Abstract

This paper provides a non-asymptotic analysis of linear stochastic approximation (LSA) algorithms with fixed stepsize. This family of methods arises in many machine learning tasks and is used to obtain approximate solutions of a linear system \( \bar{A} \theta = \bar{b} \) for which \( \bar{A} \) and \( \bar{b} \) can only be accessed through random estimates \( \{(A_n, b_n) : n \in \mathbb{N}^*\} \). Our analysis is based on new results regarding moments and high probability bounds for products of matrices which are shown to be tight. We derive high probability bounds on the performance of LSA under weaker conditions on the sequence \( \{(A_n, b_n) : n \in \mathbb{N}^*\} \) than previous works. However, in contrast, we establish polynomial concentration bounds with order depending on the stepsize. We show that our conclusions cannot be improved without additional assumptions on the sequence of random matrices \( \{A_n : n \in \mathbb{N}^*\} \), and in particular that no Gaussian or exponential high probability bounds can hold. Finally, we pay a particular attention to establishing bounds with sharp order with respect to the number of iterations and the stepsize and whose leading terms contain the covariance matrices appearing in the central limit theorems.

1 Introduction

This paper provides a detailed analysis of Linear Stochastic Approximation (LSA) schemes which aim at finding a solution \( \theta^* \) for a linear system of the form \( A \theta = b \). In particular, we analyze LSA with a fixed stepsize \( \alpha > 0 \) which consists in defining a sequence of estimates \( \{\theta_n : n \in \mathbb{N}\} \) for \( \theta^* \) by the recursion

\[
\theta_{n+1} = \theta_n - \alpha \{A_{n+1} \theta_n - b_{n+1}\}, \quad n \in \mathbb{N},
\]

where \( \{(A_n, b_n) : n \in \mathbb{N}^*\} \) is a sequence of i.i.d. random variables used as proxy for \( \bar{A} \in \mathbb{R}^{d \times d} \) and \( \bar{b} \in \mathbb{R}^d \) which are typically unknown. This class of algorithms and the corresponding setting have a long history and important applications in signal processing such as channel equalization and echo cancellation [3, 22]. It has renewed interests in machine learning and computational statistics

Preprint. Under review.
especially for least-square estimation, Reinforcement learning (RL) and Q-learning [4, 7, 38, 35]. The recursion (1) has already been studied in depth in several works which derive asymptotic [31, 22, 6, 3] and non-asymptotic [33, 25, 2, 19, 20, 5, 23, 34, 9, 12] guarantees.

However, in most cases, there is a consistent gap between these two types of analyses. While asymptotic analysis gives important insights on the qualitative convergence of (1) based on statistical key quantities of the problem on hand, they do not provide finite-time convergence, or high probability bounds, necessary to obtain non-asymptotic confidence sets, see [26, 10] and the references therein. On the other hand, non-asymptotic studies are in general too coarse and lose significant statistical information in their derivation. Further, their upper bounds are generally loose when used in predicting the actual performance of LSA. We aim at filling this gap and provide conditions on \( \{ (A_n, b_n) : n \in \mathbb{N}^+ \} \) ensuring tight high probability bounds on the sequence \( \{ \theta_n : n \in \mathbb{N} \} \).

This problem has been addressed in several contributions but at the expense of strong conditions on the sequence \( \{ (A_n, b_n) : n \in \mathbb{N}^+ \} \). [13] provided concentration bounds for non-linear stochastic algorithms under a log-Sobolev condition which turns out to be hard to verify for most applications except for the Euler-Maruyama discretization scheme applied to Stochastic Differential Equation. [27] derived concentration inequalities but assuming that the innovations in (1) are uniformly bounded. In contrast, we aim at giving simple and mild conditions ensuring high probability bounds. More precisely, one of our key contributions (Theorem 1) is to show that under mild conditions on the sequence \( \{ (A_n, b_n) : n \in \mathbb{N}^+ \} \), for any \( \delta \in (0, 1), n \in \mathbb{N} \) and \( u \in \mathbb{R}\),

