FAK Is Required for c-Met/β-Catenin-Driven Hepatocarcinogenesis

Na Shang,1 Maribel Arteaga,1 Ali Zaidi,1 Jimmy Stauffer,2 Scott J. Cotler,3 Nancy J. Zeleznik-Le,3 Jiwang Zhang,4 and Wei Qiu1

Hepatocellular carcinoma (HCC) is the third most common cause of cancer death worldwide and most patients with HCC have limited treatment options. Focal adhesion kinase (FAK) is overexpressed in many HCC specimens, offering a potential target for HCC treatment. However, the role of FAK in hepatocarcinogenesis remains elusive. Establishing whether FAK expression plays a role in HCC development is necessary to determine whether it is a viable therapeutic target. In this study, we generated mice with hepatocyte-specific deletion of Fak and investigated the role of Fak in an oncogenic (c-MET/β-catenin, MET/CAT)-driven HCC model. We found that deletion of Fak in hepatocytes did not affect morphology, proliferation, or apoptosis. However, Fak deficiency significantly repressed MET/CAT-induced tumor development and prolonged survival of animals with MET/CAT-induced HCC. In mouse livers and HCC cell lines, Fak was activated by MET, which induced the activation of Akt/Erk and up-regulated cyclin D1 and tumor cell proliferation. CAT enhanced MET-stimulated FAK activation and synergistically induced the activation of the AKT/ERK-cyclin D1 signaling pathway in a FAK kinase-dependent manner. In addition, FAK was required for CAT-induced cyclin D1 expression in a kinase-independent fashion. Conclusion: Fak is required for c-Met/β-catenin-driven hepatocarcinogenesis. Inhibition of FAK provides a potential strategy to treat HCC. (HEPATOLOGY 2015;61:214-226)
and cell migration. FAK has been shown to play an important role in tumorigenesis and cancer progression in several tissues, including breast, intestine, and brain. FAK was reported to be overexpressed in HCC specimens, offering a potential target to treat HCC. However, the role of FAK in hepatocarcinogenesis has not been established. Studying the role of FAK in hepatocarcinogenesis by in vivo models is critical to determine whether FAK is a suitable candidate target for treating HCC.

The oncoproteins c-MET and β-catenin play critical roles in hepatocarcinogenesis and their signaling pathways are frequently dysregulated in HCC. Coactivation of c-MET and β-catenin often occurs in HCC. Codelivery of c-MET (MET) and constitutively active β-catenin (∆N90-β-catenin, CAT) into mouse livers using the Sleeping Beauty transposon system efficiently and rapidly induces primary hepatic tumors. Therefore, this model (referred to here as MET/CAT) is useful to study the functions of genes in hepatocarcinogenesis because of its clinical relevance and efficiency.

In this study we investigated the role of Fak in MET/CAT-induced mouse models of hepatocarcinogenesis. We found that specific deletion of Fak in hepatocytes decreases HCC development and tumor proliferation in MET/CAT-induced HCC. Importantly, Fak deletion prolongs survival in animals with MET/CAT-induced HCC. Furthermore, we demonstrated that the deletion of Fak in hepatocytes significantly decreases activation of Akt, Erk, and cyclin D1 in MET/CAT-treated livers. Our data suggest that Fak is involved in the pathogenesis of HCC and inhibition of Fak may be a promising strategy to treat HCC.

**Materials and Methods**

*Mice and Treatment.* All animals received humane care according to the “Guide for the Care and Use of Laboratory Animals” http://oacu.od.nih.gov/ac_cbt/guide3.htm. The procedures for all animal experiments were approved by the Institutional Animal Care and Use Committee at Loyola University Chicago. To generate mice with hepatocyte-specific Fak-deficiency, Fak<sup>flox/flox</sup> mice (purchased from MMRRC, Cat. no. 009967) were mated to Alb-Cre mice (JAX, Cat. no. 003574). The resulting offspring Alb-Cre; Fak<sup>flox/flox</sup> mice were then mated to generate the Alb-Cre and Alb-Cre; Fak<sup>flox/flox</sup> littermates. Detailed information on genotyping of the mice can be found in the Supporting Information. The mice were housed in microisolator cages in a room illuminated from 7:00 AM to 7:00 PM (12:12-hour light-dark cycle), and allowed access to water and chow ad libitum.

