcal{O}_k \) and \( \mathcal{O}'_k \) denote the square zero-matrices of dimensions \( 2^k \) and \( 3^k \), respectively.

**Theorem 1.** The generating function for independent vertex sets is

\[
P_{m \times n}(z) = \text{entry sum of the first column of } (A_m)^n
\]

\[
= (1, 1)\text{-entry of } (A_m)^{n+1},
\]
where $A_m$ is a $2^m \times 2^m$ matrix recursively defined by

$$A_{k+1} = \begin{bmatrix} A_k & B_k \\ zC_k & O_k \end{bmatrix}, \quad B_{k+1} = \begin{bmatrix} A_k & O_k \\ zC_k & O_k \end{bmatrix}$$

and $C_{k+1} = \begin{bmatrix} A_k & B_k \\ O_k & O_k \end{bmatrix}$,

for $k = 0, \ldots, m-1$, with seed matrices $A_0 = B_0 = C_0 = [1]$.

**Theorem 2.** The generating function for bipartite independent vertex sets is

$$Q_{m \times n}(x, y) = \text{entry sum of the first column of } (A_m)^n$$

$$= (1, 1)\text{-entry of } (A_m)^{n+1},$$

where $A_m$ is a $3^m \times 3^m$ matrix defined by

$$A_{k+1} = \begin{bmatrix} A_k & B_k & C_k \\ xD_k & O_k & xE_k \\ yF_k & yG_k & O_k \end{bmatrix},$$

$$B_{k+1} = \begin{bmatrix} A_k & O_k & C_k \\ xD_k & O_k & xE_k \\ yF_k & O_k & O_k \end{bmatrix}, \quad C_{k+1} = \begin{bmatrix} A_k & B_k & O_k \\ xD_k & O_k & O_k \\ yF_k & yG_k & O_k \end{bmatrix},$$

$$D_{k+1} = \begin{bmatrix} A_k & B_k & C_k \\ O_k & O_k & O_k \\ yF_k & yG_k & O_k \end{bmatrix}, \quad E_{k+1} = \begin{bmatrix} A_k & B_k & O_k \\ O_k & O_k & O_k \\ yF_k & yG_k & O_k \end{bmatrix},$$

$$F_{k+1} = \begin{bmatrix} A_k & B_k & C_k \\ xD_k & O_k & xE_k \\ O_k & O_k & O_k \end{bmatrix} \quad \text{and } G_{k+1} = \begin{bmatrix} A_k & O_k & C_k \\ xD_k & O_k & xE_k \\ O_k & O_k & O_k \end{bmatrix},$$

for $k = 0, \ldots, m-1$, with seed matrices $A_0 = \cdots = G_0 = [1]$.

As listed in Table 1, $\sigma(G_{m \times n})$, for $m = n$, is known as the two-dimensional Fibonacci number in virtue of Prodinger and Tichy’s use of the Fibonacci number of graphs [17]. Since this sequence grows in a quadratic exponential rate, we may consider the limits

$$\lim_{m, n \to \infty} (\sigma(G_{m \times n}))^{\frac{1}{mn}} = \eta \quad \text{and} \quad \lim_{m, n \to \infty} (\beta(G_{m \times n}))^{\frac{1}{mn}} = \kappa,$$

which are called the hard square constant and the bipartite hard square constant, respectively. The existence of the hard square constant was shown in [4] [19], and the most updated estimate

$$\eta \approx 1.5030480824753322643220663294755536893857810$$

appeared in [3]. A two-dimensional application of the Fekete’s lemma gives another simple proof of the existence and mathematical lower and upper bounds for these constants.

**Theorem 3.** The double limits $\eta$ and $\kappa$ exist. More precisely, for any positive integers $m$ and $n$,

$$(\sigma(G_{m \times n}))^{\frac{1}{(m+1)(n+1)}} \leq \eta \leq (\sigma(G_{m \times n}))^{\frac{1}{mn}},$$

$$(\beta(G_{m \times n}))^{\frac{1}{(m+1)(n+1)}} \leq \kappa \leq (\beta(G_{m \times n}))^{\frac{1}{mn}}.$$
Here we obtain $2.003942\cdots \leq \kappa \leq 2.181636\cdots$ by letting $m = 9$ and $n = 100$, computed by Matlab.

