MAXIMAL TOWERS AND ULTRAFILTER BASES
IN COMPUTABILITY THEORY

STEFFEN LEMPP, JOSEPH S. MILLER,
ANDRÉ NIES, AND MARIYA I. SOSKOVA

Abstract. The tower number $t$ and the ultrafilter number $u$ are cardinal characteristics from set theory. They are based on combinatorial properties of classes of subsets of $\omega$ and the almost inclusion relation $\subseteq^*$ between such subsets. We consider analogs of these cardinal characteristics in computability theory.

We say that a sequence $\langle G_n \rangle_{n \in \omega}$ of computable sets is a tower if $G_0 = \omega$, $G_{n+1} \subseteq^* G_n$, and $G_n \setminus G_{n+1}$ is infinite for each $n$. A tower is maximal if there is no infinite computable set contained in all $G_n$. A tower $\langle G_n \rangle_{n \in \omega}$ is an ultrafilter base if for each computable $R$, there is $n$ such that $G_n \subseteq^* R$ or $G_n \subseteq^* \overline{R}$; this property implies maximality of the tower. A sequence $\langle G_n \rangle_{n \in \omega}$ of sets can be encoded as the “columns” of a set $G \subseteq \omega$. Our analogs of $t$ and $u$ are the mass problems of sets encoding maximal towers, and of sets encoding towers that are ultrafilter bases, respectively. The relative position of a cardinal characteristic broadly corresponds to the relative computational complexity of the mass problem. We use Medvedev reducibility to formalize relative computational complexity, and thus to compare such mass problems to known ones.

We show that the mass problem of ultrafilter bases is equivalent to the mass problem of computing a function that dominates all computable functions, and hence, by Martin’s characterization, it captures highness. On the other hand, the mass problem for maximal towers is below the mass problem of computing a non-low set. We also show that some, but not all, noncomputable low sets compute maximal towers: Every noncomputable (low) c.e. set computes a maximal tower but no 1-generic $\Delta_2^0$-set does so.

We finally consider the mass problems of maximal almost disjoint, and of maximal independent families. We show that they are Medvedev equivalent to maximal towers, and to ultrafilter bases, respectively.

1. Introduction

Cardinal characteristics measure how far the set-theoretic universe deviates from satisfying the continuum hypothesis. They are natural cardinals greater than \( \aleph_0 \) and at most \( 2^{\aleph_0} \). For instance, the bounding number \( b \) is the least size of a collection of functions \( f: \omega \to \omega \) such that no single function dominates the entire collection. Related is the dominating number \( d \), the least size of a collection of functions \( f: \omega \to \omega \) such that every function is dominated by some function in the collection. Here, for functions \( f, g: \omega \to \omega \), we say that \( g \) dominates \( f \) if \( g(n) \geq f(n) \) for sufficiently large \( n \). An important program in set theory is to prove less than or equal-relations between characteristics in ZFC, and to separate them in suitable forcing extensions.

Analogs of cardinal characteristics in computability theory were first studied by Rupprecht \([14, 15]\) and further investigated by Brendle, Brooke-Taylor, Ng, and Nies \([2]\). An article by Greenberg, Kuyper, and Turetsky \([7]\), in part based on Rupprecht’s work, provides a systematic approach to the two connected settings of set theory and computability, at least for certain types of cardinal characteristics. The relevant characteristics are given by binary relations, such as the domination relation \( \leq^* \) between functions; their computability-theoretic analogs are ordered by reducibilities that measure relative computability. A well understood example of this is how the relation \( \leq^* \) gives rise to the bounding number \( b(\leq^*) \) and the dominating number \( d(\leq^*) \), and their analogs in computability, which are highness and having hyperimmune degree. A general reference in set theory is the survey paper by Blass \([1]\). The recent brief survey by Soukup \([18]\) contains a diagram displaying the ZFC inequalities between the most important characteristics in this setting, along with \( b(\leq^*) \) and \( d(\leq^*) \).

In this paper, we consider cardinal characteristics that do not fit into the framework of Rupprecht, and Greenberg et al. \([7]\). In particular, we initiate the study of the computability-theoretic analogs of the ultrafilter, tower, and independence numbers. These characteristics are defined in the setting of subsets of \( \omega \) up to almost inclusion \( \subseteq^* \); we give definitions below.

The ultrafilter number \( u \) is the least size of a subset of \( [\omega]^\omega \) with upward closure a nonprincipal ultrafilter on \( \omega \). We note that one cannot in general require here that the subset is linearly ordered by \( \subseteq^* \). Recall that an ultrafilter \( F \) on \( \omega \) is a \( P \)-point if for each partition \( \langle C_n \rangle \) of \( \omega \) such that \( C_n \notin F \) for each \( n \), there is \( A \in F \) such that \( C_n \cap A \) is finite for each \( n \). An ultrafilter with a linear base is a \( P \)-point. Shelah (see Wimmers \([19]\)) has shown that the non-existence of \( P \)-points is consistent with ZFC, so it is consistent that a version of \( u \) relying on linear bases would be undefined.

The tower number \( t \) is the minimum size of a subset of \( [\omega]^\omega \) that is linearly ordered by \( \subseteq^* \) and cannot be extended by adding a new element below all given

---

1This is less commonly, but perhaps more sensibly, called the unbounding number.
elements. To define the pseudointersection number \( p \), the requirement in the definition of towers that the sets in the class be linearly ordered under \( \subseteq^* \) is weakened to requiring that every finite subset of the class has an infinite intersection. So, trivially, \( p \leq t \). In celebrated work, Malliaris and Shelah \([12]\) showed (in ZFC) that \( p = t \) (see also \([18]\)). It is not hard to see that ZFC proves \( t \leq u \). It is consistent that \( t < u \) (see \([1]\) for both statements).

A class \( C \) of subsets of \( \omega \) is independent if any intersection of finitely many sets in \( C \) or their complements is infinite. The independence number \( i \) is the least cardinal of a maximal independent family. There has been much work recently on \( i \) in set theory, in particular, the descriptive complexity of maximal independent families, such as in Brendle, Fischer, and Khomskii \([3]\).

1.1. **Comparing the complexity of the analogs in computability.** The main setting for our analogy is given by the Boolean algebra of computable sets modulo finite differences. We consider maximal towers, the closely related maximal almost disjoint sets, and thereafter ultrafilter bases and maximal independent sets. As already demonstrated in the above-mentioned papers \([14, 15, 2, 7]\), the relative position of a cardinal characteristic tends to correspond to the relative computational complexity of the associated class of objects.

Note that the usual formal definitions of computation relative to an oracle only directly apply to functions \( f : \omega \to \omega \), and to subsets of \( \omega \) (simply called sets from now on, and identified with their characteristic functions). The complexity of other objects is studied indirectly, via names that are functions on \( \omega \) giving discrete representations of the object in question. A particular choice of names has to be made. For instance, real numbers can be named by rapidly converging Cauchy sequences of rational numbers.

The witnesses for cardinal characteristics are always uncountable. In contrast, in our setting, the analogous objects are countable. They will be considered as sequences of sets rather than unordered collections. For, a single set \( X \) can be used as a name for such a sequence of sets: Let \( X^{[n]} \) denote the “column” \( \{ u : (u, n) \in X \} \). To every set \( X \), we can associate a sequence \( \langle X_n \rangle_{n \in \omega} \) in a canonical way by setting \( X_n = X^{[n]} \). (When introducing terminology, we will sometimes ignore the difference between \( \langle X_n \rangle_{n \in \omega} \) and \( X \).) An alternate viewpoint is that a set \( X \) is a name for the unordered collection of sets in its coded sequence. Although such a name includes more information than is in the unordered family, this information is suppressed when we quantify over all names; our results can be read in this context.

With this naming system, one can now use sequences as oracles in computations. We view the combinatorial classes of sequences as mass problems. To measure their relative complexity, we compare them via Medvedev reducibility \( \leq_s \): Let \( C \) and \( D \) be sets of functions on \( \omega \), also known as mass problems. We say that \( C \) is Medvedev reducible to \( D \) and write \( C \leq_s D \) if there is a Turing functional \( \Theta \) such that \( \Theta^g \in C \) for each \( g \in D \). Less formally, we say that functions in \( D \) uniformly compute functions in \( C \). We will also refer to the weaker Muchnik reducibility: \( C \leq_w D \) if each function in \( D \) computes a function in \( C \).

With subsequent research in mind, we will set up our framework to apply to general countable Boolean algebras rather than merely the Boolean algebra of the

---

2For definiteness, we employ the usual computable Cantor pairing function \( \langle x, n \rangle \). Note that \( \langle x, n \rangle \geq x, n \). This property is useful in simplifying notation in some of the constructions below.
computable sets. Throughout, we fix a countable Boolean algebra $\mathbb{B}$ of subsets of $\omega$ closed under finite differences. Our basic objects will be sequences of sets in $\mathbb{B}$. We will obtain meaningful results already when we fix a countable Turing ideal $\mathcal{I}$ and let $\mathbb{B}$ be the sets with degree in $\mathcal{I}$. While we mainly study the case when $\mathbb{B}$ consists of the computable sets, in Section 6, we briefly consider two other cases: the $K$-trivial sets and the primitive recursive sets.