For the MET/CAT-induced HCC model, 55 μg of total plasmids, encoding the Sleeping Beauty transposable (HSB2) and transposons with oncoproteins MET/CAT and gaussia luciferase (Gluc) (22.5 μg pT3-EF1 x-c-MET (human) + 22.5 μg pT3- EF1 x-∆N90-β-catenin (human) + 5 μg pT3-Gluc+ 5 μg HSB2), were injected hydrodynamically into age- and gender-matched mice. Mice were maintained on the standard diet and sacrificed after 3 days or 7 weeks. The liver weight and body weight of each mouse were measured. Some mice were injected hydrodynamically with MET (22.5 μg pT3-EF1 x-c-MET (human) + 22.5 μg pT3-EF1 x + 5 μg pT3-Gluc + 5 μg HSB2) or CAT (22.5 μg pT3-EF1 x-∆N90-β-catenin (human) + 22.5 μg pT3- EF1 x + 5 μg pT3-Gluc + 5 μg HSB2) to study activation of FAK by MET or CAT. Some mice were injected hydrodynamically with pT3 (45 μg pT3-EF1 x + 5 μg pT3-Gluc + 5 μg HSB2) to serve as controls.

**Cells and Treatment.** Huh7, HepG2, and HEP3B cells were maintained in Dulbecco’s modified Eagle’s (DMEM) high glucose medium (Thermo Scientific, Waltham, MA) supplemented with 10% fetal bovine serum (FBS), penicillin, and streptomycin (Sigma-Aldrich, St. Louis, MO) in a humidified atmosphere of 5% CO<sub>2</sub> at 37°C. Cells were plated in 6-well plates at 30-40% density 24 hours before treatment with 20 ng/mL human growth factor (HGF) (Thermo Scientific) for 15 minutes and 1 hour. Total cell lysates were prepared and used for western blotting.

For FAK shRNA experiments, cells were infected with lentiviral pLKO.1 puro particles which contain FAK or scrambled shRNA and selected with 10 μg/mL puromycin for 5 days. They were then subjected to 20 ng/mL HGF treatment for 15 minutes or 1 hour. Lentiviral pLKO.1 puro particles against human FAK shRNA (Table 1), and control scrambled shRNA (Sigma-Aldrich) were packaged with pCMV-dR8.2 dvpr (Addgene) and pCMV-VSVG (Addgene).

For β-catenin transfection experiments, Huh7 or HEP3B cells were transfected with pT3-EF1x-
Δ90Ncatenin or control pT3-EF1α plasmids by lipofectamine 2000 (Invitrogen) according to the manufacturer’s instructions. Twenty-four hours after transfection, some cells were treated with 20 ng/mL HGF for 1 hour. Total cell lysates were collected 24 hours after transfection and used in western blotting.

Isolation and Culture of Primary Mouse Hepatocytes. Hepatocytes from Alb-Cre and Alb-Cre;Fak<sup>flox</sup>/flox mice were isolated by the nonrecirculating two-step perfusion method as previously described.20 The hepatocytes were then cultured in Williams' medium E supplemented with Hepatocyte Maintenance Supplement Pack (Life Technologies, Grand Island, NY) overnight and western blotting was done to examine expression of Fak and glyceraldehyde-3-phosphate dehydrogenase (GAPDH).

Western Blotting. Western blotting was performed as previously described.21 Detailed information can be found in the Supporting Information. Primary antibodies including those for c-MET, FAK, p-FAK (Y397), p-FAK (Y576/577), GAPDH, Src, p-Src, Pyk2, p-Pyk2, p-akt (ser473), AKT, p-ERK, ERK, and cyclin D1 were purchased from Cell Signaling (Danvers, MA). β-Catenin antibody was purchased from BD Transduction Labs (San Jose, CA). p-β-Catenin (Y654) antibody was purchased from Life Technologies.