\[
\mathbb{P}\left( \left\| u^\top (\theta_n - \theta^*) \right\| \leq c \{ \sqrt{n} \alpha \nu + \alpha \} \sqrt{\log(1/\delta)} + c\{ \rho^2_\nu + \alpha \rho^2_0 \} \delta^{-\frac{1}{2}} \right) \geq 1 - \delta,
\]

where \( \rho_\nu \in (0, 1), c > 0 \) is a constant independent of \( n, \alpha, \delta \), and \( p_0 = o(\alpha^{-1/4}) \). In the above, \( \Sigma \) is the unique solution of the Lyapunov equation which naturally appears in central limit theorems for LSA with diminishing stepsize. In addition, we show that the bound we get is tight with respect to \( \alpha \) and \( \delta \) in the case where we only assume that \(-E[A]\) is Hurwitz. Indeed, we provide counterexamples illustrating that for a fixed stepsize \( \alpha \) and under the conditions that we consider, logarithmic dependence in \( 1/\delta \) cannot hold in (2) but only a polynomial one. Regarding the dependence with respect to \( \alpha \), we extend [28] and show that for \( \alpha \) small enough, \( \{ \theta_n : n \in \mathbb{N} \} \) admits a unique stationary distribution \( \pi_\alpha \) and establish a central limit theorem for this family of distribution as \( \alpha \downarrow 0 \) at rate \( \sqrt{\alpha} \) and with asymptotic covariance matrix \( \Sigma \) appearing in (2).

Finally, our proofs rely on a new analysis of product of matrices, extending the recent work of [17]. In particular, we establish conditions ensuring uniform bounds in \( n \) of the \( p \)-th moments of \( Y_n \cdots Y_1 \), where \( \{ Y_n : n \in \mathbb{N}^+ \} \) is a sequence of independent matrices whose expected values have a spectral radius less than \( 1 \). In comparison to existing results, the main challenge that we address here is that the random matrices \( \{ A_n : n \in \mathbb{N}^+ \} \) are not assumed to be almost surely symmetric.

The paper is organized as follows. Section 2 formally discusses the assumptions on LSA for our analysis. Section 3 presents the moment bound for product of random matrices. Using this result, Section 4 shows the high probability concentration inequality (2) and Section 5 shows the tightness of the bounds by deriving a central limit theorem for LSA.

**Notations** Denote \( \mathbb{N}^* = \mathbb{N} \setminus \{0\} \) and \( \mathbb{N}_- = \mathbb{Z} \setminus \mathbb{N}^* \). Let \( d \in \mathbb{N}^* \) and \( Q \) be a symmetric positive definite \( d \times d \) matrix. For \( x \in \mathbb{R}^d \), we denote \( \|x\|_Q = (x^\top Q x)^{1/2} \). For brevity, we set \( \|x\| = \|x\|_{L_2} \). We denote \( \| A \| = \max_{\|x\|_Q = 1} \|Ax\|_Q \), and the subscriptless norm \( \| A \| = \| A \|_{L_2} \) is the standard spectral norm. We denote the condition number of \( Q \) as \( \kappa_Q = \lambda^{-1}_\min(Q) \lambda_{\max}(Q) \). We denote \( \mathbb{S}^{d-1} = \{ x \in \mathbb{R}^d : \|x\|_2 = 1 \} \). Let \( A_1, \ldots, A_N \) be \( d \)-dimensional matrices. We denote \( \prod_{i=1}^j A_i = A_j \cdots A_1 \) and with the convention \( \prod_{i=1}^j A_i = 1_d \) if \( i > j \). We say that a centered random variable (r.v.) \( X \) is sub-Gaussian with variance factor \( \sigma^2 \) and we denote \( X \in \SG(\sigma^2) \) if for all \( \lambda \in \mathbb{R} \),

\[
\log \mathbb{E}[e^{\lambda X}] \leq \lambda^2 \sigma^2/2.
\]