1.2. The mass problem $\mathcal{T}_\mathbb{B}$ of maximal towers.

**Definition 1.1.** We say that a sequence $\langle G_n \rangle_{n \in \omega}$ of sets in $\mathbb{B}$ is a $\mathbb{B}$-tower if $G_0 = \omega$, $G_{n+1} \subseteq^* G_n$, and $G_n \setminus G_{n+1}$ is infinite for each $n$. If $\mathbb{B}$ consists of the computable sets, we use the term tower of computable sets.

**Definition 1.2.** We say that a function $p$ is associated with a tower $G$ if $p$ is increasing and $p(n) \in \bigcap_{i \leq n} G_i$ for each $n$.

The following fact is elementary.

**Fact 1.3.** A tower $G$ uniformly computes a function $p$ associated with it.

**Proof.** Let $\Phi$ be the Turing functional such that $\Phi^G(0) = \min(G_0)$, and $\Phi^G(n+1)$ is the least number in $\bigcap_{i \leq n+1} G_i$ greater than $\Phi^G(n)$. This $\Phi$ establishes the required uniform reduction. \qed

**Definition 1.4.** Given a countable Boolean algebra $\mathbb{B}$ of sets, the mass problem $\mathcal{T}_\mathbb{B}$ is the class of sets $G$ such that $\langle G_n \rangle_{n \in \omega}$ is a $\mathbb{B}$-tower that is maximal, i.e., such that for each infinite set $R \in \mathbb{B}$, there is $n$ such that $R \setminus G_n$ is infinite.

Clearly, being maximal implies that no associated function is computable. In particular, a maximal tower is never computable. (Note that our notion of maximality only requires that the tower cannot be extended from below, in keeping with our set-theoretic analogy.)

1.3. The mass problem $\mathcal{U}_\mathbb{B}$ of ultrafilter bases. We now define the mass problem $\mathcal{U}_\mathbb{B}$ corresponding to the ultrafilter number. Since all filters of our Boolean algebras are countable, any base will compute a linearly ordered base by taking finite intersection. So we can restrict ourselves to linearly ordered bases. This is not always possible in the set theory setting, as discussed in the introduction.

**Definition 1.5.** Given a countable Boolean algebra $\mathbb{B}$ of sets, let $\mathcal{U}_\mathbb{B}$ be the class of sets $F$ such that $F$ is a $\mathbb{B}$-tower as in Definition 1.1 and for each set $R \in \mathbb{B}$, there is $n$ such that $F_n \subseteq^* R$ or $F_n \subseteq^* R$. We will call a set $F$ in $\mathcal{U}_\mathbb{B}$ a $\mathbb{B}$-ultrafilter base.

Each ultrafilter base is a maximal tower. In the cardinal setting, one has $t \leq u$. Correspondingly, since $\mathcal{U}_\mathbb{B} \subseteq \mathcal{T}_\mathbb{B}$, we trivially have $\mathcal{T}_\mathbb{B} \leq^* \mathcal{U}_\mathbb{B}$ via the identity reduction. The following indicates that for many natural Boolean algebras, ultrafilter bases necessarily have computational strength.

**Proposition 1.6.** Suppose that the degrees of sets in $\mathbb{B}$ form a Turing ideal $\mathcal{K}$. Then for each $\mathbb{B}$-ultrafilter base $F$ and associated function $p$ in the sense of Definition 1.2, the function $p$ is not dominated by a function with Turing degree in $\mathcal{K}$.

**Proof.** Assume that there is a function $f \geq p$ in $\mathcal{K}$. The conditions $n_0 = 0$ and $n_{k+1} = f(n_k) + 1$ define a sequence that is computable from some oracle in $\mathcal{K}$, and
for every $k$ we have that $[n_k, n_{k+1})$ contains an element of $\bigcap_{i \leq k} F_i$. So the set

$$E = \bigcup_{i \in \omega} [n_{2i}, n_{2i+1})$$

is in $\mathcal{K}$, and clearly $F_n \not\in^* E$ and $F_n \not\in^* E$ for each $n$. Therefore, $F$ is not a $\mathcal{B}$-ultrafilter base.

1.4. The Boolean algebra of computable sets. We finish the introduction by summarizing our results in the case that $\mathcal{B}$ is the Boolean algebra of all computable sets. By Theorem 3.1, every non-low set computes a set in $\mathcal{T}_B$, and this is uniform. This is not a characterization, however, because by Corollary 5.3, every noncomputable c.e. set computes a maximal tower. On the other hand, we know that there are noncomputable (necessarily low) sets that do not compute maximal towers; in particular, no 1-generic $\Delta^0_2$-set does so. This is because 1-generic $\Delta^0_2$-sets are index guessable by Theorem 3.4, and by Proposition 2.4, no index guessable set can compute a maximal tower. Here, an oracle $G$ is index guessable if $\emptyset'$ can find a computable index for $\varphi^G_e$ uniformly in $e$, provided that $\varphi^G_e$ is computable. We do not know whether index guessability characterizes the oracles that are unable to compute a maximal tower. It seems unlikely; index guessability appears to be stronger than necessary.

As already mentioned, in the setting of cardinal characteristics, $t < u$ is consistent with ZFC. Since non-low oracles can be computably dominated, it follows from Proposition 1.6 that there is a member of $\mathcal{T}_B$ that does not compute any member of $\mathcal{U}_B$. In other words, $\mathcal{U}_B \not\in_\omega \mathcal{T}_B$ in the case that $\mathcal{B}$ consists of the computable sets.

The separation above only uses the fact that members of $\mathcal{U}_B$ are not computably dominated; in fact, they are high. As we show in Theorems 3.6 and 3.8, $\mathcal{U}_B$ is Medvedev equivalent to the mass problem of dominating functions. In Section 4, we prove that the mass problem $\mathcal{I}_B$ of maximal independent families is also Medvedev equivalent to the mass problem of dominating functions. Thus, in the case that $\mathcal{B}$ is the Boolean algebra of computable sets, we have $\mathcal{U}_B \equiv_s \mathcal{I}_B$. Interestingly, we do not have a direct proof. Contrast this with the equivalence of $\mathcal{T}_B$ and $\mathcal{A}_B$, the mass problem of maximal almost disjoint families; this equivalence is direct and holds for an arbitrary Boolean algebra, as we will see presently.

2. Basics of the mass problems $\mathcal{T}_B$

2.1. The equivalent mass problems $\mathcal{T}_B$ and $\mathcal{A}_B$. Recall that in set theory, the almost disjointness number $\mathfrak{a}$ is the least possible size of a maximal almost disjoint (MAD) family of subsets of $\omega$. In our analogous setting, we call a sequence $\langle F_n \rangle_{n \in \omega}$ of sets in $\mathcal{B}$ almost disjoint (AD) if each $F_n$ is infinite and $F_n \cap F_k$ is finite for distinct $n$ and $k$.

**Definition 2.1.** In the context of a Boolean algebra $\mathcal{B}$ of sets, the mass problem $\mathcal{A}_B$ is the class of sets $F$ such that $\langle F_n \rangle_{n \in \omega}$ is a maximal almost disjoint (MAD) family of subsets of $\omega$. Namely, the sequence is AD, and for each infinite set $R \in \mathcal{B}$, there is $n$ such that $R \cap F_n$ is infinite.

**Fact 2.2.** $\mathcal{A}_B \leq_s \mathcal{T}_B \leq_s \mathcal{A}_B$.

**Proof.** We suppress the subscript $\mathcal{B}$. To check that $\mathcal{A} \leq_s \mathcal{T}$, given a set $G$, let $\text{Diff}(G)$ be the set $F$ such that $F_n = G_n \setminus G_{n+1}$ for each $n$. Clearly, the operator
Diff can be seen as a Turing functional. If $G$ is a maximal $\mathfrak{B}$-tower, then $F = \text{Diff}(G)$ is MAD. For, if $R \in \mathfrak{B}$ is infinite, then $R \setminus G_n$ is infinite for some $n$, and hence $R \cap F_i$ is infinite for some $i < n$.

For $\mathcal{T} \leq_s \mathcal{A}$, given a set $F$, let $G = \text{Cp}(F)$ be the set such that

$$x \in G_n \iff \forall i < n [x \notin F_n].$$

Again, Cp is a Turing functional. If $F$ is an almost disjoint family of sets from $\mathfrak{B}$, then $G$ is a $\mathfrak{B}$-tower, and if $F$ is MAD, then $G$ is a maximal tower.

Recall that a maximal tower is not computable. Hence no MAD family is computable. (This corresponds to the cardinal characteristics being uncountable.)

### 2.2. Descriptive complexity and index complexity for maximal towers.

For the rest of this section, as well as the subsequent three sections, we will mainly be interested in the case that $\mathfrak{B}$ is the Boolean algebra of all computable sets. We will omit the parameter $\mathfrak{B}$ when we name the mass problems. In the final section, we will consider other Boolean algebras.

