(Dated: December 8, 2015)

We investigate the decay of $f_1(1285) \rightarrow \pi K\bar{K}$ with the assumption that the $f_1(1285)$ is dynamically generated from the $K^*\bar{K}-cc$ interaction. In addition to the tree level diagrams that proceed via $f_1(1285) \rightarrow K^*\bar{K}-cc \rightarrow \pi K\bar{K}$, we take into account also the final state interactions of $K\bar{K} \rightarrow K\bar{K}$ and $\pi K \rightarrow \pi K$. The partial decay width and mass distributions of $f_1(1285) \rightarrow \pi K\bar{K}$ are evaluated. We get a value for the partial decay width which, within errors, is in fair agreement with the experimental result. The contribution from the tree level diagrams is dominant, but the final state interactions have effects in the mass distributions. The predicted mass distributions are significantly different from phase space and tied to the $K^*\bar{K}-cc$ nature of the $f_1(1285)$ state.

PACS numbers:

I. INTRODUCTION

The interaction of pseudoscalar mesons with vector mesons can be tackled with the use of chiral Lagrangians. These chiral Lagrangians are also obtained by using the local hidden gauge approach, exchanging vector mesons between the vectors and the pseudoscalars in the limit of small momentum transfers. Interesting developments using these Lagrangians within a unitary scheme in coupled channels led to the generation of the low lying axial vectors from the interaction of these mesons, which qualify them as dynamically generated states. The states could qualify as kind of molecular states of a pair of mesons, or at least one can claim that this is the dominant component in the wave function. One of these resonances, the $a_1(1260)$ has been further investigated and found to require some extra components, presumably $q\bar{q}$, to explain some decay properties. The extrapolation of these ideas to the charmonium sector has also produced new states, as the $D_{13}^*(2460)$, generated from $KD^*$. QCD lattice simulations produce this latter state by using $KD^*$ interpolators, suggesting a molecular nature for this resonance. A more quantitative study has been done in Ref. and within errors of about 25% one determines in about 60% the amount of $KD^*$ component in the wave function of that resonance. The molecular nature of some resonances is catching interest, since the structure is different than the standard $q\bar{q}$ commonly accepted for mesons, and the recent developments with QCD lattice simulations have revived this topic.

One of the cleanest example of these resonances is the $f_1(1285)$ with quantum numbers $J^P = 0^+(1^{++})$. This resonance appears very clean and precise in Ref. from the single channel $K^*\bar{K}-cc$, and the width is very small, as in the experiment, because it cannot decay into two pseudoscalar mesons (in principle $K\bar{K}$ in this case) for parity and angular momentum conservation reasons. An extension of the work of Ref. including higher order terms in the Lagrangian, has shown that the effect of the higher order terms is negligible using these theoretical tools, predictions for lattice simulations in finite volume have been done in Ref.

The width of the $f_1(1285)$ is 24 MeV, quite small for its mass, and naturally explained within the molecular picture. Then the channels contributing to it are very peculiar. For instance, the $\pi a_0(980)$ channel accounts for 36% of the width. This channel has been very well reproduced in Ref. within this molecular picture for the $f_1(1285)$, together with a similar description of the $a_0(980)$ in the chiral unitary approach from the interaction of pseudoscalar mesons. In Ref. the $\pi f_0(980)$ decay of the $f_1(1285)$ was also studied, and the rate and shape of the $\pi^+\pi^-$ mass distribution were predicted. These predictions have been confirmed in a recent BESIII experiment.

Earlier work on the scalar resonances started from seeds of $q\bar{q}$, which, after unitarization with the meson meson channels, gives room to these meson meson channels which become dominant in the wave function.

On the other hand, there is another large channel the $K\bar{K}\pi$, which also accounts for about 9% of the width. This decay channel should be tied to the $K^*\bar{K}-cc$ nature of the state. The channel $K^*\bar{K}$ is bound for the energy of the $f_1(1285)$ by about 100 MeV, hence this decay is not observed experimentally. However, the decay of the $K^*$ off shell can produce the $K\pi$ and then one has $K\bar{K}\pi$ in the final decay channel. Definitely, this decay channel is related to the coupling of the $f_1(1285)$ to the $K^*\bar{K}-cc$, and consequently to the nature of this state. Our aim in this paper is to evaluate this decay channel from this perspective. In doing so we also have to face the final
state interaction (FSI) of the $K\bar{K}$ and the $\pi K$, which we do using the chiral unitary approach \cite{21,22,32}.