We define the Wasserstein distance of order 2 between two probabilities measure \( \mu \) and \( \nu \) on \( \mathbb{R}^d \) as

\[
W_2(\mu, \nu) = \inf_{\zeta \in \Pi(\mu, \nu)} \int_{\mathbb{R}^{2d}} \|x - y\|^2 d\zeta(x, y),
\]

where \( \Pi(\mu, \nu) \) is the set of probability measures on \( (\mathbb{R}^{2d}, \mathcal{B}(\mathbb{R}^{2d})) \) with marginals \( \mu \) and \( \nu \) respectively. Denote by \( \mathcal{P}_2(\mathbb{R}^d) \) the set of all probability measures on \( \mathbb{R}^d \) with the finite second moment.
2 Linear Stochastic Approximation: Setting and Assumptions

Consider the LSA recursion (1) with a deterministic initial point \( \theta_0 \). The main assumption required in this paper is as follows:

**A1.** \( \{ (A_n, b_n) \}_{n \in \mathbb{N}^+} \) is an i.i.d. sequence satisfying the following conditions.

(i) \( \mathbb{E}[b_1] = \bar{b} \) and there exists \( C_b > 0 \) such that, for any \( u \in S^{d-1}, u^\top (b_1 - \bar{b}) \in \text{SG}(C_b^2) \).

(ii) There exists \( C_A > 0 \) such that \( \|A_1\| \leq C_A \) almost surely.

(iii) The matrix \( -\bar{A} = -\mathbb{E}[A_1] \) is Hurwitz, i.e., for any eigenvalue \( \lambda \) of \( \bar{A} \), \( \text{Re}(\lambda) > 0 \).

Both conditions A1-(i), (ii) are standard in analysis of LSA, e.g., in [11, 34, 24]. Meanwhile, A1-(iii) guarantees the existence of a unique solution \( \theta^* \) to \( A \theta = \bar{b} \). It is also a sufficient and necessary condition for the solution of the ordinary differential equation \( \dot{\theta}_t = -A\theta_t \) to converge exponentially to \( \theta^* \) [18, Lemma 4.1.2]. The same kind of result holds for the discrete system \( \theta_{n+1}^d - \theta_n^d = -\alpha \bar{A} \theta_n^d \).

**Proposition 1.** Assume that \( -\bar{A} \) is a Hurwitz matrix. Then there exists a unique positive definite matrix \( Q \) satisfying the Lyapunov equation \( \bar{A}^\top Q + Q \bar{A} = \mathbf{1} \). In addition, setting

\[
a = \|Q\|^{-1/2}, \quad \text{and} \quad \alpha_\infty = (1/2)\|\bar{A}\|_Q^{-1}\|Q\|^{-1},
\]

then for any \( \alpha \in (0, \alpha_\infty) \), we get \( \|I - \alpha \bar{A}\|_Q^2 \leq 1 - \alpha \alpha \). If in addition \( \alpha \leq \|Q\|^2 \) then \( 1 - \alpha \alpha \geq 1/2 \).

This result is well known but its proof can be found in Appendix A.1 for completeness. The above proposition implies that the discrete system converges exponentially as \( \|\theta_{n+1}^d\| \leq \sqrt{n}Q^{(1 - \alpha \alpha)^n/2}\|\theta_0^d\| \) for \( \alpha \in (0, \alpha_\infty) \).

Recall that the aim of this paper is to derive high probability bounds on \( u^\top \{\theta_n - \theta^*\} \) for any \( n \in \mathbb{N} \), \( u \in S^{d-1} \). Below, we present a counterexample to show that under only A1, if \( \alpha > 0 \) is fixed, then there exists \( \bar{p} > 0 \) such that \( \lim_{n \to +\infty} \mathbb{E}[|\theta_n - \theta^*|^p] = +\infty \) for \( p \geq \bar{p} \). As a corollary, it is impossible to obtain exponential high probability bounds for \( \{\|\theta_n - \theta^*\| : n \in \mathbb{N}\} \).