Besides looking at the relative complexity of mass problems such as $\mathcal{T}$ and $\mathcal{U}$, one can also look at the individual complexity of their members (as sets encoding sequences). Recall that a characteristic index for a set $M$ is a number $e$ such that $\chi_M = \varphi_e$. The following two questions arise:

(1) How low in the arithmetical hierarchy can the set be located?

(2) How hard is it to find characteristic indices for the sequence members?

#### Arithmetical complexity.

**Fact 2.3.** No maximal tower $G$ is c.e., and no MAD set is co-c.e.

**Proof.** For the first statement, note that otherwise there is a computable function $p$ associated with $G$. The range of $p$ would extend the tower $G$.

For the second statement, note that the reduction $\text{Cp}$, introduced above to show that $\mathcal{T} \leq_s \mathcal{A}$, turns a co-c.e. set $F$ into a c.e. set $G$.

We will return to Question (1) in Section 5, where we show that c.e. MAD sets exist in every nonzero c.e. degree, and that some ultrafilter base is co-c.e.

**Complexity of finding characteristic indices for the sequence members.** In several constructions of towers $\langle G_n \rangle_{n \in \omega}$ below, such as in Corollary 5.3 and Theorem 5.4, the oracle $\emptyset''$ is able to compute, given $n$, a characteristic index for $G_n$. The oracle $\emptyset'$ does not suffice by the following result.

**Proposition 2.4.** Suppose that $G$ is a maximal tower. The oracle $\emptyset'$ is not able to compute, from input $n$, a characteristic index for $G_n$.

**Proof.** Assume the contrary. Then there is a computable function $f$ such that $\varphi_{\lim, f(n,n)}$ is the characteristic function of $G_n$. Let $\hat{G}$ be defined as follows. Given $n$ and $x$, compute the least $s > x$ such that $\varphi_{f(n,n),s}(x) \downarrow$. If the output is not 0, put $x$ into $\hat{G}_n$. Clearly $\hat{G}$ is computable. Since $G_n =^* \hat{G}_n$ for each $n$, $\hat{G}$ is a maximal tower, contrary to Fact 2.3, or to the earlier observation that maximal towers cannot be computable. □
3. Complexity of $T$ and of $U$

In this section, we compare our two principal mass problems, maximal towers and ultrafilter bases, to well-known benchmark mass problems: non-lowness and highness. We also define index guessability. No index guessable oracle computes a maximal tower. We show that every 1-generic $\Delta^0_2$-set is index guessable.

As we said above, we restrict ourselves to the case that $B$ is the Boolean algebra of computable sets.

3.1. Maximal towers, non-lowness, and index guessability. We now show that each non-low oracle computes a set in $T$. The result is uniform in the sense of mass problems. Let NonLow denote the class of oracles $Z$ such that $Z' \not\leq_T \emptyset'$.

**Theorem 3.1.** $T \leq_s \text{NonLow}$.

**Proof.** In the following, $x, y, z$ denote binary strings; we identify such a string $x$ with the number whose binary expansion is $1x$. For example, the string 000 is identified with 8, the number with binary representation 1000. Define a Turing functional $\Theta$ for the Medvedev reduction as follows: Set $\Theta Z = G$, where for each $n$,

$$G_n = \{x : n \leq s := |x| \wedge Z_s' | n = x | n\}.$$ 

Here $Z'$ denotes the jump of $Z$, which is computably enumerated relative to $Z$ in a standard way. Note that, for each $n$, for sufficiently large $s$, the string $Z_s' | n$ settles. So it is clear that for each $n$, we have $G_n + 1 \subseteq \ast G_n$ and $G_n \setminus G_n + 1$ is infinite. Also $G_n$ is computable.

Suppose now that $R$ is an infinite set such that $R \subseteq^* G_n$ for each $n$. Then for each $k$,

$$Z'(k) = \lim_{x \in G_n, |x| > k} x(k) = \lim_{x \in R, |x| > k} x(k),$$

and hence $Z' \leq_T R'$. So if $Z \in \text{NonLow}$, then $R$ cannot be computable, and hence $\Theta Z \in T$. \hfill $\square$

**Remark 3.2.** The proof above yields a more general result. Suppose that $K$ is a countable Turing ideal and $B$ is the Boolean algebra of sets with degree in $K$. Then $T_B \leq_s \text{NonLow}_K$, where $\text{NonLow}_K := \{Z : \forall R \in K [Z' \not\leq_T R']\}$.

We next introduce a property of oracles that we call index guessability; it implies that an oracle does not compute a maximal tower. As usual, let $\langle \Phi_e \rangle_{e \in \omega}$ be an effective list of the Turing functionals with one input, and write $\varphi_e$ for $\Phi_e^\emptyset$. Note that if $L$ is a $\Delta^0_2$-oracle, then $\emptyset''$ can compute from $e$ a characteristic index for $\Phi_e^L$ in case that the function $\Phi_e^L$ is computable. To be index guessable means that $\emptyset'$ suffices.

**Definition 3.3.** We call an oracle $L$ index guessable if $\emptyset'$ can compute from $e$ an index for $\Phi_e^L$ whenever $\Phi_e^L$ is a computable function. In other words, there is a functional $\Gamma$ such that

$$\Phi_e^L \text{ is computable} \Rightarrow \Phi_e^L = \varphi_{\Gamma(\emptyset'; e)}.$$

No assumption is made on the convergence of $\Gamma(\emptyset'; e)$ in case $\Phi_e^L$ is not a computable function.

Clearly, being index guessable is closed downward under $\leq_T$. A total function is computable if and only if its graph is computable, in a uniform way. So for index
guessability of $L$, it suffices that there is a Turing functional $\Gamma$ such that $\Gamma(\emptyset'\cdot e)$ provides an index for $\Phi^L_e$ in case it is a computable $\{0,1\}$-valued function.

Every index guessable oracle $D$ is low. To see this, for $i \in \omega$, let $B_i = \{ t : i \in D'_i \}$. If $i \in D'$ then $B_i$ is cofinite, otherwise $B_i = \emptyset$. There is a computable function $g$ such that $\Phi^D_{g(i)}$ is the characteristic function of $B_i$. To show that $D' \leq_T \emptyset'$, on input $i$, let $\emptyset'$ compute a computable index $r(i)$ for $B_i$. Now use $\emptyset'$ again to determine $\lim_k \varphi_{r(i)}(k)$, which equals $D'(i)$.

By Proposition 2.4, an index guessable oracle $D$ does not compute a maximal tower. The following provides examples of such oracles.

**Theorem 3.4.** If $L$ is $\Delta^0_2$ and 1-generic, then $L$ is index guessable.

**Proof.** Suppose that $F = \Phi^L_e$ and $F$ is a computable set. Let $S_e$ be the c.e. set of strings $\sigma$ above which there is a $\Phi_e$-splitting in the sense that

$$S_e = \{ \sigma : (\exists p)(\exists \tau_1 > \sigma)(\exists \tau_2 > \sigma) \Phi^\tau_1_e(p) \neq \Phi^{\tau_2}_e(p) \}. $$

Suppose that $S_e$ is dense along $L$. Then we claim that the set

$$C_e = \{ \tau : (\exists p) \Phi^\tau_e(p) \neq F(p) \}$$

is also dense along $L$, i.e., for every $k$, there is some $\tau \geq L \upharpoonright k$ such that $\tau \in C_e$. Indeed, let $\sigma \geq L \upharpoonright k$ be a member of $S_e$ and let $p, \tau_1$, and $\tau_2$ witness this. Let $\tau_i$ for $i = 1$ or $2$ be such that $\Phi^\tau_i_e(p) \neq F(p)$. Then $\tau_i \geq L \upharpoonright k$ is in $C_e$. The set $C_e$ is c.e. and hence $L$ meets $C_e$, contradicting our assumption that $F = \Phi^L_e$.

It follows that $S_e$ is not dense along $L$. In other words, there is some least $k_e$ such that there is no splitting of $\Phi_e$ above $L \upharpoonright k_e$. On input $e$, the oracle $\emptyset'$ can compute $k_e$ and $L \upharpoonright k_e$. This allows $\emptyset'$ to find an index for $F$, given by the following procedure: To compute $F(p)$, find the least $\tau \geq L \upharpoonright k_e$ such that $\Phi^\tau_e(p) \downarrow$ (in $|\tau|$ many steps). Such a $\tau$ exists because $\Phi^L_e(p) \downarrow$. By our choice of $k_e$, it follows that $\Phi^\tau_e(p) = \Phi^L_e(p) = F(p)$. \qed

We summarize the known implications:

1-generic $\Delta^0_2 \Rightarrow$ index guessable $\Rightarrow$ computes no maximal tower $\Rightarrow$ low.

The last arrow does not reverse by Theorem 5.1 below; the others might. In particular, we ask whether any oracle that computes no maximal tower is index guessable. This would strengthen Theorem 3.1. Note that the following potential weakening of index guessability of $L$ still implies that the oracle computes no maximal tower: For each $S \leq_T L$ such that each $S_n$ is computable, there is binary computable function $f$ such that $S_n = \varphi_{\lim_n f(n,s)}$ for each $n$.