We adjust the main scheme of the state matrix recursion algorithm introduced in [14] to prove Theorem 1 in Sections 2∼4.

2. Stage 1: Conversion to IVS mosaics

This stage is dedicated to the installation of the mosaic system for IVSs on the grid graph. Lomonaco and Kauffman [9, 10] invented a mosaic system to give a precise and workable definition of quantum knots representing an actual physical quantum system. Oh et al. have developed a state matrix argument for the knot mosaic enumeration in the papers [7, 16].

This argument has been developed further into the state matrix recursion algorithm by which we enumerate monomer–dimer coverings on the square lattice [14]. We follow the notion and terminology in [14] with modification to IVSs. In this paper, we consider the three mosaic tiles $T_1$, $T_2$ and $T_3$ illustrated in Figure 2. Their horizontal and vertical side edges are labeled with two numbers 0, 1 and three letters a, b, c, respectively.

For positive integers $m$ and $n$, an $m \times n$–mosaic is an $m \times n$ rectangular array $M = (M_{ij})$ of those tiles, where $M_{ij}$ denotes the mosaic tile placed at the $i$-th column from ‘left’ to ‘right’ and the $j$-th row from ‘bottom’ to
‘top’. We are exclusively interested in mosaics whose tiles match each other properly to represent IVSs. For this purpose we consider the following rules.

**Horizontal adjacency rule:** Abutting edges of adjacent mosaic tiles in a row are not labeled with any of the following pairs of letters: b/b, c/c.

**Vertical adjacency rule:** Abutting edges of adjacent mosaic tiles in a column must be labeled with the same number.

**Boundary state requirement:** All top boundary edges in a mosaic are labeled with number 0. (See Figure 3)

As illustrated in Figure 3, every IVS in $G_{m \times n}$ can be converted into an $m \times n$–mosaic which satisfies the three rules. In this mosaic, two $T_2$’s (similarly $T_3$’s) cannot be placed adjacent in a row (horizontal adjacency rule), while $T_2$ and $T_3$ can be adjoined along the edges labeled with number 1 (vertical adjacency rule).

![Figure 3. Conversion of the IVS in Figure 1 to an IVS $m \times n$–mosaic](image)

A mosaic is said to be *suitably adjacent* if any pair of mosaic tiles sharing an edge satisfies both adjacency rules. A suitably adjacent $m \times n$–mosaic is called an *IVS $m \times n$–mosaic* if it additionally satisfies the boundary state requirement. The following one-to-one conversion arises naturally.

**One-to-one conversion:** There is a one-to-one correspondence between IVSs in $G_{m \times n}$ and IVS $m \times n$–mosaics. Furthermore, the number of vertices in an IVS is equal to the number of $T_2$ mosaic tiles in the corresponding IVS $m \times n$–mosaic.

3. **Stage 2: State matrix recursion formula**

Now we introduce two types of state matrices for suitably adjacent mosaics.

3.1. **States and state polynomials.** A *state* is a finite sequence of two numbers 0 and 1, or three letters a, b and c. Let $p \leq m$ and $q \leq n$ be positive
integers, and consider a suitably adjacent \( p \times q \)–mosaic \( M \). We use \( d(M) \) to denote the number of appearances of \( T_2 \) tiles in \( M \). The \( b \)–state \( s_b(M) \) (\( t \)–state \( s_t(M) \)) is the state of length \( p \) obtained by reading off numbers on the bottom (top, respectively) boundary edges from right to left, and the \( l \)–state \( s_l(M) \) (\( r \)–state \( s_r(M) \)) is the state of length \( q \) obtained by reading off letters on the left (right, respectively) boundary edges as shown in Figure 4.

![Figure 4](image)

**Figure 4.** A suitably adjacent 4\( \times \)3–mosaic with four state indications: \( s_b(M) = 1010 \), \( s_t(M) = 0010 \), \( s_l(M) = \text{abc} \), and \( s_r(M) = \text{aab} \).