TUNEL Staining. Terminal deoxynucleotidyl transferase-mediated deoxyuridinetriphosphate nick end labeling (TUNEL) staining was performed as previously described.21 The apoptotic index was scored in at least five fields at ×400 magnification/mouse and reported as mean ± SD. Three mice were used in each group.

Immunohistochemical (IHC) and Immunofluorescence (IF) Staining. IHC and IF staining were performed as previously described.21 Detailed information can be found in the Supporting Information. Cells with positive staining were scored in at least five fields at ×400 or ×200 magnification and reported as mean ± SD. Three mice were used in each group.

Statistical Analysis. Statistical analysis was carried out using GraphPad Prism V software. Data are presented as mean ± SD. Statistical significance was calculated with a Student’s t test. P < 0.05 was considered significant. The means ± SD are shown in the figures where applicable.

Results

Deletion of Fak in Hepatocytes Does Not Affect Morphology, Histology, Proliferation, or Apoptosis in Mouse Liver. To determine the role of Fak in hepatocarcinogenesis in vivo, we first generated mice with hepatocyte-specific deletion of Fak (Alb-Cre; Fak<sup>flox</sup>/flox). Alb-cre; Fak<sup>flox</sup>/flox mice express Cre recombinase from the albumin promoter, which is specifically expressed in hepatocytes. Alb-Cre; Fak<sup>flox</sup>/flox mice are viable, fertile, and indistinguishable from wild-type (WT) mice, suggesting FAK is not required for normal liver development. We confirmed that expression of Cre recombinase in hepatocytes removes the FAK allele between two loxP sites (Fig. 1A). As hepatocytes comprise about 80% of the total liver cell population, we expected to see deletion of FAK in the majority of liver cells in Alb-Cre; Fak<sup>flox</sup>/flox mice (referred to here as Hep<sup>A<sub>Fak</sub></sup>). Western blotting results confirmed our hypothesis (Fig. 1B). We further isolated hepatocytes from Hep<sup>A<sub>Fak</sub></sup> and control Alb-Cre mice (referred to here as Hep<sup>WT</sup>) and verified complete deletion of Fak protein in the hepatocytes of Hep<sup>A<sub>Fak</sub></sup> mice (Supporting Fig. S1; Fig. 1B). There was no significant difference in morphology and histology of livers between Hep<sup>WT</sup> and Hep<sup>A<sub>Fak</sub></sup> mice (Fig. 1C,D; Fig. S2). Furthermore, Fak deficiency did not affect cell proliferation or apoptosis in mouse liver (Fig. 1E,F). These results suggest that deletion of Fak in hepatocytes does not affect mouse liver homeostasis.

Deficiency of Fak in Hepatocytes Suppresses MET/CAT-Induced HCC Development. To study the role of Fak in hepatocarcinogenesis, we hydrodynamically injected age- and gender-matched Hep<sup>WT</sup> and Hep<sup>A<sub>Fak</sub></sup> mice (Fig. S3A) with plasmids encoding the Sleeping Beauty transposase (HSB2) and transposons with oncopogenes MET/CAT.15,17 Immunohistochemical staining confirmed successful delivery of MET (recognized by an antibody specific for human c-MET) and CAT (with high expression or nuclear localization of β-catenin) in the mouse livers (Fig. S3B; Table 2). Interestingly, a majority of the hepatocytes with high MET expression coexpressed CAT (Fig. 2A, Table 2), suggesting that hydrodynamic injection equivalently delivered both plasmids into the same cells.