**Example 1.** Consider (1) with \( d = 1 \) taking \( b_n = 0 \) for any \( n \in \mathbb{N}^+ \) and for \( \{A_n : n \in \mathbb{N}^+\} \) an i.i.d. sequence of biased Rademacher r.v.s with parameter \( q_A \in (1/2, 1) \):

\[
A_n = \begin{cases} 
1 & \text{with probability } q_A, \\
-1 & \text{with probability } 1 - q_A.
\end{cases}
\]

This choice is associated with \( \theta^* = 0 \) and corresponds to the recursion: \( \theta_n = \prod_{k=1}^n (1 - \alpha A_k)\theta_0 \), for some \( \theta_0 \neq 0 \). For any \( p \geq 1 \) and \( \alpha \in (0, 1) \), we have by definition,

\[
\mathbb{E}[|\theta_n|^p] = (q_A(1 - \alpha)^p + (1 - q_A)(1 + \alpha)^p)^n|\theta_0|^p.
\]

Using the lower bounds \( (1 - \alpha)^p \geq 1 - \alpha p \) and \( (1 + \alpha)^p \geq 1 + \alpha p + p(p - 1)\alpha^2/2 \), we get for any \( p \geq 1 \) and \( \alpha \in (0, 1) \),

\[
\mathbb{E}[|\theta_n|^p] \geq (1 - p\alpha[(2q_A - 1) - (p - 1)\alpha(1 - q_A)/2])^n|\theta_0|^p.
\]

If \( \alpha \in (0, 1) \) is fixed, then for any \( p > \bar{p}_q \alpha = 1 + 2(2q_A - 1)/(\alpha(1 - q_A)) \), we have

\[
\lim_{n \to +\infty} \mathbb{E}[|\theta_n|^p] = +\infty.
\]

On the other hand, if \( \alpha \in (0, 2(2q_A - 1)/(1 - q_A)) \), then

\[
\lim_{n \to +\infty} \mathbb{E}[|\theta_n|^2] = 0.
\]

Therefore \( \{\theta_n : n \in \mathbb{N}\} \) converges in distribution to the Dirac measure at 0 which corresponds to the unique stationary distribution of this sequence as a Markov chain. In such a case, this distribution admit \( p \) moments for any \( p \geq 0 \).

However, this result is specific to this particular case and does not hold if only A1 holds. Consider \( \{\theta_n : n \in \mathbb{N}\} \) defined by (1) with \( \{A_n : n \in \mathbb{N}^+\} \) given in (4) and \( \{b_n : n \in \mathbb{N}^+\} \) be an i.i.d. sequence of zero-mean Gaussian random variables with unit variance independent of \( \{A_n : n \in \mathbb{N}^+\} \). We show in Appendix A.2 that there exists \( \alpha_{2, \infty} \) such that for any \( \alpha \in (0, \alpha_{2, \infty}) \), the Markov chain \( \{\theta_n : n \in \mathbb{N}\} \) admits a unique invariant distribution \( \pi_\alpha \) for any \( \alpha > 0 \). Further, for any \( \alpha \in (0, \alpha_{2, \infty}) \), there exists \( p_\alpha \geq 1 \) such that \( \int_\mathbb{R} |\theta|^p \pi_\alpha(\theta) = +\infty \) for any \( p \geq p_\alpha \).

It is, however, possible to obtain any \( p \)-th moment uniform bound for \( \{\|\theta_n - \theta^*\| : n \in \mathbb{N}\} \) by strengthening A1-(iii) to:
A2. There exist \( \tilde{a} \in (0, 1) \), \( \tilde{a}_\infty > 0 \) and a definite positive \( d \)-dimensional matrix \( \tilde{Q} \) such that almost surely, for any \( \alpha \in (0, \tilde{a}_\infty) \), \( \|I - \alpha A_1\|_{\tilde{Q}} < 1 - \tilde{a}\alpha \).

Examples such that A2 holds include regularized linear regression, where we take \( A_1 = \lambda I + \alpha_1 a_1^T \), for some \( \lambda > 0 \) and under the assumption that \( \|a_1\| \) is bounded almost surely. The LSA recursion (1) approximates the solution to \((\lambda I + E[a_1 a_1^T])\theta = \bar{b}\) which is guaranteed to have a unique solution.