Given a triple \( (s_r,s_b,s_t) \) of \( r \)–, \( b \)– and \( t \)–states, we associate the state polynomial:

\[
S_{(s_r,s_b,s_t)}(z) = \sum k(d)z^d,
\]

where \( k(d) \) equals the number of all suitably adjacent \( p \times q \)–mosaics \( M \) such that \( d(M) = d \), \( s_r(M) = s_r \), \( s_b(M) = s_b \) and \( s_t(M) = s_t \). Note that there is no restriction on the \( l \)–state of \( M \).

### 3.2. Bar state matrices.

Now consider suitably adjacent \( p \times 1 \)–mosaics, which are called bar mosaics. Bar mosaics of length \( p \) have \( 2^p \) kinds of \( b \)– and \( t \)–states, especially called bar states. We arrange all bar states, which are binary digits, as usual. For \( 1 \leq i \leq 2^p \), let \( \epsilon_i^p \) denote the \( i \)–th bar state of length \( p \). The first bar state \( \epsilon_1^p = 00 \cdots 0 \) is called trivial.

**Bar state matrix** \( X_p \) \( (X = A,B,C) \) for the set of suitably adjacent bar mosaics of length \( p \) is a \( 2^p \times 2^p \) matrix \( (x_{ij}) \) given by

\[
x_{ij} = S_{(\epsilon_i^p,\epsilon_j^p)}(z),
\]

where \( x = a, b, c \), respectively. We remark that information on suitably adjacent bar mosaics is completely encoded in three bar state matrices \( A_p, B_p \) and \( C_p \).

**Lemma 4** (Bar state matrix recursion lemma). **Bar state matrices** \( A_p, B_p \) and \( C_p \) are recursively obtained by

\[
A_{k+1} = \begin{bmatrix} A_k + B_k + C_k & \mathbb{O}_k \\ \mathbb{O}_k & \mathbb{O}_k \end{bmatrix},
\]

\[
B_{k+1} = \begin{bmatrix} \mathbb{O}_k & \mathbb{O}_k \\ \mathbb{O}_k & \mathbb{O}_k \end{bmatrix}
\]

and

\[
C_{k+1} = \begin{bmatrix} \mathbb{O}_k & A_k + B_k \\ \mathbb{O}_k & \mathbb{O}_k \end{bmatrix}.
\]
A Proof.

of Lemmas 5 and 6 in [14] with slight modification. State matrices.

3.3. Lemma 5 (State matrix multiplication lemma)

Consider the matrix

\[ A_k = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_k = \begin{bmatrix} 0 & 0 \\ z & 0 \end{bmatrix} \text{ and } C_k = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}. \]

Note that we may start with matrices \( A_0 = [1] \) and \( B_0 = C_0 = [0] \) instead of \( A_1, B_1 \) and \( C_1 \). Our proofs of Lemmas 4 and 5 parallel respectively those of Lemmas 5 and 6 in [14] with slight modification.

Proof. We use induction on \( k \). A straightforward observation on the mosaic tiles establishes the lemma for \( k = 1 \).

Assume that bar state matrices \( A_k, B_k \) and \( C_k \) satisfy the statement. Consider the matrix \( B_{k+1} \), which is of size \( 2^{k+1} \times 2^{k+1} \). Partition this matrix into four block submatrices of size \( 2^k \times 2^k \), and consider the 21-submatrix of \( B_{k+1} \), i.e., the \((2,1)\)-component in the \( 2 \times 2 \) array of the four blocks. The \((i,j)\)-entry of the 21-submatrix is the state polynomial \( S_{(b,1c^k,0c^k)}(z) \) where \( 1c^k \) (similarly \( 0c^k \)) is a bar state of length \( k+1 \) obtained by concatenating two bar states 1 and \( k^j \). A suitably adjacent \((k+1)\times 1\)-mosaic corresponding to this triple \((b,1c^k,0c^k)\) must have tile \( T_2 \) at the place of the rightmost mosaic tile, and so its second rightmost tile cannot be \( T_2 \) by the horizontal adjacency rule. Thus the \( r \)-state of the second rightmost tile is either a \( b \) or \( c \). By considering the contribution of the rightmost tile \( T_2 \) to the state polynomial, one easily gets

\[ S_{(b,1c^k,0c^k)}(z) = z \cdot ((i,j)\text{-entry of } (A_k + C_k)). \]