**Aside.** We pause briefly to mention a potential connection of our topic to computational learning theory. One says that a class $S$ of computable functions is $EX$-learnable if there is a total Turing machine $M$ such that $\lim_s M(f \upharpoonright s)$ exists for each $f \in S$ and is an index for $f$. For an oracle $A$, one says that $S$ is $EX[A]$-learnable if there is an oracle machine $M$ that is total for each oracle and such that $\lim_s M^A(f \upharpoonright s)$ exists for each $f \in S$ and is an index for $f$. One calls an oracle $A$ $EX$-trivial if $EX = EX[A]$. Slaman and Solovay [16] showed that $A$ is $EX$-trivial if and only if $A$ is $\Delta^0_2$ and has 1-generic degree. This used an earlier result of Haught that the Turing degrees of the 1-generic $\Delta^0_2$-sets are closed downward.
3.2. **Ultrafilter bases and highness.** Let \( \text{Tot} = \{ e : \varphi_e \text{ is total} \} \). Let \( \text{DomFcn} \) denote the mass problem of functions \( h \) that dominate every computable function and also satisfy \( h(s) \geq s \) for all \( s \). Note that a set \( F \) is high if and only if \( \text{Tot} \leq_T F' \). To represent highness by a mass problem in the Medvedev degrees, one can equivalently choose the set of functions dominating each computable function, or the set of approximations to \( \text{Tot} \), i.e., the \( \{0, 1\} \)-valued binary functions \( f \) such that \( \lim_s f(e, s) = \text{Tot}(e) \). This follows from the next fact; we omit the standard proof.

**Fact 3.5.** \( \text{DomFcn} \) is Medvedev equivalent to the mass problem of approximations to \( \text{Tot} = \{ e : \varphi_e \text{ is total} \} \).

We show that exactly the high oracles compute ultrafilter bases, and that the reductions are uniform. By Fact 3.5, it suffices to show that \( U \equiv_s \text{DomFcn} \). We will obtain the two Medvedev reductions through separate theorems, with proofs that are unrelated.

**Theorem 3.6.** Every ultrafilter base uniformly computes a dominating function. In other words, \( U \geq_s \text{DomFcn} \).

Our proof is directly inspired by a proof of Jockusch [8, Theorem 1, (iv) \( \implies \) (i)], who showed that any family of sets containing exactly the computable sets must have high degree.

**Lemma 3.7.** There is a uniformly computable sequence \( P_0, P_1, \ldots \) of nonempty \( \Pi^0_1 \)-classes such that for every \( e \),
- if \( \varphi_e \) is total, then \( P_e \) contains a single element, and
- if \( \varphi_e \) is not total, then \( P_e \) contains only bi-immune elements.

**Proof.** Note that each Martin-Löf (or even Kurtz) random set is bi-immune: For an infinite computable set \( R \), the class of sets containing \( R \) is a \( \Pi^0_1 \)-null class and hence determines a Kurtz test. A similar fact holds for the class of sets disjoint from \( R \).

For each \( s \), let \( n_s \) be the largest number such that \( \varphi_{e,s} \) converges on \( [0, n_s) \). We build the \( \Pi^0_1 \)-class \( P_e \) in stages, where \( P_{e,s} \) is the nonempty clopen set we have before stage \( s \) of the construction. Let \( P_{e,0} = 2^\omega \).

**Stage 0.** Start constructing \( P_e \) as a nonempty \( \Pi^0_1 \)-class containing only Martin-Löf random elements.

**Stage \( s \).** If \( n_s = n_{s-1} \), continue the construction that is currently underway, which will produce a nonempty \( \Pi^0_1 \)-class of random elements.

On the other hand, if \( n_s > n_{s-1} \), fix a string \( \sigma \) such that \( |\sigma| \subseteq P_{e,s} \) and \( |\sigma| > s \). Let \( P_{e,s+1} = [\sigma] \). End the construction that we have been following and start a new construction for \( P_e \), starting at stage \( s + 1 \), as a nonempty \( \Pi^0_1 \)-subclass of \( [\sigma] \) containing only Martin-Löf random elements.

It is clear that if \( \varphi_e \) is total, then \( P_e \) will be a singleton. Otherwise, there will be a final construction of a nonempty \( \Pi^0_1 \)-class of randomness which will run without further interruption. \( \square \)

Of course, when \( P_e \) is a singleton, its lone element must be computable.

**Proof of Theorem 3.6.** For any set \( C \), let \( S_C = \{ X \in 2^\omega : C \subseteq X \} \). Note that if \( C \) is computable (or even merely c.e.), then \( S_C \) is a \( \Pi^0_1 \)-class. Let \( Q_e = \{ X : \overline{X} \in P_e \} \) be the \( \Pi^0_1 \)-class of complements of elements of \( P_e \).
Now let $F$ be an ultrafilter base. We have that

$$\varphi_e \text{ is total } \iff (\exists i)(\exists n) \left[ F_i \setminus [0, n] \text{ is a subset of some } X \in P_e \right. \left. \text{ or its complement} \right]$$

$$\iff (\exists i)(\exists n) \left[ P_e \cap S_{F_i \setminus [0, n]} \neq \emptyset \text{ or } Q_e \cap S_{F_i \setminus [0, n]} \neq \emptyset \right].$$

Even though $S_{F_i \setminus [0, n]}$ is a $\Pi^0_1$-class, we cannot hope to compute an index using $F$. However, $S_{F_i \setminus [0, n]}$ is a $\Pi^0_1[F]$-class uniformly in $i, n$. Using the fact that the nonemptiness of a $\Pi^0_1[F]$-class is a $\Pi^0_1[F]$-property, we see that $\text{Tot} = \{ e : \varphi_e \text{ is total} \}$ is $\Sigma^0_2[F]$. Note that the $\Sigma^0_2$-index does not depend on $F$. Since $\text{Tot}$ is also $\Pi^0_1$, it is $\Delta^0_2[F]$ via a fixed pair of indices, and hence Turing reducible to $F'$ via a fixed reduction. One direction of the usual proof of the (relativized) Limit Lemma now shows that we can uniformly compute an approximation to $\text{Tot}$ from $F$. Hence, from $F$ we can uniformly compute a dominating function by Fact 3.5.

**Theorem 3.8.** Every dominating function uniformly computes an ultrafilter base. In other words, $\mathcal{U} \leq^* \text{DomFcn}$.

**Proof.** Let $\langle \psi_e \rangle_{e \in \omega}$ be an effective listing of the $\{0, 1\}$-valued partial computable functions defined on an initial segment of $\omega$. Let $V_{e,k} = \{ x : \psi_e(x) = k \}$ so that $\langle (V_{e,0}, V_{e,1}) \rangle$ is an effective listing that contains all pairs of computable sets and their complements.

Let $T = \{0, 1, 2\}^{<\omega}$. Uniformly in $\alpha \in T$, we will define a set $S_\alpha$. We first explain the basic idea and then modify it to make it work. The basic idea is to start with $S_0 = \omega$ and build $S_{\alpha \setminus k} = S_\alpha \cap V_{e,k}$ for $k = 0, 1$ and $e = |\alpha|$, that is, we split $S_\alpha$ according to the listing above. Then we consider the leftmost path $g$ so that $S_g \upharpoonright e$ is infinite for each $e$. A dominating function $h$ can eventually discover each initial segment of this path and use this to compute a set $F$ such that $F_e = h S_g \upharpoonright e$ for each $e$.

The problem is that both $S_\alpha \cap V_{e,0}$ and $S_\alpha \cap V_{e,1}$ could be finite (because $e$ is not a proper index of a computable set). In this case we still need to make sure that $F_e \setminus F_{e+1}$ is infinite. So the rightmost option at level $n$ is a set $S_{\alpha \setminus 2} = S_\alpha$ that simply removes every other element from $S_\alpha$. The sets $S_{\alpha \setminus k}$ for $k \leq 1$ will be subsets of $S_\alpha$.

We now provide the details. The set $S_\alpha$ is enumerated in increasing fashion, and possibly finite. So each $S_\alpha$ is computable, but not uniformly in $\alpha$. All the sets and functions defined below can be interpreted at stages.

Let $S_{0, s} = [0, s]$. If we have defined (at stage $s$) the set $S_\alpha = \{ r_0 < \cdots < r_k \}$, let $S_\alpha$ contain the numbers of the form $r_2i$. Let $S_{\alpha \setminus 2} = S_\alpha$. Let $S_{\alpha \setminus k} = S_\alpha \cap V_{e,k}$ for $k = 0, 1$, $e = |\alpha|$. We define a uniform list of Turing functionals $\Gamma_e$ so that the sequence $\langle \Gamma_e^h(t) \rangle_{t \in \omega}$ is nondecreasing and unbounded, for each $e$ and each oracle function $h$ such that $h(s) \geq s$ for each $s$. We will let $F_e = \{ \Gamma_e^h(t) : t \in \omega \}$.