On the other hand, examples where A2 does not hold are common. For this, we consider TD(0) learning with linear function approximation. For a Markov Reward Process with \( X \) as the state space, \( P : X \times \mathcal{X} \rightarrow [0, 1] \) as the transition probability, \( R : X \rightarrow \mathbb{R} \) as the reward function, and \( \gamma \in (0, 1) \) as a discount factor, TD(0) learning is described as in (1) with

\[
A_n = \phi(x_n)\{\phi(x_n) - \gamma \phi(x_n')\}, \quad b_n = R(x_n)\phi(x_n),
\]

where \( \phi : X \rightarrow \mathbb{R}^d \) is a feature map. A typical setting is when \( x_n \) is drawn from the stationary distribution of \( P \) and \( x_n' \sim P(x_n, \cdot) \). It is easy to verify A1 provided that \( \|\phi(x)\|, R(x) \) are bounded for all \( x \in X \) [36]. However, A2 is violated as \( A_n \) is only rank-one.

Our next endeavor is to establish moment estimates on the product below:

\[
\Gamma_{m,n}^{(\alpha)} = \prod_{i= \min(n,m)}^n (I - \alpha A_i), \quad m,n \in \mathbb{N}^*, \quad m \leq n.
\]

We also define its expected value as \( G_{m,n}^{(\alpha)} = \mathbb{E}[\Gamma_{m,n}^{(\alpha)}] = (I - \alpha A)^{n-m+1} \).

The above product naturally appears after re-centering the LSA recursion (1). For any \( n \in \mathbb{N}^* \),

\[
\theta_n - \theta^* = (I - \alpha A_n)\{\theta_{n-1} - \theta^*\} + \alpha \varepsilon_n, \quad \varepsilon_n = b_n - \bar{b} - \{A_n - \bar{A}\} \theta^*. \quad (7)
\]

An easy induction implies that

\[
\theta_n - \theta^* = \tilde{\theta}_n^{(\text{tr})} + \tilde{\theta}_n^{(b)}, \quad \tilde{\theta}_n^{(\text{tr})} = \Gamma_{0,n}^{(\alpha)}\{\theta_0 - \theta^*\}, \quad \tilde{\theta}_n^{(b)} = \alpha \sum_{j=1}^n \Gamma_{j+1,n}^{(\alpha)} \varepsilon_j. \quad (8)
\]

The decomposition (8) highlights the two sources of error in the estimation of \( \theta^* \) by \( \{\theta_n : n \in \mathbb{N}\} \) which will be separately tackled: \( \{\tilde{\theta}_n^{(\text{tr})} : n \in \mathbb{N}\} \) corresponds to the transient (or bias) term and \( \{\tilde{\theta}_n^{(b)} : n \in \mathbb{N}\} \) to the fluctuation term. Both errors are controlled by the product of matrices \( \Gamma_{m,n}^{(\alpha)} \), thereby motivating the study of the moment bound on \( \Gamma_{1,n}^{(\alpha)} \) as we present next.

3 Moment and High-probability Bounds for Products of Random Matrices

Recall from Proposition 1 that the expected value \( G_{1,n}^{(\alpha)} = \mathbb{E}[\Gamma_{1,n}^{(\alpha)}] \) decays exponentially with \( n \), here we expect a similar phenomenon to hold for the moment bound of \( \Gamma_{1,n}^{(\alpha)} \). Precisely, in this section, we show that if \( p \) is fixed, then there exists \( \alpha_p > 0 \) such that for any \( \alpha \in (0, \alpha_p] \), the \( p \)-th moment of \( \Gamma_{m,n}^{(\alpha)} \) decays exponentially with \( n - m \).

To facilitate our discussions, we introduce the following notations. For \( B \in \mathbb{R}^{d \times d} \), we denote by \((\sigma_\ell(B))_{\ell=1}^d\) its singular values. For \( p \geq 1 \), the Schatten \( p \)-norm is denoted by \( \|B\|_p = \left\{ \sum_{\ell=1}^d \sigma_\ell^p(B) \right\}^{1/p} \). For \( p, q \geq 1 \) and random matrix \( X \), we write \( \|X\|_{p,q} = \{\mathbb{E}[\|X\|^p_2]\}^{1/q} \).

In the following, we present the main technical result on the product of general random matrices. The proof is based on the framework introduced in [17].