Apart from the tree level contribution, the FSI leads to loops with one vector meson and two pseudoscalars. This triangular mechanism was shown to be very important in the decay of the $\eta(1405)$ to $\pi a_0(980)$ \cite{34} and the mixing with the isospin violated $\pi f_0(980)$ channel \cite{33,35} \footnote{A recent paper reviews this issue and, based on the contribution of the imaginary part of the loop, concludes that there is a reduction of the decay to the $\pi f_0(980)$ channel if the width of the $K^*$ is considered \cite{36}. We have redone the calculations including also the real parts and the reduction persists but is weaker. However, the isospin allowed $\pi a_0(980)$ is more stable and in the present case where we have a binding of the $K\bar{K}$ by 100 MeV the effect of the $K^*$ width in the isospin allowed channels is negligible.}. We follow the approach of Refs. \cite{20,35,36} to complement the tree level contribution with the final state interaction of two mesons. We show that the tree level contribution produces a decay rate of the $f_1(1285)$ to $K\bar{K}\pi$ of the right order of magnitude, while the final state interaction of two mesons is needed for a more refined result, in good agreement with the experiment, hence supporting the molecular nature of the $f_1(1285)$ resonance.

The picture that we present for the $f_1(1285)$ is somewhat unconventional, and hence the need to find support for it, or otherwise. The current trend up to now was that this resonance is a simple $q\bar{q}$ state \cite{38,39,40}. In Ref. \cite{38} the quark pair creation model is used to account for decays of this resonance in two mesons and the $\pi a_0(980)$ decay is addressed from this perspective. In Refs. \cite{39,40} the $f_1(1285)$ is assumed to belong to a nonet of $q\bar{q}$ mesons. In Ref. \cite{41} the $B^0$ and $B^0\bar{\j}$ decays into $J/\psi$ and $f_1(1285)$ are investigated and the results are interpreted in terms of a $q\bar{q}$ state, mostly made of $u$ and $d$ quarks. Yet, in none of the works quoted, or others, have we found an evaluation of the decay of this resonance into $K\bar{K}\pi$.

\section{II. Formalism}

We study the decay of $f_1(1285) \to \pi K\bar{K}$ with the assumption that the $f_1(1285)$ is dynamically generated from the $K^*\bar{K} - cc$ interaction, thus this decay can proceed via $f_1(1285) \to K^*\bar{K} - cc \to \pi K\bar{K}$. The tree level diagrams are shown in Fig. \ref{fig:diagram}

\subsection{A. Decay amplitude at tree level}

In order to evaluate the partial decay width of $f_1(1285) \to \pi K\bar{K}$, we need the decay amplitudes of the tree level diagrams shown in Fig. \ref{fig:diagram} where the process is described as the $f_1(1285)$ decaying to $K^*\bar{K} - cc$ and then the $K^*$ decaying into $K\pi$. As mentioned above, the $f_1(1285)$ results as dynamically generated from the interaction of $K^*\bar{K} - c.c..$ We can write the $f_1(1285)K^*\bar{K}$ vertex as

$$-i\tau_3 = -ig_{f_1}C_1\epsilon^\mu\epsilon_\mu',$$

where $\epsilon$ is the polarization vector of the $f_1(1285)$ state and $\epsilon'$ is the polarization vector of the $K^*$ ($\bar{K}^*$). The $g_{f_1}$ is the coupling constant of the $f_1(1285)$ to the $K^*\bar{K} - cc$ channel and can be obtained from the residue in the pole of the scattering amplitude for $KK^* - cc$ in $I = 0$. We take $g_{f_1} = 7555$ MeV in the present calculation as it comes when the pole of the $f_1$ is made to appear at the nominal mass of the $f_1(1285)$ resonance. This result is in line but a bit bigger than the value of 7230 MeV found in Ref. \cite{37}, where a global fit to the axial vectors was conducted. \footnote{In Ref. \cite{37} a coupling of $g_{f_1} = 9687$ MeV was used, but this was based on an incorrect method to evaluate the coupling. We take advantage here to say what we would get with $g_{f_1} = 7555$ MeV. We obtain $BR(f_1(1285) \to a_0(980)\pi)_{1\pi} = (19 \pm 2)\%$, where we have added some uncertainty induced by the discussion in the present work. This should be compared with the experimental value of $BR(f_1(1285) \to a_0(980)\pi) = (36 \pm 7)\%$. The agreement is, thus, at a qualitative level.}