Thus the 21-submatrix of \( B_{k+1} \) is \( zA_k + zC_k \). The same argument gives Table 2 presenting all possible twelve cases as desired. \( \square \)

| Submatrix for \( (s_r, s_b, s_i) \) | Rightmost tile | Submatrix |
|----------------------------------|----------------|-----------|
| \( A_{k+1} \) 11-submatrix \( \langle n,0\cdots,0\cdots \rangle \) | \( T_1 \) | \( A_k + B_k + C_k \) |
| \( B_{k+1} \) 21-submatrix \( \langle b,1\cdots,0\cdots \rangle \) | \( T_2 \) | \( zA_k + zC_k \) |
| \( C_{k+1} \) 12-submatrix \( \langle c,0\cdots,1\cdots \rangle \) | \( T_3 \) | \( A_k + B_k \) |
| The other nine cases None | None | \( \varnothing_k \) |

Table 2. Twelve submatrices of \( A_{k+1}, B_{k+1} \) and \( C_{k+1} \)

3.3. State matrices. State matrix \( Y_{m \times q} \) for the set of suitably adjacent \( m \times q \)-mosaics is a \( 2^m \times 2^m \) matrix \((y_{ij})\) given by

\[ y_{ij} = \sum S_{(s_r, \bar{e}^m, \bar{e}^m)}(z), \]

where the summation is taken over all \( r \)-states \( s_r \) of length \( q \).

Lemma 5 (State matrix multiplication lemma).

\[ Y_{m \times n} = (A_m + B_m + C_m)^n. \]

Proof. Use induction on \( n \). For \( n = 1 \), \( Y_{m \times 1} = A_m + B_m + C_m \) since \( Y_{m \times 1} \) counts suitably adjacent \( m \times 1 \)-mosaics with any \( r \)-states. Assume that \( Y_{m \times k} = (A_m + B_m + C_m)^k \). Consider a suitably adjacent \( m \times (k+1) \)-mosaic.
\( M^{m \times (k+1)} \). Split it into two suitably adjacent \( m \times k \)- and \( m \times 1 \)-mosaics \( M^{m \times k} \) and \( M^{m \times 1} \) by tearing off the topmost bar mosaic. By the vertical adjacency rule, the \( t \)-state of \( M^{m \times k} \) and the \( b \)-state of \( M^{m \times 1} \) must coincide as shown in Figure 5.

\[
\begin{array}{c|ccc}
M^{m \times 1} & 0 & 1 & 0 & 0 \\
\hline
M^{m \times k} & & & & \\
\hline
S_t & 0 & 1 & 0 & 0 & j-th \\
\hline
S_b & 0 & 1 & 0 & 0 & i-th \\
\end{array}
\]

\[
\text{r-th among } 2^m \text{ choices}
\]

**Figure 5. Expanding } M^{m \times k} \text{ to } M^{m \times (k+1)}

Let \( Y^{m \times (k+1)} = (y_{ij}) \), \( Y^{m \times k} = (y'_{ij}) \) and \( Y^{m \times 1} = (y''_{ij}) \). Note that \( y_{ij} \) is the state polynomial for the set of suitably adjacent \( m \times (k+1) \)-mosaics \( M \) which admit splittings into \( M^{m \times k} \) and \( M^{m \times 1} \) satisfying \( s_b(M) = s_b(M^{m \times k}) = \epsilon_i^m \), \( s_t(M) = s_t(M^{m \times 1}) = \epsilon_j^m \), and \( s_t(M^{m \times k}) = s_b(M^{m \times 1}) = \epsilon_r^m \) \((1 \leq r \leq 2^m)\). Thus,

\[
y_{ij} = \sum_{r=1}^{2^m} y'_{ir} \cdot y''_{rj}.
\]

This implies

\[
Y^{m \times (k+1)} = Y^{m \times k} \cdot Y^{m \times 1} = (A_m + B_m + C_m)^{k+1},
\]

and the induction step is finished. \( \square \)

4. **Stage 3: State matrix analyzing**

We analyze state matrix \( Y_{m \times n} \) to find the generating function \( P_{m \times n}(z) \).