**Definition of $\Gamma_e$.** Given an oracle function $h$, we will write $a_s$ for $\Gamma_e^h(s)$. Let $a_0 = 0$. Suppose $s > 0$ and $a_{s-1}$ has been defined. Check if there is $\alpha \in T$ of length $e$ such that $|S_{\alpha \setminus h(s)}| \geq s$. If there is no such $\alpha$, let $a_s = a_{s-1}$. Otherwise, let $\alpha$ be leftmost such. If $\max S_{\alpha \setminus h(s)} > a_{s-1}$, let $a_s = \max S_{\alpha \setminus h(s)}$. Otherwise, again let $a_s = a_{s-1}$.

Note that the sequence $\{ a_s \}_{s < \omega}$ is unbounded because for the rightmost string $\alpha \in T$ of length $e$, the set $S_{\alpha \setminus t}$ consists of the numbers in $[0, t]$ divisible by $2^e$. We
may combine the functionals \( \Gamma_e \) to obtain a functional \( \Psi \) such that \( (\Psi^h)_e = F_e \) for each \( h \) with \( h(s) \geq s \) for each \( s \).

**Claim 3.9.** If \( h \in \text{DomFcn} \), then \( F = \Psi^h \in \mathcal{U} \).

To verify this, let \( g \in 2^\omega \) denote the leftmost path in \( \{0, 1, 2\}^\omega \) such that the set \( S_g \cap e \) is infinite for every \( e \). Note that \( g \) is an infinite path, because for every \( \alpha \), if the set \( S_\alpha \) is infinite then so is \( S_\alpha^{-2} \).

Fix \( e \) and let \( \alpha = g \cap e \). Let \( p(s) \) be the least stage \( t \) such that \( S_{\alpha,t} \) has at least \( s \) elements. Since \( h \) dominates the computable function \( p \), we will eventually always pick \( \alpha \) in the definition of \( a_s = \Gamma^h_t(s) \). Hence \( F_e = \ast S_\alpha \). This implies that \( F_e \) is computable and \( F_{e+1} \subseteq F_e \). Clearly, if \( S_\alpha \) is infinite, then \( S_\beta \subseteq \infty S_\alpha \) for every \( \beta > \alpha \). Thus \( F_{e+1} \subseteq \infty F_e \).

Now let \( R \) be a computable set. Pick \( e \) such that \( R = V_{e,0} \) and \( R = V_{e,1} \). If \( g(e) = 0 \), then \( S_g \cap e+1 \subseteq V_{e,0} \) and hence \( F_{e+1} \subseteq R \). Otherwise, \( S_g \cap e+1 \subseteq V_{e,1} \) and hence \( F_{e+1} \subseteq R \).

\( \square \)

4. Maximal independent families in computability

In this short section, we determine the complexity of the computability-theoretic analog of the independence number \( i \) for the Boolean algebra of computable sets. It turns out that in the context of the computable sets, maximal independent families behave in a way similar to ultrafilter bases.

Given a sequence \( (F_n)_{n \in \omega} \), for each binary string \( \sigma \) we write

\[
F_\sigma = \bigcap_{\sigma(i) = 1} F_i \cap \bigcap_{\sigma(i) = 0} \overline{F}_i.
\]

We call (a set \( F \) encoding) such a sequence independent if each set \( F_\sigma \) is infinite.

**Definition 4.1.** Given a Boolean algebra of sets \( \mathcal{B} \), the mass problem \( \mathcal{I}_\mathcal{B} \) is the class of sets \( F \) such that \( (F_n)_{n \in \omega} \) is a family that is maximal independent, namely, it is independent, and for each set \( R \in \mathcal{B} \), there is \( \sigma \) such that \( F_\sigma \subseteq R \) or \( F_\sigma \subseteq \overline{R} \).

In the following, we let \( \mathcal{B} \) be the Boolean algebra of computable sets, and we drop the parameter \( \mathcal{B} \) as usual. An easy modification of the proof of Theorem 3.6 yields the following

**Theorem 4.2.** Every maximal independent family \( F \) uniformly computes a dominating function. In other words, \( \mathcal{I} \geq_s \text{DomFcn} \).

*Proof.* Define the \( \Pi^1_1 \)-classes \( P_e \) as in Lemma 3.7. As before let \( Q_e = \{X \colon \overline{X} \in P_e \} \) be the \( \Pi^0_1 \)-class of complements of elements of \( P_e \). Recall that for any set \( C \), we let \( S_C = \{X \in 2^\omega \colon C \subseteq X \} \). Now we have that

\[
\varphi_e \text{ is total } \iff (\exists \sigma)(\exists n) [F_\sigma \setminus [0, n] \text{ is a subset of some } X \in P_e \text{ or its complement}]
\]

\[
\iff (\exists \sigma)(\exists n) [P_e \cap S_{F_\sigma \setminus [0, n]} \neq \emptyset \text{ or } Q_e \cap S_{F_\sigma \setminus [0, n]} \neq \emptyset]
\]

As before, this shows that from \( F \) one can uniformly compute a dominating function. \( \square \)

---

3Here, \( A \subseteq_b B \) means that \( A \subseteq B \) and \( B \setminus A \) is infinite. We define \( \subseteq_{\text{\scriptsize{\infty}}} \) similarly.
Theorem 4.3. Every dominating function \( h \) uniformly computes a maximal independent family. In other words, \( \mathcal{I} \preceq \text{DomFcn} \).

In fact, we will prove that a dominating function \( h \) uniformly computes a set \( F \) such that the \( =^* \)-equivalence classes of the sets \( F_e \) freely generate the Boolean algebra of computable sets modulo finite sets.

Proof. As in the proof of Theorem 3.8, let \( \langle \psi_e \rangle_{e \in \omega} \) be an effective listing of the \( \{0,1\} \)-valued partial computable functions defined on an initial segment of \( \omega \), and let \( V_{e,k} = \{ x : \psi_e(x) = k \} \) for \( k = 0, 1 \).

In Phase \( e \) of the construction, we will define a computable set \( F_e \) such that \( F_e = \Theta^h_e \) for a Turing functional \( \Theta_e \) determined uniformly in \( e \). Suppose we have defined \( \Theta_i \) for \( i < e \), and thereby the sets \( F_i \) defined in (1), where \( \sigma \) is a string of length \( e \).

The idea for building \( F_e \) is to try to follow \( V_{e,0} \) while maintaining independence from the previous sets. We apply this strategy separately on each \( F_i \). Using \( h \) as an oracle we compute recursively an increasing sequence \( \langle r^e_n \rangle_{n \in \omega} \). We carry out the attempts on intervals \( [r^e_n, r^e_{n+1}] \). If \( V_{e,0} \) appears to split \( F_e \) on the current interval, then we follow it; otherwise, we merely make sure that \( F_e \) remains independent from \( F_r \) on the interval by putting one number in and leaving another one out. To decide which case holds, we consult the dominating function.

We now provide the details for Phase \( e \). As \( e \) is fixed, we drop the superscripts \( e \). By \( \sigma \) we will always denote a string of length \( e \). Let \( r_0 = 0 \). If \( r_n \) has been defined, let \( r_{n+1} > r_n \) be the least number \( r \) such that for each \( \sigma \)

1. \( |[r_n, r) \cap F_\sigma| \geq 2 \), and
2. if there are \( u, w \in \text{dom}(\psi_e, h(r_n)) \cap F_\sigma \) with \( r_n \leq u < w \) such that \( \psi_e(u) = 1 \) and \( \psi_e(w) = 0 \), then \( r > w \) for the least such \( w \).

We define \( F_e(x) = \Theta^h_e(x) \) for \( x \in [r_n, r_{n+1}] \) as follows. For each \( \sigma \),

- if condition (b) holds and \( \psi_e \) is defined on \( [r_n, r_{n+1}] \), then let \( F_e(x) = \psi_e(x) \);
- otherwise, if \( x = \min([r_n, r_{n+1}) \cap F_\sigma) \), let \( F_e(x) = 1 \), else let \( F_e(x) = 0 \).

Verification. By induction on \( e \), one verifies that \( F_\sigma \) is infinite for each \( \sigma \) with \( |\sigma| = e \), and that the sequence \( \langle r^e_n \rangle_{n \in \omega} \) defined in Phase \( e \) of the construction is infinite. Thus \( \Theta^h_e \) is total for each function \( h \). So \( F \preceq_T h \) where \( F_e = \Theta^h_e \), and \( F \) is an independent family.

Claim 4.4. Each set \( F_e \) is computable.

We verify this by induction on \( e \). Suppose it holds for each \( i < e \). So \( F_i \) is computable for \( |\sigma| = e \).

First assume that \( \psi_e \) is partial. Then for sufficiently large \( n \), condition (b) does not apply, and so the sequence \( \langle r^e_n \rangle_{n \in \omega} \) and hence \( F_e \) are computable.