We take the convention $C_{K\bar{K}} = C_{K\bar{K}}^\dagger$ with the standard chiral Lagrangians. Then we can easily obtain the factors $C_1$ for each diagram shown in Fig. \ref{fig:diagram}

$$C_1^{A,B} = -\frac{1}{2}; \quad C_1^{C,D} = -\frac{1}{2}; \quad C_1^{E,F} = \frac{1}{2}; \quad C_1^{G,H} = \frac{1}{2}.$$  

To compute the decay amplitude, we also need the structure of the $K^*K\pi$ vertices which can be derived using the hidden gauge symmetry Lagrangian describing the vector-pseudoscalar-pseudoscalar ($VPP$) interaction \cite{22,23}, given by

$$\mathcal{L}_{VPP} = -ig < V^\mu [P, \partial_\mu P] > ,$$

where $g = \frac{m_V}{2f}$ with $m_V \approx m_\rho$ and $f = 93$ MeV the pion decay constant. The symbol $\leftrightarrow$ stands for the trace in $SU(3)$, while the $P$ and $V$ matrices contain the nonet of pseudoscalar and vector mesons, respectively.

From the Lagrangian of Eq. \ref{eq:lagrangian}, the vertex of $K^*K\pi$ can be written as

$$-i\tau_3 = igC_2(k - p)^\mu\epsilon_\mu',$$

where $\tau_3$ is the isospin of the $K\bar{K}$, $k$ and $p$ are the momenta of the $K$ and $\pi$, respectively. The isospin of the $K_\pi$ vertex is $I = 0$. The $C_2$ matrix contains the nonet of pseudoscalar and vector mesons, respectively.

The agreement is, thus, at a qualitative level.
where $k$ and $p$ are the momenta of $\pi$ and $K$ mesons, respectively. From Eq. (3) and from the explicit expressions of the $P$ and $V$ matrices, the factors $C_2$ for each diagram shown in Fig. 1 can be obtained,

$$C_2^{A,H} = \frac{1}{\sqrt{2}}; \quad C_2^{B,C} = 1; \quad C_2^{D,E} = -\frac{1}{\sqrt{2}}; \quad C_2^{F,G} = -1.$$ (6)

We can now sum the amplitudes of the diagrams that have same final state. By means of Eqs. (11) and (12) and taking into account the values of $C_1$ and $C_2$, the decay amplitude is obtained straightforwardly:

$$M_{\text{tree}}^{A+E} = M_{\text{tree}}^{D+H} = M_{\text{tree}},$$
$$M_{\text{tree}}^{B+G} = M_{\text{tree}}^{C+F} = \sqrt{2}M_{\text{tree}},$$ (7)

with

$$M_{\text{tree}} = \frac{gg_{\pi K}}{2\sqrt{2}}\left(\frac{k+p}{m_{K*}^2} + \left(\frac{k^2 - m_{K*}^2}{m_{K*}^2}\right)(k+p)\right)\mathcal{D}_1$$
$$+ \left(-\frac{k^2 - m_{K*}^2}{m_{K*}^2}\right)\mathcal{D}_2\epsilon^\mu$$
$$= \frac{gg_{\pi K}}{2\sqrt{2}}\left(\left(\frac{k^2 - m_{K*}^2}{m_{K*}^2}\right)\mathcal{D}_1$$
$$+ \left(-\frac{k^2 - m_{K*}^2}{m_{K*}^2}\right)\mathcal{D}_2\epsilon^\mu$$
$$+ \left(-\frac{k^2 - m_{K*}^2}{m_{K*}^2}\right)\mathcal{D}_2\epsilon^\mu,$$ (8)

where

$$D_1 = \frac{1}{(k+p)^2 - m_{K*}^2 + im_{K*}\Gamma_{K*}},$$ (9)
$$D_2 = \frac{1}{(k+p')^2 - m_{K*}^2 + im_{K*}\Gamma_{K*}}.$$ (10)

Taking diagrams A) and E) for reference to calculate $M_{\text{tree}}$, the variables $p, p'$ and $k$ refer to the $K^+, K^-$ and $\pi^0$, and $\Gamma_{K*}$ is the total decay width of the $K^*$ meson.