Mice were sacrificed 7 weeks after the injection and their livers were collected and analyzed. Intriguingly, we found that the overall tumor load in Hep<sup>A<sub>Fak</sub></sup> mice

**Results**

**Deletion of Fak in Hepatocytes Does Not Affect Morphology, Histology, Proliferation, or Apoptosis in Mouse Liver.** To determine the role of Fak in hepatocarcinogenesis in vivo, we first generated mice with hepatocyte-specific deletion of Fak (Alb-Cre; Fak<sup>flox</sup>/flox). Alb-cre; Fak<sup>flox</sup>/flox mice express Cre recombinase from the albumin promoter, which is specifically expressed in hepatocytes. Alb-Cre; Fak<sup>flox</sup>/flox mice are viable, fertile, and indistinguishable from wild-type (WT) mice, suggesting FAK is not required for normal liver development. We confirmed that expression of Cre recombinase in hepatocytes removes the FAK allele between two loxP sites (Fig. 1A). As hepatocytes comprise about 80% of the total liver cell population, we expected to see deletion of FAK in the majority of liver cells in Alb-Cre; Fak<sup>flox</sup>/flox mice (referred to here as Hep<sup>A<sub>Fak</sub></sup>). Western blotting results confirmed our hypothesis (Fig. 1B). We further isolated hepatocytes from Hep<sup>A<sub>Fak</sub></sup> and control Alb-Cre mice (referred to here as Hep<sup>WT</sup>) and verified complete deletion of Fak protein in the hepatocytes of Hep<sup>A<sub>Fak</sub></sup> mice (Supporting Fig. S1; Fig. 1B). There was no significant difference in morphology and histology of livers between Hep<sup>WT</sup> and Hep<sup>A<sub>Fak</sub></sup> mice (Fig. 1C,D; Fig. S2). Furthermore, Fak deficiency did not affect cell proliferation or apoptosis in mouse liver (Fig. 1E,F). These results suggest that deletion of Fak in hepatocytes does not affect mouse liver homeostasis.

**Deficiency of Fak in Hepatocytes Suppresses MET/CAT-Induced HCC Development.** To study the role of Fak in hepatocarcinogenesis, we hydrodynamically injected age- and gender-matched Hep<sup>WT</sup> and Hep<sup>A<sub>Fak</sub></sup> mice (Fig. S3A) with plasmids encoding the Sleeping Beauty transposase (HSB2) and transposons with oncopogenes MET/CAT.15,17 Immunohistochemical staining confirmed successful delivery of MET (recognized by an antibody specific for human c-MET) and CAT (with high expression or nuclear localization of β-catenin) in the mouse livers (Fig. S3B; Table 2). Interestingly, a majority of the hepatocytes with high MET expression coexpressed CAT (Fig. 2A, Table 2), suggesting that hydrodynamic injection equivalently delivered both plasmids into the same cells.

Mice were sacrificed 7 weeks after the injection and their livers were collected and analyzed. Intriguingly, we found that the overall tumor load in Hep<sup>A<sub>Fak</sub></sup> mice...
was significantly decreased compared with Hep\textsuperscript{WT} mice (Fig. 2B; Fig. S3C). The relative liver weight versus body weight in Hep\textsuperscript{ΔFak} mice was decreased by 1.5-fold compared to Hep\textsuperscript{WT} mice (0.16 ± 0.34 versus 0.04 ± 0.13) (Fig. 2C). The size of the tumors was also significantly decreased in the livers of Hep\textsuperscript{ΔFak} mice compared to those of Hep\textsuperscript{WT} mice (Fig. 2B,D; Fig. S3D). Immunohistochemical staining signals for alpha-fetoprotein (AFP), a common HCC marker, were significantly lower in the livers of Hep\textsuperscript{ΔFak} mice compared to those of Hep\textsuperscript{WT} mice (Fig. 2E; Fig. S3E). Importantly, the Hep\textsuperscript{WT} mice with a liver tumor burden died at the age of 60-70 days, while all of Hep\textsuperscript{ΔFak} mice were still alive at the age of 90 days.