Now assume that \( \psi_e \) is total. Let

\[ D_e = \{ \sigma : |\sigma| = e \land |F_\sigma \cap V_{e,0}| = |F_\sigma \cap V_{e,1}| = \infty \}. \]

Define a function \( p \) by letting \( p(m) \) be the least stage \( s \) such that for each \( \sigma \notin D_e \), condition (a) holds with \( r_n = m \) and \( r = s \), and for each \( \sigma \in D_e \), there are \( u, w \in \text{dom}(\psi_e, s) \) such that \( m \leq u < w \) as in condition (b). (Let \( p(m) = 0 \) if \( m \) is not of the form \( r_n \).) Since \( F_e \) is computable for each \( \sigma \) of length \( e \), the function \( p \) is computable. Since \( h \) dominates \( p \), for sufficiently large \( n \), we will define \( r_{n+1} \) by checking \( \psi_e \) at a stage \( h(r_n) \geq p(r_n) \); since we chose the witnesses minimal, \( r_{n+1} \).
is determined by stage $p(r_n)$. So we might as well check $\psi_e$ at that stage and do not need $h$. Hence the sequence $\langle r_n \rangle_{n \in \omega}$ and therefore $F_e$ are computable.

Claim 4.5. Suppose that $\psi_e$ is total. Then for each string $\tau = \sigma \alpha$ of length $e + 1$, $F_\tau \subseteq^* V_{e,0}$ or $F_\tau \cap V_{e,0} =^* \emptyset$.

If $\sigma \not\in D_e$, then this is immediate since $F_\sigma \subseteq^* V_{e,i}$ for some $i$. Otherwise, Phase $e$ of the construction ensures that $F_{\sigma^0} =^* F_\sigma \cap V_{e,0}$.

By the last claim, the $=^*$-equivalence classes of the $F_e$ freely generate the Boolean algebra of the computable sets modulo finite sets. In particular, $F$ is a maximal independent family. □

As mentioned in the introduction, we do not know at present whether there is a “natural” Medvedev equivalence between the two mass problems $U$ and $I$ as is the case for $A$ and $T$. This would require direct proofs avoiding the detour via the mass problem of dominating functions. For what it is worth, the cardinal characteristics $u$ and $i$ are incomparable (i.e., ZFC cannot determine their order).

5. The co-computably enumerable case

Recall from Fact 2.3 that no maximal tower, and in particular no ultrafilter base, can be computably enumerable. In contrast, in this section we will see that even ultrafilter bases can have computably enumerable complement. As in the previous sections, we are restricting our attention to the Boolean algebra of all computable sets.

Recall that a cofinite c.e. set $A$ is called simple if it meets every infinite c.e. (or, equivalently, computable) set; $A$ is called $r$-maximal if $\overline{A} \subseteq^* \overline{R}$ or $\overline{A} \subseteq^* R$ for each computable set $R$. Each $r$-maximal set is simple. For more background, see, e.g., Soare [17].

5.1. Computably enumerable MAD sets, and co-c.e. towers. We will show that if $A$ is a noncomputable c.e. set, then there is a co-c.e. maximal tower $G \leq_T A$. Given that it is more standard to build c.e. rather than co-c.e. sets, it will be convenient to first build a c.e. MAD set $F \leq_T A$ and then use the Medvedev reduction in Fact 2.2 to get a co-c.e. maximal tower. We employ a priority construction with requirements that act only finitely often.

Theorem 5.1. For each noncomputable c.e. set $A$, there is a MAD c.e. set $F \leq_T A$.

Proof. The construction is akin to Post’s construction of a simple set. In particular, it is compatible with permitting.

Let $\langle M_e \rangle_{e \in \omega}$ be a uniformly c.e. sequence of sets such that $M_{2e} = W_e$ and $M_{2e+1} = \omega$ for each $e$. We will build an auxiliary c.e. set $H \leq_T A$ and let the c.e. set $F \leq_T A$ be defined by $F[e] = H[2e] \cup H[2e+1]$. The purpose of the sets $M_{2e+1}$ is to make the sets $H[2e+1]$, and hence the sets $F[e]$, infinite. The construction also ensures that $H$, and hence $F$, is AD, and that $\bigcup_{n} H[n]$ is cofinite.

As usual, we will write $H_e$ for $H[e]$. We provide a stage-by-stage construction to meet the requirements

$$P_n: M_e \setminus \bigcup_{i < n} H_i \text{ infinite} \Rightarrow |H_e \cap M_e| \geq k,$$

where $n = (e, k)$. (Note that the union is over all $i$ such that $i < n$, not $i < e$.) At stage $s$, we say that $P_n$ is permanently satisfied if $|H_{e,s} \cap M_{e,s}| \geq k$.
Construction.
Stage $s > 0$. See if there is $n < s$ such that $P_n$ is not permanently satisfied, and, where $n = \langle e, k \rangle$, there is $x \in M_{e,s} \setminus \bigcup_{i<n} H_{i,s}$ such that
\[
x > \max(H_{e,s-1}), \ x \geq 2n, \text{ and } A_s \upharpoonright x \neq A_{s-1} \upharpoonright x.
\]
If so, choose $n$ least, and put $\langle x, e \rangle$ into $H$ (i.e., put $x$ into $H_e$).

Verification. Each $H_e$ is enumerated in increasing fashion and hence computable. Each $P_n$ is active at most once. This ensures that $\bigcup_e H_e$ is coinfinite: For each $N$, if $x < 2N$ enters this union, then this is due to the action of a requirement $P_n$ with $n < N$, so there are at most $N$ many such $x$.

To see that a requirement $P_n$ for $n = \langle e, k \rangle$ is met, suppose that its hypothesis holds. Then there are potentially infinitely many candidates $x$ that can go into $H_e$. Since $A$ is noncomputable, one of them will be permitted.

Now, by the choice of $M_{2e+1}$ and the fact that $\bigcup_e H_e$ is coinfinite, each $H_{2e+1}$, and hence each $F_e$, is infinite. By construction, for $e < m$, we have $|H_e \cap H_m| \leq m$. So the family described by $H$, and therefore also the one described by $F$, is almost disjoint.

To show that $F$ is MAD, it suffices to verify that if $M_e$ is infinite then $M_e \cap F_p$ is infinite for some $p$. If all the $P_{e,k}$ are permanently satisfied during the construction, we let $p = e$. Otherwise, we let $k$ be least such that $P_n$ is never permanently satisfied where $n = \langle e, k \rangle$. Then its hypothesis fails, so $M_e \subseteq^* \bigcup_{i<n} H_i$. □

Since an index guessable set computes no MAD set by Proposition 2.4, we obtain the following

**Corollary 5.2.** No noncomputable, c.e. set $L$ is index guessable.

Downey and Nies have given a direct proof of this fact (see [6]).

**Corollary 5.3.** For each noncomputable c.e. set $A$, there is a co-c.e. set $G \leq_T A$ such that $G \in T$, i.e., $\langle G_n \rangle_{n \in \omega}$ is a maximal tower.

**Proof.** Let $F$ be the MAD set obtained above. Recall the Turing reduction $C_p$ showing that $T \leq_s A$ in Fact 2.2. The set $G = C_p(F)$, given by
\[
x \in G_n \iff \forall i < n \ [x \notin F_n]
\]
is as required. □

### 5.2. Co-c.e. ultrafilter bases.

**Theorem 5.4.** There is a co-c.e. ultrafilter base $F$.

**Proof.** We adapt the construction from the proof of the main result in [11], which states that there is an $r$-maximal set $A$ such that the index set $Cof_A = \{ e : W_e \cup A =^* \omega \}$ is $\Sigma^0_3$-complete. Both the original and the adapted version make use of the fact that we are given a c.e. index for a computable set and also one for its complement (see the pairs $(V_{e,0}, V_{e,1})$ below). Our proof can also be viewed as a variation on the proof of Theorem 3.8 in the setting of co-c.e. sets. We remark that by standard methods, one can extend the present construction to include permitting below a given high c.e. set.

We build a co-c.e. tower $F$ by providing uniformly co-c.e. sets $F_e$ for $e \in \omega$ that form a descending sequence with $F_e \supseteq F_{e+1}$. We achieve the latter condition by
agreeing that whenever we remove \( x \) from \( F_e \) at a stage \( s \), we also remove it from all \( F_i \) for \( i > e \). Furthermore, no element is ever removed from \( F_0 \), so \( F_0 = \omega \).

Let \( \langle (V_{e,0}, V_{e,1}) \rangle_{e \in \omega} \) be an effective listing of all pairs of disjoint c.e. sets as defined in the proof of Theorem 3.8. The construction will ensure that the following requirements are met:

\[
M_e: F_e \setminus F_{e+1} \text{ is infinite},
\]

\[
P_e: V_{e,0} \cup V_{e,1} = \omega \Rightarrow F_{e+1} \subseteq^* V_{e,0} \lor F_{e+1} \subseteq^* V_{e,1}.
\]

This suffices to establish that \( F \) is an ultrafilter base.

The tree of strategies is \( T = \{0, 1, 2\}^{<\infty} \). Each string \( \alpha \in T \) of length \( e \) is tied to \( M_e \) and also to \( P_e \). We write \( M_e \) and \( \alpha: P_e \) to indicate that we view \( \alpha \) as a strategy of the respective type.