Since the dominant decay channel of $K^*$ is $K\pi$, we can take

$$\Gamma_{K^*} = \Gamma_{\text{on}}\left(\frac{q_{\text{on}}}{q_{\text{off}}}\right)^3,$$ (11)

with $\Gamma_{\text{on}} = 49.1$ MeV, and

$$q_{\text{on}} = \frac{\lambda^{1/2}(m_{K^*}^2, m_{K^*}^2, m_{\pi}^2)}{2M_{K^*}},$$ (12)
$$q_{\text{off}} = \frac{\lambda^{1/2}(M_{\text{inv}}^2, m_{K^*}^2, m_{\pi}^2)}{2M_{\text{inv}}}\theta(M_{\text{inv}} - m_{K} - m_{\pi}),$$ (13)

where $\lambda$ is the Kålén function, with $\lambda(x,y,z) = (x-y-z)^2 - 4yz$, and $M_{\text{inv}}$ is the invariant mass of the $\pi K$ system, which is $\sqrt{(k+p)^2}$ for the $D_1$ propagator and $\sqrt{(k+p')^2}$ for $D_2$. 

FIG. 1: Tree level diagrams representing the process $f_1(1285) \rightarrow \pi K\bar{K}$. 

B. Decay amplitude for the triangular loop

In addition to the tree level diagrams shown in Fig. 1, we study also the contributions of the $K\bar{K}$ and $\pi K$ FSIs. We use the triangular mechanism contained in the diagrams shown in Fig. 2, consisting in the rescattering of the $K\bar{K}$ and $\pi K$ pairs. Since the $f_1(1285)$ has $I = 0$, considering only isospin conserving terms, the $K\bar{K}$ will be in $I = 1$ and the $\pi K$ in $I = 1/2$. The rescattering of the $K\bar{K}$ and $\pi K$ pairs with this isospin dynamically generates in coupled channels the $a_0(980)$ and $\kappa(800)$ resonances, respectively. We write for simplicity the $K\bar{K} \to K\bar{K}$ and $\pi K \to \pi K$ rescattering amplitudes as,

$$t_{K\bar{K}}^{FSI}(M_{K\bar{K}}) = t_{K\bar{K}\to K\bar{K}}^{I=1}(M_{K\bar{K}}),$$

$$t_{\pi K}^{FSI}(M_{\pi K}) = t_{\pi K\to \pi K}^{I=1/2}(M_{\pi K}),$$

where $M_{K\bar{K}}$ and $M_{\pi K}$ are the invariant masses for the $K\bar{K}$ and $\pi K$ systems, respectively. The quantities $t_{K\bar{K}\to K\bar{K}}^{I=1}$ and $t_{\pi K\to \pi K}^{I=1/2}$ stand for the scattering amplitudes of $K\bar{K} \to K\bar{K}$ in $I = 1$ and $\pi K \to \pi K$ in $I = 1/2$, respectively, and they can be obtained using the Bethe-Salpeter equation

$$t = (1 - VG)^{-1}V,$$

with the potential $V$ taken from Ref. [21]. The $G$ function in the above equation is the loop function for the propagators of the intermediate particles

$$G(P^2) = \int \frac{d^4q}{(2\pi)^4} \frac{1}{q^2 - m_1^2 + i\epsilon} \frac{1}{(P - q)^2 - m_2^2 + i\epsilon},$$

where $P$ is the total four-momentum ($s = P^2$ is the invariant mass square of the two particles in the loop) and $m_1, m_2$ the masses of the particles in the considered channel. We take $K\bar{K}$ and $\pi \eta$ channels for the case of $K\bar{K}$ FSI, while for $\pi K$ FSI, we take $\pi K$ and $\eta K$ channels. After the regularization by means of a cutoff [21], we obtain