Fig. 1. Deletion of Fak in hepatocytes does not affect morphology, histology, proliferation, or apoptosis in mouse liver. (A) Genotyping of Alb-Cre, Alb-Cre; FAK\textsuperscript{lox/lox}, and Alb-Cre; FAK\textsuperscript{lox/lox} mice. (B) Protein expression of Fak and GAPDH in whole livers and isolated hepatocytes of Alb-Cre (Hep\textsuperscript{WT}) and Alb-Cre; Fak\textsuperscript{lox/lox} (Hep\textsuperscript{ΔFak}) mice was determined by western blotting. (C) Photographs of livers from Hep\textsuperscript{WT} and Hep\textsuperscript{ΔFak} mice at 7 weeks of age. (D) Representative pictures of hematoxylin and eosin (H&E)-stained sections for (C). (E) Left, hepatic proliferation in the livers of 7-week-old Hep\textsuperscript{WT} and Hep\textsuperscript{ΔFak} mice was examined by immunohistochemistry for Ki67 protein expression. Right, quantification of Ki67 staining (n = 3). (F) Left, hepatic apoptosis in the livers of 7-week-old Hep\textsuperscript{WT} and Hep\textsuperscript{ΔFak} mice was examined by TUNEL staining. Right, quantification of TUNEL staining for (E) (n = 3).
The data indicate that deficiency of FAK in hepatocytes suppresses MET/CAT-induced HCC development and prolongs survival of animals with HCC.

Fak Deficiency in Hepatocytes Decreases Proliferation in MET/CAT-Induced HCC. Fak has been shown to regulate cell survival and proliferation. Suppression of HCC development by deletion of Fak could be due to increased apoptosis or decreased proliferation of tumor cells. To determine whether deficiency of Fak affects apoptosis in MET/CAT-induced HCC, we performed TUNEL staining in the livers from HepWT and HepΔfak mice injected with MET/CAT. We did not find significant differences in apoptosis in livers when comparing HepWT and HepΔfak mice (Fig. 3A,B). We then analyzed proliferation in the MET/CAT-injected livers from HepWT and HepΔfak mice by antigen Ki-67 (Ki67) and bromodeoxyuridine (BrdU) staining. The number of Ki67- and BrdU-positive cells was significantly decreased in tumors but not in areas without tumor in Fak-deficient livers compared to WT livers (Fig. 3C,D; Fig. S4). These results demonstrate that Fak deficiency in hepatocytes decreases cell proliferation in MET/CAT-induced HCC.

Fak Is Activated by MET but Not CAT in Mouse Liver. The kinase activity of FAK plays a critical role in its functions. Phosphorylation of FAK at

(F) Survival curves of HepWT and HepΔfak mice after of MET/CAT (n = 4).
Tyr397 can recruit and activate Src family kinases.\textsuperscript{22,26} Src activation results in phosphorylation of additional sites on FAK and leads to its full activation.\textsuperscript{27} The mutually activated FAK/Src complex then initiates multiple downstream signaling pathways.\textsuperscript{6} We therefore examined whether Fak is phosphorylated by MET/CAT. We found that phosphorylation of Fak was significantly increased in the livers from mice which were injected with MET/CAT after 7 weeks compared to livers from control mice (Fig. 4A). To determine whether Fak could be activated by MET/CAT before tumor development, phosphorylation of Fak at Tyr397 was examined in the mouse livers 3 days after hydrodynamic injection of MET/CAT. Phosphorylation of Fak was significantly increased in those livers compared to controls (Fig. 4B). Furthermore, hydrodynamic injection of MET alone, but not CAT alone, was sufficient to activate FAK in mouse liver (Fig. 4C,D). Our data indicate that overexpression of MET activates FAK in mouse livers.