**Proof of Theorem** Let \((i, j)\)-entry of \( Y_{m \times n} \) be the state polynomial for the set of suitably adjacent \( m \times n \)-mosaics \( M \) with \( s_b(M) = \epsilon_i^m \) and \( s_t(M) = \epsilon_j^m \) (no restriction on \( s_l(M) \) and \( s_r(M) \)). According to the boundary state requirement, IVSs in \( G_{m \times n} \) are converted into suitably adjacent \( m \times n \)-mosaics \( M \) with trivial \( t \)-state as the left picture in Figure 6. This means \( s_b(M) = \epsilon_i^m \) \((i \text{ takes any value of } 1, \ldots, 2^m)\) and \( s_t(M) = \epsilon_j^m \). Thus the sum of the state polynomials in the first column of \( Y_{m \times n} \) represents the generating function \( P_{m \times n}(z) \). In short, we get

\[
P_{m \times n}(z) = \text{entry sum of the first column of } Y_{m \times n}.
\]

On the other hand, as the right picture in Figure 6, IVSs \( m \times n \)-mosaics can also be converted to suitably adjacent \( m \times (n+1) \)-mosaics with trivial \( b \)- and \( t \)-states. Therefore,

\[
P_{m \times n}(z) = (1,1)\text{-entry of } Y_{m \times (n+1)}.
\]
These equalities combined with Lemmas 4 and 5 complete the proof.

Note that the recurrence relation in Lemma 4 is easily translated into that of Theorem 1 by replacing $A_k + B_k + C_k$, $A_k + B_k$ and $A_k + C_k$ with $A_k$, $B_k$ and $C_k$, respectively.

\[\square\]

Figure 6. Analyzing state matrix $Y_{m \times n}$

5. BIVS mosaics

In this section we use the state matrix recursion algorithm to enumerate bipartite independent vertex sets. We follow the argument in the proof of Theorem 1.

Proof of Theorem 2. We reformulate the state matrix recursion algorithm by using seven mosaic tiles $T_1, \ldots, T_7$ illustrated in Figure 7. Their horizontal and vertical side edges are labeled with three numbers 0, 1, 2 and seven letters a, b, c, d, e, f, g, respectively.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure7.png}
\caption{Seven mosaic tiles}
\end{figure}

The same vertical adjacency rule and boundary state requirement are employed, while the horizontal adjacency rule and the corresponding one-to-one conversion are slightly changed as follows.

**Horizontal adjacency rule:** Abutting edges of adjacent mosaic tiles in a row are not labeled with any of the following pairs of letters: b/b, c/c, d/d, e/e, f/f, g/g, b/g, g/b, c/e, e/c, d/e, e/d, f/g, g/f.

**One-to-one conversion:** There is a one-to-one correspondence between BIVSs in $G_{m \times n}$ and BIVS $m \times n$-mosaics. Furthermore, the number of white (black) vertices in a BIVS is equal to the number of $T_4$ and $T_5$ ($T_6$ and $T_7$, respectively) mosaic tiles in the corresponding BIVS $m \times n$-mosaic.
In the second stage, we find the corresponding bar state matrix recursion lemma (Lemma 7) and state matrix multiplication lemma (Lemma 5) as in Section 3.

Lemma 6. Bar state matrices \( A_p, \ldots, G_p \) are obtained by the recurrence relations:

\[
\begin{align*}
A_{k+1} &= A_1 \otimes (A_k + B_k + C_k + D_k + E_k + F_k + G_k) \\
B_{k+1} &= B_1 \otimes (A_k + C_k + D_k + E_k + F_k) \\
C_{k+1} &= C_1 \otimes (A_k + B_k + D_k + F_k + G_k) \\
D_{k+1} &= D_1 \otimes (A_k + B_k + C_k + F_k + G_k) \\
E_{k+1} &= E_1 \otimes (A_k + B_k + F_k + G_k) \\
F_{k+1} &= F_1 \otimes (A_k + B_k + C_k + D_k + E_k) \\
G_{k+1} &= G_1 \otimes (A_k + C_k + D_k + E_k)
\end{align*}
\]

with seed matrices

\[
\begin{align*}
A_1 &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, & B_1 &= \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, & C_1 &= \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, & D_1 &= \begin{bmatrix} 0 & 0 & 0 \\ x & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \\
E_1 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & x \end{bmatrix}, & F_1 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ y & 0 & 0 \end{bmatrix} \text{ and } G_1 &= \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & y & 0 \end{bmatrix}.
\end{align*}
\]