$$G(s) = \int_{|q|<q_{\text{max}}} \frac{d^3q}{(2\pi)^3} \frac{1}{2\omega_1 \omega_2} \frac{1}{s - (\omega_1 + \omega_2)^2 + i\epsilon},$$

with $\omega_i = \sqrt{|q|^2 + m_i^2}$. For a good description of $a_0(980)$ and $\kappa(800)$ we take a cutoff $q_{\text{max}} = 900$ MeV, for both $K\bar{K}$ and $\pi K$ FSIs.

With the ingredients given above, we can explicitly write the decay amplitude for the diagrams in Fig. 2. As for the tree level case, we sum the diagrams with the same final state, is then given by

$$M_{\text{FSI}}^{K\bar{K}} = -\frac{gg_{f_1}}{2\sqrt{2}} (2I_1 + I_2)2t_{K\bar{K}\to K\bar{K}}^{I=1}(M_{K\bar{K}})\xi \cdot \vec{k},$$

with $M_{K\bar{K}} = \sqrt{(p + p')^2}$. Here we have summed explicitly the contributions of four diagrams corresponding to the intermediate states $K^+K^-K\bar{K}$, $K^{*-}K^-K\bar{K}$, $K^0\bar{K}^0K\bar{K}$, $K^+K^-K\bar{K}$ and $K^{*0}K^0K\bar{K}$, easily done taking into account the $C_1$ and $C_2$ coefficients and the fact that

$$t_{K\bar{K}\to K\bar{K}}^{I=1} = t_{K\bar{K}\to K\bar{K}}^{I=1} - t_{K\bar{K}\to K\bar{K}}^{I=1} = t_{K\bar{K}\to K\bar{K}}^{I=1} - t_{K\bar{K}\to K\bar{K}}^{I=1},$$

with the phase convention $|K^-\rangle = -|1/2, -1/2\rangle$. The quantities $I_1$ and $I_2$ for the case of $M_{\text{FSI}}^{K\bar{K}}$ are given by

FIG. 2: Triangular loop contributions to the $f_1(1285) \to \pi K\bar{K}$ decay.
where $\omega(q) = \sqrt{q^2 + m_K^2}$, $\omega'(q) = \sqrt{(q + \vec{k})^2 + m_k^2}$, and $\omega''(q) = \sqrt{(q + \vec{k} + \vec{p})^2 + m_k^2}$, are the energies of the $K(\bar{K})$, $K(K)$, and $K^{*}(\bar{K})$ in the triangular loop, respectively. A simple Clebsch-Gordan coefficients. Besides, the cosine $\cos \theta_K$ stands for the average over the polarizations of the initial $f_1(1285)$ and this leads, after considering the $C_1$ and $C_2$ coefficients to the combination $t_{\pi^0K^0} \rightarrow t_{\pi^0K^0}$, proportional to the $t^{*K \rightarrow K^*}$. The sum of the first and second diagram with $\pi^0K^+K^-$ in the final state is then easily done and can be cast as

$$
M^K_{F_{\pi K}} = \frac{99_{f1}}{2\sqrt{2}} (I_1' + I_2') + \frac{99_{f1}}{2\sqrt{2}} (I_1'' + I_2'') \text{ with weights 1, 2, and 2},$$

where now $I_1'$, $I_2'$ are evaluated with Eqs. (21) and (22) replacing one kaon propagator by a pion and simply putting $\omega'(q) = \sqrt{(q + \vec{p})^2 + m_k^2}$ and doubling $k^0$ by $p^0$. Similarly $I_1''$ and $I_2''$ are also evaluated with Eqs. (21) and (22) putting $\omega''(q) = \sqrt{(q + \vec{p} + \vec{k})^2 + m_k^2}$ and substituting $k^0$ by $p^0$. The integrals $I_1'$, $I_2'$ of $|p|$ have weights 1, 2, which can be written in terms of the invariant masses $M^{(1)}_{\pi K} = \sqrt{(k + p)^2}$ and $M^{(2)}_{\pi K} = \sqrt{(k + p)^2}$ respectively, similarly as done before for the $K K$ interaction terms.