**Streaming.** For each string \( \alpha \in T \) with \( |\alpha| = e \), at each stage of the construction, we have a set \( S_\alpha \), thought of as a stream of numbers used by \( \alpha \). Each time \( \alpha \) is initialized, \( S_\alpha \) is removed from \( F_{e+1} \), and \( S_\alpha \) is reset to be empty. Also, \( S_\alpha \) is enlarged only at stages at which \( \alpha \) appears to be on the true path. We will verify the following properties:

\begin{enumerate}
  \item \( S_0 = \omega \);
  \item if \( \alpha \) is not the empty node, then \( S_\alpha \) is a subset of \( S_\alpha^- \) (where \( \alpha^- \) is the immediate predecessor of \( \alpha \));
  \item at every stage, \( S_\gamma \cap S_\beta = \emptyset \) for incomparable strings \( \gamma \) and \( \beta \);
  \item \( x \) is in \( F_{e+1} \) at the time a number \( x \) first enters \( S_\alpha \);
  \item if \( \alpha \) is along the true path of the construction, then \( S_\alpha \) is an infinite computable set.
\end{enumerate}

Note that \( S_\alpha \) is d.c.e. uniformly in \( \alpha \). The set \( S_\alpha \) is finite if \( \alpha \) is to the left of the true path of the construction; \( S_\alpha \) is an infinite computable set if \( \alpha \) is along the true path; and \( S_\alpha \) is empty if \( \alpha \) is to the right of the true path.

The **intuitive strategy** \( \alpha: P_e \): Only strategies associated with a string of length \( \leq e \) can remove numbers from \( F_{e+1} \). A strategy \( \alpha: P_e \) thins out \( S_\alpha \) by removing some of its elements from \( F_{e+1} \). It regards the set of remaining numbers as its private version of \( F_{e+1} \). It has to make sure that no strategies \( \beta \) to its right remove numbers from \( F_{e+1} \) that it wants to keep. On the other hand, it can only process a number \( x \) once it knows whether \( x \) is in \( V_{e,0} \) or \( V_{e,1} \). The solution to this conflict is that \( \alpha \) reserves a number \( x \) from the stream \( S_\alpha \), which by initialization withholds it from any action of such a \( \beta \). It then waits until all numbers \( \leq x \) are in \( V_{e,0} \cup V_{e,1} \). If that never happens for some reserved \( x \), then \( \alpha \) is satisfied finitarily with eventual outcome 2. Otherwise, it will eventually process \( x \): If \( x \in V_{e,0} \), it continues its attempt to build \( F_{e+1} \) inside \( V_{e,0} \); else it continues to build \( F_{e+1} \) inside \( V_{e,1} \). It takes outcome 0 or 1, respectively, according to which case applies. Each time the apparent outcome is 0, the content of the output stream based on the assumption that the true outcome is 1 is removed from \( F_{e+1} \). So if 0 is the true outcome, then indeed \( F_{e+1} \subseteq^* V_{e,0} \).

The **intuitive strategy** \( \alpha: M_e \) simply removes every other element of \( S_\alpha \) from \( F_{e+1} \). Then \( \alpha: M_e \) actually only works with the stream of remaining numbers. There is no further interaction between the two types of strategies. (Note here that making \( F_{e+1} \) smaller is to the advantage of \( P_\alpha \).) Recall that if \( \alpha \) is initialized, \( S_\alpha \) is removed from \( F_{e+1} \), and \( S_\alpha \) is reset to be empty.
Construction.

Stage 0. Let $\delta_0$ be the empty string. Let $F_e = \omega$ for each $e$. Initialize all strategies.

Stage $s > 0$. Let $S_{\emptyset,s} = [0,s)$. Stage $s$ consists of substages $e = 0, \ldots, s-1$, during which we inductively define $\delta_s$, a string of length $s$.

Substage $e$. We suppose that $\alpha = \delta_s | e$ and $S_\alpha$ have been defined.

The strategy $\alpha : M_e$ acts as follows. If at the current stage $S_\alpha = \{r_0 < \cdots < r_k\}$ and $r_k$ is new in $S_\alpha$, it puts $r_k$ into $\tilde{S}_\alpha$ if and only if $k$ is even; otherwise, $r_k$ is removed from $F_{e+1}$.

The strategy $\alpha : P_e$ picks the first applicable case below.

Case 1: Each reserved number of $\alpha$ has been processed: If there is a number $x$ from $\tilde{S}_\alpha$ greater than $\alpha$’s last reserved number (if any) and greater than the last stage $\alpha$ was initialized, pick $x$ least and reserve it. Note that $x < s$ since by definition $S_{\emptyset,s} = [0,s)$. Initialize $\alpha^2$, and let $\alpha^2$ be eligible to act next. Note that if Case 1 does not apply then $\alpha$ has a unique reserved, but unprocessed number $x$.

Case 2: $[0,x] \subseteq V_{e,0} \cup V_{e,1}$ and $x \in V_{e,0}$: Let $t$ be the greatest stage $\leq s$ at which $\alpha$ was initialized. Add $x$ to $S_\alpha \cap 0$ and remove from $F_{e+1}$ all numbers in the interval $(t,x)$ that are not in $S_\alpha \cap 0$. Declare that $\alpha$ has processed $x$. Let $\alpha^0$ be eligible to act next.

Case 3: $[0,x] \subseteq V_{e,0} \cup V_{e,1}$ and $x \in V_{e,1}$: Let $t$ be the greatest stage $\leq s$ at which $\alpha$ was initialized or $\alpha^0$ was eligible to act. Add $x$ to $S_\alpha \cap 1$ and remove from $F_{e+1}$ all numbers in the interval $(t,x)$ that are not in $S_\alpha \cap 1$. Declare that $\alpha$ has processed $x$. Let $\alpha^1$ be eligible to act next.

Case 4: Otherwise, that is, $[0,x] \not\subseteq V_{e,0} \cup V_{e,1}$: Let $t$ be the greatest stage $\leq s$ at which $\alpha$ was initialized, or $\alpha^0$ or $\alpha^1$ was eligible to act. Let $S_{\alpha^2} = \tilde{S}_\alpha \cap (t,s)$. Let $\alpha^2$ be eligible to act.

We define $\delta_s(e) = i$ where $\alpha^i$, $0 \leq i \leq 2$, has been declared eligible to act next. If $e + 1 < s$, then carry out the next substage. Else initialize all the strategies $\beta$ such that $\delta_s <_L \beta$ and end stage $s$.

Verification. By construction and our convention above, $F_e$ is co-c.e., and $F_e \geq F_{e+1}$ for each $e$.

Let $g \in 2^\omega$ denote the true path, namely, the leftmost path in $\{0,1,2\}^\omega$ such that $\forall e \exists s | g \upharpoonright e \preceq \delta_s$. In the following, given $e$, let $\alpha = g \upharpoonright e$, and let $s_\alpha$ be the largest stage $s$ such that $\alpha$ is initialized at stage $s$. Note that $s_\alpha$ exists: The only concern would be that $\alpha$ has the form $\alpha^2$ and we are at substage $\left\lfloor \alpha \right\rfloor$ in Case 1; however, $\alpha$ can only be initialized once in that way unless $\delta_e <_L \alpha$ at a later stage $r$, namely, when the number $\alpha$ has reserved is processed.

We verify a number of claims.

Claim 5.5. The “streaming properties” (1)-(5) hold.

(1) and (2) hold by construction.

(3) Assume this fails for incomparable $\gamma$ and $\beta$, so $x \in S_\gamma \cap S_\beta$ at stage $s$. We may as well assume that $\gamma = \alpha^i \beta$ and $\beta = \alpha^k$ where $i < k$. By construction, $k \leq 1$ is not possible, so $k = 2$. Since $x \in S_\gamma \cap \beta$ and $i < 1$, $x$ was reserved by $\alpha$ at some stage $t \leq s$. So $x$ can never enter $S_{\alpha^2}$ by the initialization of $\alpha^2$ when $x$ was reserved.
(4) is true by construction.

(5) holds inductively, by the definition of the true path and because $S_\alpha$ is enumerated in increasing fashion at stages $\geq s_\alpha$.

**Claim 5.6.** $F_e =^* S_\alpha$.

The claim is verified by induction on $e$. We show that for all $x > s_\alpha$ we have $x \in F_e$ if and only if $x \in S_\alpha$. It holds for $e = 0$ because $F_0 = S_\emptyset = \omega$. For the inductive step, let $\gamma = g \restriction (e + 1)$.

First, we verify that $F_{e+1} \cap (s_\gamma, \infty) \subseteq S_\gamma$. Suppose that $x > s_\gamma$ and $x \in F_{e+1}$. Then $x \in F_e$ and $x > s_\alpha$, so by the inductive hypothesis $x \in S_\alpha$. By construction, any element $x$ that is not promoted to $S_\gamma$ is also removed from $F_{e+1}$ unless $x$ is the last element $\alpha$ reserves. However, if $x$ is the last reserved element, then necessarily $\gamma = \alpha^2$ and this strategy is initialized when this element is reserved, so $x < s_\gamma$ contrary to our assumption.