Lemma 7.

\[ Y_{m \times n} = (A_m + B_m + C_m + D_m + E_m + F_m + G_m)^n. \]

In the third stage, we analyze this state matrix as in Section 4 and as done there, we replace \( A_k + B_k + C_k + D_k + E_k + F_k + G_k \), \( A_k + C_k + D_k + E_k + F_k \), \( A_k + B_k + D_k + F_k + G_k \), \( A_k + B_k + C_k + F_k + G_k \), \( A_k + B_k + F_k + G_k \), \( A_k + B_k + C_k + D_k + E_k \), \( A_k + C_k + D_k + E_k \) with \( A_k, \ldots, G_k \), respectively, to complete the proof. \( \square \)

6. HARD SQUARE CONSTANT

To prove Theorem 3 we need the following result called Fekete’s lemma with slight modification.

Lemma 8. [14, Lemma 7] Suppose that a double sequence \( \{a_{m,n}\}_{m,n \in \mathbb{N}} \) with \( a_{m,n} \geq 1 \) satisfies \( a_{m_1+m_2,n} \leq a_{m_1,n} \cdot a_{m_2,n} \leq a_{m_1+m_2+1,n} \) and \( a_{m,n_1+n_2} \leq a_{m,n_1+n_2+1} \) for all \( m, m_1, m_2, n, n_1 \) and \( n_2 \). Then

\[
\lim_{m,n \to \infty} \frac{1}{a_{m,n}} = \inf_{m,n \in \mathbb{N}} \frac{1}{(a_{m,n})^{(n+1)/(m+1)}},
\]

provided that the supremum exists.

Proof of Theorem 3 Consider the Merrifield–Simmons index \( \sigma(G_{m \times n}) \), simply denoted by \( \sigma_{m \times n} \). Obviously, \( \sigma_{m \times n} \geq 1 \) for all \( m, n \). The submultiplicative inequality \( \sigma_{m_1+m_2 \times n} \leq \sigma_{m_1 \times n} \cdot \sigma_{m_2 \times n} \) is obvious because we can always split an IVS \( (m_1 + m_2) \times n \)- mosaic into a unique pair of IVS \( m_1 \times n \)- and \( m_2 \times n \)-mosaics. On the other hand, any two IVS \( m_1 \times n \)- and \( m_2 \times n \)-mosaics can be adjoined horizontally to create a new IVS \( (m_1 + m_2 + 1) \times n \)-mosaic.
by inserting between them a $1 \times n$–mosaic consisting only of $T_1$ tiles as in Figure 8. Therefore \( \sigma_{m \times 1} \cdot \sigma_{n \times n} \leq \sigma_{(m+1) \times n \times n} \).

The inequality \( \sigma_{m \times (n_1 + n_2)} \leq \sigma_{m \times n_1} \cdot \sigma_{m \times n_2} \) is also obvious because we can always split an IVS $m \times (n_1 + n_2)$–mosaic into a unique pair of IVS $m \times n_1$– and $m \times n_2$–mosaics by deleting all vertices on the top boundary of the bottom-side $m \times n_1$–mosaic. On the other hand, any two IVS $m \times n_1$– and $m \times n_2$–mosaics $M^{m \times n_1}$ and $M^{m \times n_2}$ can be adjoined vertically to create a new IVS $m \times (n_1 + n_2 + 1)$–mosaic by inserting a suitably adjacent bar $m \times 1$–mosaic whose $b$–state is trivial as $s_b(M^{m \times n_1})$ and $t$–state is $s_b(M^{m \times n_2})$ as in Figure 8. Therefore \( \sigma_{m \times n_1} \cdot \sigma_{m \times n_2} \leq \sigma_{m \times (n_1 + n_2 + 1)} \). Since we use only three mosaic tiles at each site, \( \sup_{m,n}(\sigma_{m \times n})^{(m+1)(n+1)} \leq 3 \), and now apply Lemma 8.

For the bipartite Merrifield–Simmons index \( \beta(G_{m \times n}) \), this proof applies verbatim. □