The relative minus sign between Eqs. (19) and (20) is easily traced back to the sign of the $K^* \rightarrow K\pi$ when we have either the $K$ or $\pi$ in the loop.

### III. NUMERICAL RESULTS

With the decay amplitudes obtained above, we can easily get the total decay widths of $f_1(1285) \rightarrow \pi K\bar{K}$, which is

$$
\Gamma = \frac{1}{64\pi^3 M_{f_1}} \int \int d\omega_{K^+} d\omega_{K^-} \sum |M|^2 \times \rho(1 - \cos \theta_{KK}) \theta(M_{f_1} - \omega_{K^+} - \omega_{K^-} - m_\pi),
$$

where $M$ is the full amplitude of the process $f_1(1285) \rightarrow \pi^0K^+K^-$ including the FSI,

$$
M = M_{\text{tree}} + M_{FSI}^K + M_{FSI}^{\pi K}.
$$

with $M_{f_1} = 1281.9$ MeV the mass of $f_1(1285)$ state and $\omega_{K^+} = \sqrt{m_K^2 + p^2}$ and $\omega_{K^-} = \sqrt{m_K^2 + p^2}$ the energies of the $K^+$ and $K^-$ mesons, respectively. The symbol $\sum$ stands for the average over the polarizations of the initial $f_1(1285)$ state. The factor 6 in the formula of $\Gamma$ accounts for the different final charges for $\pi K K$: $\pi^0K^+K^-$, $\pi^0K^0K^-$, $\pi^+K^0K^-$, $\pi^-K^+K^0$, and $\pi^0K^0K^0$, having weights 1, 2, and 1, respectively, which can be easily obtained using simple Clebsch-Gordan coefficients. Besides, the $\cos \theta_{KK}$ is defined by energy conservation as

$$
\cos \theta_{KK} = \frac{1}{2|p||\vec{p}'|} \left[ |M_{f_1}^2 + 2m_k^2 - 2M_{f_1}(\omega_{K^+} + \omega_{K^-}) + 2\omega_{K^+}\omega_{K^-} - m_\pi^2 | \right].
$$

With the full amplitude of Eq. (26), the numerical result for the partial decay width is, using $g_{f_1} = 7555$ MeV, $\Gamma = 1.9$ MeV, which corresponds to a branching ratio

$$
B.R. [f_1(1285) \rightarrow \pi K\bar{K}] = 7.8%. \quad (27)
$$

If we use the coupling of Ref. [2], $g_{f_1} = 7230$ MeV, then we get $\Gamma = 1.74$ MeV, corresponding to a branching ratio

$$
B.R. [f_1(1285) \rightarrow \pi K\bar{K}] = 7.2%. \quad (28)
$$

This gives a band of theoretical results of

$$
B.R. [f_1(1285) \rightarrow \pi K\bar{K}] = (7.2 - 7.8)\%.
$$

(29)
which is in fair agreement with the experimental value: 
\((9.0 \pm 0.4)\%\) \cite{32, 43, 46}. The result would be 9.1%, with
the big \(g_{f_1}\) coupling, if we considered only the tree level
diagrams. This indicates that the contribution from the
FSIs is small. This occurs because of the relative minus
sign in Eqs. \((19)\) and \((23)\), which makes the effects of the
FSIs for \(K\bar{K}\) and \(\pi K\) go in opposite directions bringing
a partial cancelation in \(\Gamma\).