Fak Deficiency in Hepatocytes Decreases Activation of Akt and Erk in MET/CAT-Induced HCC. FAK can phosphorylate and activate a number of oncoproteins which promote cell growth and proliferation, such as AKT and ERK.\textsuperscript{6,7} We reasoned that deficiency of Fak may inhibit cell proliferation and development of HCC by inactivating Akt or Erk, as it does in many other tissues.\textsuperscript{9-11} We therefore examined
the expression of p-Akt and p-Erk in MET/CAT-treated livers collected from HepWT and HepD mice. As expected, we found that the levels of both phosphorylated-Akt and -Erk were significantly increased in HepWT livers after MET/CAT-treatment. However, the levels of these two proteins were reduced in the livers of HepD mice compared to those of HepWT mice (Fig. 5A), suggesting that deletion of FAK may suppress MET/CAT-induced HCC through inhibiting Akt and Erk.

MET has been shown to activate AKT and ERK in HCC cells. We therefore assessed whether FAK mediates activation of AKT and ERK by MET. We found that MET or its ligand HGF can induce activation of Fak in mouse livers (Fig. 4C) or the liver cancer cell lines Huh7 and HepG2 (Fig. 5B; Fig. S5). Furthermore, knockdown of FAK attenuated activation of AKT and ERK by HGF in Huh7 and HepG2 cells (Fig. 5B,C). These data suggest that FAK mediates the activation of AKT and ERK induced by MET in HCC cells.

Src plays an important role in regulating the activation of AKT and ERK. We thus examined whether deletion of FAK suppresses activation of AKT and ERK through inhibiting Src activation. Interestingly, we found that phosphorylation of Src was comparable in the livers between HepFAK and HepWT mice (Fig. S6), suggesting that suppression of AKT and ERK activation caused by Fak deletion may not be caused by the inhibition of Src activation.

Combination of CAT and MET Has a Synergistic Effect on Activation of FAK in HCC Cells. Fak has been shown to be required downstream of Wnt/c-Myc signaling for Akt activation, intestinal regeneration, and tumorigenesis. We thus examined whether β-catenin activates FAK in HCC cells. We found that overexpression of CAT did not enhance the phosphorylation of FAK, Akt, or ERK in Huh7 or Hep3B cells (Fig. 6A). These data suggest that CAT may not be sufficient to activate FAK in HCC cells.

An interaction of c-MET with β-catenin has been reported in liver cells. HGF/C-MET can phosphorylate β-catenin at tyrosine 654 and induce β-catenin nuclear translocation and activation. On the other hand, activation of β-catenin can increase c-MET protein expression. Therefore, it is possible that the
combination of MET and CAT might have a synergistic effect on FAK activation. Indeed, we found that the combination of CAT and HGF or MET synergistically activates FAK in Huh7 cells (Fig. 6B) or mouse liver (Fig. 6C). Correspondingly, phosphorylation of β-catenin at tyrosine 654 was also enhanced by codeelivery of HGF or MET and CAT in Huh7 cells or mouse liver (Fig. 6B,C). These results suggest that the combination of MET and CAT has a synergistic effect on FAK activation in HCC cells.

**FAK Mediates Cyclin D1 Regulation by MET or CAT in HCC Cells.** Cyclin D1, a downstream target of the PI3K/AKT, MAPK, and Wnt/β-catenin pathways, is a key regulator of cell proliferation. Overexpression of cyclin D1 has been related to the development and progression of HCC. Cyclin D1 is increased in MET/CAT-induced tumors and has been shown to mediate MET/CAT-induced hepatocarcinogenesis. Therefore, we speculated that suppression of AKT and ERK caused by FAK deletion might decrease cyclin D1 expression. Indeed, cyclin D1 induction by MET/CAT was significantly attenuated by a deficiency of Fak in mouse livers (Fig. 7A). In addition, knockdown of FAK significantly suppressed cyclin D1 induction by HGF in Huh7 and HEPG2 cells (Fig. 7B). Furthermore, the PI3K/AKT inhibitor,

![Image](image_url)
LY294002, or the MEK/ERK inhibitor, GSK1120212, decreased cyclin D1 expression in Huh7 and HEPG2 cells (Fig. 7C; Fig. S7). These data suggest that FAK mediates cyclin D1 induction by HGF/c-MET through the AKT and ERK pathways. Finally, as cyclin D1 is a well-characterized target of activated β-catenin,\(^35\) we tested whether FAK mediates cyclin D1 induction by CAT. Knockdown of FAK abrogated the induction of cyclin D1 by CAT in HCC cells (Fig. 7D), although FAK activity and expression were not enhanced by CAT (Fig. 6A). These results suggest that a basal level of FAK is required for CAT-stimulated cyclin D1 expression (Fig. 7D), which might be independent of AKT or ERK as neither AKT nor ERK was activated by CAT (Fig. 6A).