Next, we verify that $S_\alpha \cap (s_\gamma, \infty) \subseteq F_{e+1}$. Suppose that $x \in S_\alpha$ and $x > s_\gamma$. Then $x \in S_\alpha$, so by the inductive hypothesis $x \in F_e$. At a stage $s \geq s_\gamma$, an element $x$ of $S_\alpha$ cannot be removed from $F_{e+1}$ by a strategy $\beta >_L \alpha$ because $S_\beta \cap S_\alpha = \emptyset$ by (3) as verified above and since $\beta$ can only remove elements from $S_\beta$. So $x$ can only be removed by $\alpha: M_e$ or $\alpha: P_e$.

If $\alpha: M_e$ removes $x$ from $F_{e+1}$, then $x \not\in \widetilde{S}_\alpha$, which contradicts that $x \in S_\gamma$. So, by construction, the only way $x$ can be removed from $F_{e+1}$ is by the strategy $\alpha: P_e$, but since $x > s_\gamma$ this would mean that $x$ is not promoted to $S_\gamma$ either contrary to our assumption.

**Claim 5.7.** Each requirement $M_e$ is met, namely, $F_e \setminus F_{e+1}$ is infinite.

To see this, recall that $\alpha = g \restriction e$. By the foregoing claim, the action of $\alpha: M_e$ removes infinitely many elements of $S_\alpha \subseteq F_e$ from $F_{e+1}$.

**Claim 5.8.** Each requirement $P_e$ is met.

Suppose the hypothesis of $P_e$ holds. Then every number that $\alpha$ reserves is eventually processed. So either $g(e) = 0$, in which case $F_{e+1} =^* V_{e,0}$ by Claim 5.6, or $g(e) = 1$, in which case $F_{e+1} =^* V_{e,1}$, also by Claim 5.6. \qed

6. **Ultrafilter bases for other Boolean algebras**

As mentioned, we have set up our framework to apply to general countable Boolean algebras rather than merely the Boolean algebra of the computable sets mainly with subsequent research in mind. In this last section of our paper, we provide two results in the setting of other Boolean algebras of sets.

Recall that $K(x)$ denotes the prefix-free complexity of a string $x$, and that a set $A \subseteq \omega$ is $K$-trivial if $\exists c \forall n K(A \restriction n) \leq K(0^n) + c$. For more background on $K$-trivial sets, see, e.g., Nies [13, Ch. 5] or Downey and Hirschfeldt [5, Ch. 11]. Note that by combining results of various authors, the $K$-trivial degrees form a Turing ideal in the $\Delta^0_2$-degrees (see, e.g., Nies [13, Sections 5.2, 5.4]). Thus the $K$-trivial sets form a Boolean algebra.

**Theorem 6.1.** There is a $\Delta^0_2$-ultrafilter base for the Boolean algebra of the $K$-trivial sets.
Proof. Kučera and Slaman [10] noted that there is a $\Delta^0_2$-function $h$ that dominates all functions that are partial computable in some $K$-trivial set. We use $h$ in a variation of the proof of Theorem 3.8.

Let $(V_{r,0}, V_{r,1})_{r \in \omega}$ be a uniform listing of the $K$-trivials and their complements given by wtt-reductions to $\emptyset'$; such a listing exists by Downey, Hirschfeldt, Nies, and Stephan [4] (see also [13, Theorem 5.3.28]). Let $T = \{0, 1\}^\omega$.

For each $\alpha \in T$, we define a (possibly finite) $K$-trivial set $S_\alpha$. Let $S_\emptyset = \omega$. Suppose we have defined the set $S_\alpha = \{r_0 < r_1 < \cdots\}$. Let $\tilde{S}_\alpha$ contain the numbers of the form $r_2l$. Let $S_{\alpha \cdot k} = \tilde{S}_\alpha \cap V_{r,k}$ for $e = |\alpha|$ and $k = 0, 1$. Note that all these sets are $K$-trivial.

Uniformly recursively in $\emptyset'$, we build sets $F_e$, given by nondecreasing unbounded sequences of numbers $a_0^e \leq a_1^e \leq \cdots$. Suppose we have defined $a_k^e$. Let $\alpha \in T$ be the lefmost string of length $e$ such that $S_\alpha$ has at least $k + 1$ elements less than $h(k)$. If $\alpha$ exists, let $a_k^\alpha$ be the $k$-th element of $S_\alpha$, unless this is less than $a_k^e$, in which case we let $a_k^\alpha = a_k^e$.

Let $g \in 2^\omega$ be the leftmost path in $\{0, 1\}^\omega$ such that for every $e$, the set $S_g \upharpoonright e$ is infinite. Fix $e$ and let $\alpha = g \upharpoonright e$. Let $p(k)$ be the $(k + 1)$-st element of $S_\alpha$. Since $h$ dominates the function $p$, eventually in the definition of $F_e$ we will always pick $\alpha$. Hence $F_e = S_\alpha$. In particular, $F_e$ is $K$-trivial. Also, the sequences $\langle a_k^e \rangle_{k \in \omega}$ are unbounded for each $e$, so $F$ is $\Delta^0_3$. Clearly, if $S_\alpha$ is infinite then $S_\alpha \supset^{\omega \omega} S_\beta$ for $\alpha < \beta$. So $F_{e+1} \subseteq F_e$.

To verify that $F$ is an ultrafilter base for the $K$-trivials, let $R$ be a $K$-trivial set. Pick $e$ such that $R = V_{e,0}$ and $\overline{R} = V_{e,1}$. If $g(e) = 0$ then $S_g \upharpoonright e+1 \subseteq V_{e,0}$, and hence $F_{e+1} \subseteq R$. Otherwise $S_g \upharpoonright e+1 \subseteq V_{e,1}$, and hence $F_{e+1} \subseteq \overline{R}$.\hfill \Box

Remark 6.2. Any ultrafilter base for the $K$-trivials must have high degree. We can see this by modifying the proof of Theorem 3.6: Every Martin-Löf random set $X$ is Martin-Löf random relative to every $K$-trivial (i.e., $K$-trivial sets are low for ML-randomness). Hence neither $X$ nor $\overline{X}$ contains an infinite $K$-trivial subset.

Finally, we consider the Boolean algebra of primitive recursive sets. One says that an oracle $L$ is of PA degree if it computes a completion of Peano arithmetic. Recall that $L$ is of PA degree if and only if it computes a separating set for each disjoint pair of c.e. sets.

Theorem 6.3. An oracle $C$ computes an ultrafilter base for the primitive recursive sets if and only if $C'$ is of PA degree relative to $\emptyset'$.

Proof. We modify the proof of Jockusch and Stephan [9, Theorem 2.1]. They call a set $S \subseteq \omega$ $p$-cohesive if $S$ is cohesive for the primitive recursive sets. Their theorem states that $S$ is $p$-cohesive if and only if $S'$ is of PA degree relative to $\emptyset'$.

$\Rightarrow$: Suppose that $C$ computes an ultrafilter base $F$ for the primitive recursive sets. Let $g \leq_T F$ be a function associated with $F$ as in Definition 1.2. Then the range $S$ of $g$ is $p$-cohesive. Hence $S'$ and therefore $C'$ is of PA relative to $\emptyset'$ by one implication of [9, Theorem 2.1].

$\Leftarrow$: We modify the proof of the other implication of [9, Theorem 2.1]. Let $\langle A_i \rangle_{i \in \omega}$ be a uniformly recursive list of all the primitive recursive sets. We call $i$ a primitive recursive index for $A_i$ (or index, for short). By our hypothesis on $C$, there is a
function \( g \leq_T C' \) such that
\[
|A_i \cap A_n| < |A_i \cap A'_n| \quad \Rightarrow \quad g(i, n) = 0
\]
\[
|A_i \cap A'_n| < |A_i \cap A_n| \quad \Rightarrow \quad g(i, n) = 1
\]
(because the conditions on the left are both \( \Sigma^0_2 \), and so \( C' \) computes a separating set for them).

We inductively define a \( C' \)-computable sequence of indices \( (e_n)_{n \in \omega} \). Let \( e_0 \) be an index for \( \omega \). If \( e_n \) has been defined and \( A_{e_n} = \{ r_0 < r_1 < \cdots \} \) (possibly finite), let \( e'_n \) be an index, uniformly obtained from \( e_n \), such that \( A_{e'_n} = \{ r_0, r_2, \ldots \} \). Now let
\[
A_{e_{n+1}} = A_{e'_n} \cap A'_n \text{ if } g(e'_n, n) = 0, \text{ and }
A_{e_{n+1}} = A_{e'_n} \cap A_n \text{ if } g(e'_n, n) = 1.
\]

By induction on \( n \), one verifies that \( A_{e_n} \) is infinite and \( A_{e_{n+1}} \subseteq A_{e_n} \). Since \( g \leq_T C' \), the numbers \( e_n \) have a uniformly \( C \)-computable approximation \( (e_n, x)_{x \in \omega} \).

Let the ultrafilter base \( F \leq_T C \) be given by \( F_n(x) = A_{e_n, x}(x) \). Then \( F_n =^* A_{e_n} \) is primitive recursive. Since \( F_{n+1} \subseteq^* A'_n \) or \( F_{n+1} \subseteq^* A_n \) for each \( n \), the set \( F \) is an ultrafilter base for the primitive recursive sets.

\[ \square \]