We should take into account that in order to get the
\(f_1(1285)\) state, cut offs of the order of 1000 MeV in the \(G\)
function of \(K\bar{K}\) are used. On the other hand for the \(G\)
function of \(K\bar{K}\) and \(\pi K\) a cut off of 900 MeV was used.
In the triangular loop function of Fig. 2 we have then
\(\theta(1000-|\vec{q}|) \theta(900-|\vec{q}|) = \theta(900-|\vec{q}|)\) (in MeV). This jus-
tifies the choice of \(q_{\text{max}}\) in that loop function. We can see
the variation of our results by changing these cut off in
a range such that the masses of the \(f_1(1285)\) and \(a_0(980)\)
are not much changed with respect to the experimental
values. In this sense, changes of \(q_{\text{max}}\) from 980 MeV to
1040 MeV bring changes in the mass of the \(f_1(1285)\) by
12 MeV and only 1% changes in the couplings. These
changes are smaller than the range of couplings accepted
in Eq. \((29)\). Similarly, changes in \(q_{\text{max}}\) for \(a_0(980)\) from
860 MeV to 940 MeV change the mass of the \(a_0(980)\) in
7 MeV. Reevaluating the branching ratios with values of
\(q_{\text{max}}\) within this range, change the result that we quote
in Eq. \((29)\) to

\[ B.R.[f_1(1285) \to \pi K\bar{K}] = (7.2 - 8.3)\%, \quad (30) \]

with the upper limit a little closer to the experimental
value.

Next, we study the invariant mass distribution of the
\(f_1(1285) \to \pi^0 K^+ K^-\) decay to see the effect of the \(K^*\)
propagator in the tree level and of the \(K\bar{K}\) and \(\pi K\) FSIs.
The invariant mass distributions are given by the for-

\[ \frac{d\Gamma}{dM_{K^+ K^-}} = \frac{M_{K^+ K^-}}{64\pi^3 M_{f_1}^2} \int d\omega_{K^+} \sum |M|^2 \theta(1 - \cos^2 \theta_{K\bar{K}}) \times \theta(M_{f_1} - \omega_{K^+} - \omega_{K^-} - m_{\pi}) \theta(\omega_{K^-} - m_K), \quad (31) \]

\[ \frac{d\Gamma}{dM_{\pi^0 K^+}} = \frac{M_{\pi^0 K^+}}{64\pi^3 M_{f_1}^2} \int d\omega_{K^+} \sum |M|^2 \theta(1 - \cos^2 \theta_{K\bar{K}}) \times \theta(M_{f_1} - \omega_{K^+} - \omega_{K^-} - m_{\pi}) \theta(\omega_{K^-} - m_K), \quad (32) \]

where

\[ \omega_{K^-} = \frac{1}{2M_{f_1}}(M_{K^+ K^-}^2 + M_{f_1}^2 - m_\pi^2) - \omega_{K^+}, \quad (33) \]

for \(\frac{d\Gamma}{dM_{K^+ K^-}}\), while

\[ \omega_{K^-} = \frac{1}{2M_{f_1}}(M_{f_1}^2 + M_{\pi^0 K^+}^2 - M_{\pi^0 K^+}^2), \quad (34) \]

for \(\frac{d\Gamma}{dM_{\pi^0 K^+}}\).

The results for \(\frac{d\Gamma}{dM_{K^+ K^-}}\) and \(\frac{d\Gamma}{dM_{\pi^0 K^+}}\) are shown in
Fig. 3 and Fig. 4 respectively. It is very interesting to

We show there the results assuming just a phase space distribution \((\sum |M|^2\) in Eqs. \((31)\) and \((32)\) is set to a constant),
and with the tree level or tree level plus final state in-
teraction of \(K\bar{K}\) and \(\pi K\). For the sake of comparison,
the curves are normalized to the same \(\Gamma\). In Fig. 3
we see that the tree level alone shows a distinct shape, very
different from phase space, with a peak at low \(M_{K^+ K^-}\).
This must be attributed to the effect of the \(K^*\) off shell
propagator. The implementation of FSI, particularly the
\(K\bar{K}\) in this case, is responsible for a further shift of the
mass distribution to lower invariant masses, closer to the
\(K\bar{K}\) threshold, where the \(a_0(980)\) resonance appears.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig3.png}
\caption{The mass distribution \(\frac{d\Gamma}{dM_{K^+ K^-}}\) for \(f_1(1285) \to \pi^0 K^+ K^-\) as a function of the invariant mass of the \(K^+ K^-\) system.}
\end{figure}

In Fig. 3 where the \(\pi K\) invariant mass distribution is plotted, we see a similar behaviour. The tree level
alone already produces a shape quite different from phase
space, with a peak at high values of \(M_{\pi K}\), to be at-
tributed once again to the off shell \(K^*\) propagator. The
implementation of FSI, particularly the \(\pi K\) in this case,
pushes the peak of the mass distributions to higher \(M_{\pi K}\),
closer to the region where the \(\kappa(800)\) resonance appears.