**Fak Deficiency in Hepatocytes Does Not Result in Compensatory Expression of Pyk2 in Mouse Liver.** Pyk2 is the other member of the FAK subfamily of cytoplasmic tyrosine kinases that shares significant sequence homology and a similar structural organization with FAK.\(^36\) Several reports showed that deletion of FAK can lead to increased expression of endogenous Pyk2, which compensates for Fak functions in embryonic fibroblasts, adult endothelial cells, or mammary cancer stem cells.\(^37\) We therefore examined whether Fak deletion results in compensatory expression of Pyk2 in mouse livers. There were no significant changes in the expression of Pyk2 or p-Pyk2 in the livers between Hep\(^{Δfak}\) and Hep\(^{WT}\) mice (Fig. S8). These data suggest that Fak deficiency in hepatocytes does not lead to a compensatory expression of Pyk2.

**Discussion**

Effective therapeutic strategies are desperately needed for the treatment of HCC. c-MET and β-catenin signaling pathways are frequently dysregulated in human HCC samples.\(^14\)\(^15\)\(^40\) Coactivation of c-MET and β-catenin often occurs in HCC\(^15\) and
Fig. 7. FAK mediates cyclin D1 regulation by MET or CAT in HCC cells. (A) Cyclin D1 mRNA expression level in the livers of HepWT and HepFAK mice 7 weeks after injection of MET/CAT. (B) Protein expression of FAK, cyclin D1, and GAPDH in Huh7 and HEPG2 cells infected with scrambled shRNA or FAK shRNA#1 lentiviral particles, then treated with 20 ng/mL HGF for 15 or 60 minutes. (C) Protein expression of p-AKT, AKT, p-ERK, ERK, cyclin D1, and GAPDH in Huh7 cells treated with 10 μM LY294002 or 500 nM GSK1120212 for 24 hours. (D) Protein expression of FAK, β-catenin, cyclin D1, and GAPDH in Huh7 cells infected with scrambled shRNA, FAK shRNA#1, or FAK shRNA#2 lentiviral particles, then transfected with CAT or control plasmids. (E) A schematic model: hydrodynamic injection of MET into hepatocytes results in Fak activation. CAT does not activate FAK directly but the combination of CAT and MET has a synergistic effect on Fak activation. Fak activation regulates MET- or CAT-mediated cyclin D1 induction, acting through either Akt- and Erk-dependent or -independent pathways, thereby promoting hepatocarcinogenesis.
codelivery of MET and CAT using the Sleeping Beauty transposon system efficiently and rapidly induced HCC in mice.\textsuperscript{15,17,18} HCC development in these mice resembles the pathogenesis of human HCC, providing a useful model system to study the role of signaling pathways in HCC initiation, progression, and drug-response. In this study, we found that Fak deficiency suppresses MET/CAT-induced hepatocarcinogenesis and delays animal mortality by MET/CAT-induced HCC, suggesting that inhibition of FAK may be a promising strategy to treat HCC. It remains to be determined whether inhibition of Fak suppresses MET/CAT-induced tumor initiation, tumor progression, or both. Future studies will address this question using a hepatocyte-specific inducible Fak knockout mice.