The two figures show how the most drastic change in
the shape of the two mass distributions is already caused
by the tree level alone and, as mentioned before, this is
tied to the \(K^*\) propagators, which appears at tree level
because of the \(K^* K - cc\) nature of the \(f_1(1285)\) state
that we have assumed. These mass distributions have
not been measured yet and it is clear from the present
study that their observation would be very important to
determine the nature of this resonance.

So far we have assumed that the \(f_1(1285)\) resonance is
fully made from \(K\bar{K}\). There are hints that the res-
sonance could have also other components. Indeed, in

\[ \sum |M|^2 \]
J/ψ decays mostly made of strange quarks in our system. It is interesting to note that in Ref. [44] the molecular component would show up in other reactions. In this sense, the molecular component of the wave function, and other components for this resonance in the B decays would be most welcome after the discussion made here.

the study of this resonance in finite volume [19] it was shown that applying the compositeness sum rule to this case with the chiral potential, the KKmolecular component accounted for about 50% of the probability of the wave function, but there could still be a sizable fraction for other non KK* components. The size of these components is uncertain because it relies on the energy dependence contained in the chiral potential and it is unclear that this accounts for missing channels (see Ref. [50]), but it really hints at the possibility to have some non negligible non KK* molecular component in the f1(1285) wave function. This might seem to be in conflict with our claims of a basically molecular state for this resonance. This requires some explanation. Different parts of the wave function revert in different ways on certain observables. The easiest such case is the nucleon form factor, which at low momentum transfer is dominated by the meson baryon components of the nucleon, while at high momentum transfer it is the core of quarks that is responsible for it [51, 52]. In this sense, it is logical that the decay of the f1(1285) into Kπ states is mostly due to the KK* molecular component of the wave function, and other components would show up in other reactions. In this sense it is interesting to note that in Ref. [14] the B0 and B*0 decays into J/ψ and f1(1285) are investigated and the interpretation in terms of a qq state leads to a f1(1285) state mostly made of u and d quarks. In our case we have four quarks to start with and a sizable fraction of strange quarks in our KK* molecular component, so the models seem to be contradictory. Yet, one must recall that in this latter case we have production of the resonance in B decays and the resonance must be formed starting from a qq component. The investigation done in Refs. [53, 54] of the B decays, and the ratio of the rates of $B^0 \to J/\psi f_0(500)$ [55] and $B^0 \to J/\psi \phi$ [52], show that the hadronization of the primary qq component to give two mesons has a penalty factor that reverts into a factor of 0.37 decrease in the partial decay width. In this sense, the decays of heavy mesons leading to light ones might reveal themselves into a source of information on the non molecular components of states like the present one. Further research considering both the molecular and qq components for this resonance in the B decays would be most welcome after the discussion made here.

IV. SUMMARY

In this work, we evaluate the partial decay width of the f1(1285) → πKK with the assumption that the f1(1285) is dynamically generated from the K*KK → cc interaction. The tree level diagrams proceeding via f1(1285) → K*KK → cc → πKK are considered. Besides, we also take into account the final state interactions of KK → KK and πKK → πK. It is found that the contributions from the FSIs are small compared to the tree level diagrams to the partial decay width, but they change the mass distributions of the f1(1285) → πKK decay.

The result that we obtained for the width is compatible with experiment within errors. Yet, we find some relevant features in the KK and πKK mass distributions, which turn out to be very different from phase space. The FSI is partially responsible for the shapes obtained but we found that the tree level contribution, which is dominant in the process, is mostly responsible for this different shape, which must be attributed to the off shell K* propagator appearing in the process under the assumption that the f1(1285) is a K*KK → cc molecule. The experimental observations of those mass distributions would then provide very valuable information on the relevance of this component in the f1(1285) wave function.

Acknowledgments

One of us, E. O., wishes to acknowledge support from the Chinese Academy of Science (CAS) in the Program of Visiting Professorship for Senior International Scientists (Grant No. 2013T2J0012).