The molecular mechanisms by which MET/CAT induces HCC are largely unknown. Our study has demonstrated that Fak deficiency in hepatocytes largely blocks HCC development induced by MET/CAT. This indicates that Fak is a key mediator of MET/CAT-induced hepatocarcinogenesis. c-MET directly interacts with the FERM domain of FAK and phosphorylates FAK in MEFs and HEK293 cells.\textsuperscript{41} Our data indicate that c-MET also phosphorylates FAK in mouse liver and HCC cells. In addition, we found that knockdown of FAK attenuates the activation of AKT and ERK, the two major targets of c-MET, with the treatment of HGF in HCC cells. Therefore, we suggest that in HCC cells c-MET might directly bind to and activate FAK, which is critical for activating AKT and ERK. We also found that cyclin D1 induction by MET/CAT is significantly attenuated by Fak deficiency in mouse liver. As cyclin D1 is a downstream target of the PI3K/AKT and MAPK pathways and plays a key role as a regulator of cell proliferation,\textsuperscript{33} these data suggest that FAK might mediate c-MET-driven tumor proliferation and development by regulating cyclin D1 through the AKT and ERK pathways.

Our results showed that CAT alone does not enhance expression of p-FAK (Y397), p-AKT, or p-ERK in mouse liver and HCC cells, suggesting that CAT does not directly phosphorylate FAK to enhance its kinase activity in liver cells. However, we found that the combination of CAT and MET has a synergistic effect on FAK activation. The underlying mechanisms remain to be determined. However, c-MET has been reported to interact with and phosphorylate β-catenin in liver cells,\textsuperscript{30,31} and we found that the combination of MET and CAT enhances phosphorylation of β-catenin at tyrosine 654. Therefore, it is possible that activation of FAK by c-Met phosphorylates β-catenin and enhances β-catenin’s nuclear translocation and function.\textsuperscript{42-44} Phosphorylated β-catenin might also facilitate c-Met activation to promote FAK activity. Thus, Met-FAK-CAT might form a feed-forward loop in Met/CAT-induced HCC. Inactivation of FAK might break such a loop and inhibit HCC. However, without c-Met, basal levels of FAK are required for CAT-induced cyclin D1 expression in HCC cells, which might be independent of its kinase activity. Interestingly, some specific Wnt targets, including glutamine synthetase, regucalcin, and axin-2, were not affected by Fak deletion in MET/CAT-induced tumors (Fig. S9). These data suggest that FAK might specifically regulate some downstream targets of β-catenin, such as cyclin D1, through both kinase-dependent (such as in Met/CAT treatment) and kinase-independent (such as in CAT-only transduction) pathways. Activated β-catenin binds to TCF4 and transcriptionally activates cyclin D1 in tumor cells.\textsuperscript{45} Future studies are needed to determine whether the kinase-dependent and -independent activities of FAK play a role in the transcriptional regulation of cyclin D1 by the β-catenin/TCF4 complex, and whether a FAK kinase-independent function is involved in HCC development.

In conclusion, our study shows that Fak plays a critical role in MET/CAT-driven hepatocarcinogenesis (Fig. 7E). Inhibition of FAK may offer an effective strategy to protect against HCC development. The normal liver function of mice with hepatocyte-specific Fak deficiency is reassuring. A number of FAK inhibitors have been developed and are being studied in phase I or phase II clinical trials for multiple solid tumors.\textsuperscript{46,47} These inhibitors might be useful for treating HCC, especially in patients showing overexpression of c-MET and activated β-catenin.

Acknowledgment: We thank Drs. Manuel Diaz, Peter Breslin, Mitchell Denning, and Tarun Patel (Loyola University Chicago) for helpful discussions and advice, Drs. Robert Wiltrout (NCI) and Xin Chen (UCSF) for providing plasmids for the MET/CAT model, and Dr. Fillippo Giancotti (SKI) for providing FAK shRNA and lentiviral packaging plasmids.

Author Contributions: N.S. performed experiments, analyzed data and wrote the article; M.A. bred mice and performed experiments; A.Z. performed experiments; J.W.Z. and J.S. provided key reagents; N.Z.L. wrote the article; S.C. analyzed pathology of mouse livers and wrote the article; W.Q. designed experiments, analyzed data, and wrote the article.