**Proposition 2.** Let \( \{Y_\ell : \ell \in \mathbb{N}\} \) be an independent sequence and \( P \) be a positive definite matrix. Assume that for each \( \ell \in \mathbb{N} \) there exist \( m_\ell \in (0, 1) \) and \( \sigma_\ell > 0 \) such that \( \|E[Y_\ell]\|_P \leq 1 - m_\ell \) and \( \|Y_\ell - E[Y_\ell]\|_P \leq \sigma_\ell \) almost surely. Define \( Z_n = \prod_{\ell=0}^n Y_\ell = Y_n Z_{n-1} \), for \( n \geq 1 \) and starting from \( Z_0 \). Then, for any \( 2 \leq q \leq p \) and \( n \geq 1 \),

\[
\|Z_n\|_{p,q}^2 \leq \kappa_p \prod_{\ell=1}^n (1 - m_\ell + (p-1)\sigma_\ell^2)\|P^{1/2}Z_0P^{-1/2}\|_{p,q}^2, \quad (9)
\]

where \( \kappa_p = \lambda_{\min}(P)^{1/(p)}\lambda_{\max}(P) \).
Proof of Proposition 2. Let $2 \leq q \leq p$. Consider the following decomposition $Z_n = Y_nZ_{n-1} = (Y_n - E[Y_n])Z_{n-1} + E[Y_n]Z_{n-1}$. Therefore, we obtain for any $n \in N$,

$$f_P(Z_n) = A_n + B_n, \quad A_n = f_P((Y_n - E[Y_n])Z_{n-1}) + B_n = f_P(E[Y_n])f_P(Z_{n-1}),$$

where $f_P : \mathbb{R}^{d \times d} \rightarrow \mathbb{R}^{d \times d}$ is defined for any $B \in \mathbb{R}^{d \times d}$ by $f_P(B) = P^{1/2}BP^{-1/2}$. Since $E[A_n|B_n] = 0$, [17, Proposition 4.3] (see Proposition 10 in Appendix B) implies that

$$\|f_P(Z_n)\|_{p,q}^2 \leq \|B_n\|_{p,q}^2 + (p-1)\|A_n\|_{p,q}^2. \quad (10)$$

It remains to bound the two terms on the right hand side. To this end, we use [16, Theorem 6.20] which implies that for any $B_1, B_2 \in \mathbb{R}^{d \times d}$,

$$\|B_1B_2\|_{p,q} \leq \|B_1\|\|B_2\|_{p,q}. \quad (11)$$

As a result and using that for any $B \in \mathbb{R}^{d \times d}$, $\|B\|_p = \|f_P(B)\|_p$, and $\|Y_n - E[Y_n]\|_p \leq \sigma_n$ we get

$$\|A_n\|_{p,q} = (\mathbb{E}[\|f_P(Y_n - E[Y_n])f_P(Z_{n-1})\|_{p,q}^q])^{1/q} \leq (\mathbb{E}[\|Y_n - E[Y_n]\|_p^q\|f_P(Z_{n-1})\|_{p,q}^q])^{1/q} \leq \sigma_n\|f_P(Z_{n-1})\|_{p,q}. \quad (12)$$

Similarly, applying $\|E[Y_n]\|_{p,q}^q \leq 1 - m_n$

$$\|B_n\|_{p,q}^2 = (\mathbb{E}[\|f_P(Y_n)f_P(Z_{n-1})\|_{p,q}^q])^{2/q} \leq (\mathbb{E}[\|E[Y_n]\|_p^q\|f_P(Z_{n-1})\|_{p,q}^q])^{2/q} \leq (1 - m_n)\|f_P(Z_{n-1})\|_{p,q}^2. \quad (13)$$

Combining (12) and (13) in (10) yields for any $n \in N^*$, $\|f_P(Z_n)\|_{p,q}^2 \leq (1 - m_n + (p-1)\sigma_n^2)\|f_P(Z_{n-1})\|_{p,q}^2$. The proof is then completed upon using (11) which implies that $\|Z_n\|_{p,q} = \|P^{-1/2}f_P(Z_n)P^{1/2}\|_{p,q} \leq \sqrt{\mathbb{E}[\|f_P(Z_n)\|_{p,q}^2]}$. ✷

In order to bound $\Gamma^{(\alpha)}_{1:n}$ using Proposition 2, we identify the latter with $Y_\ell = I - \alpha A_\ell$, $\ell \geq 1$, $Y_0 = I$. As $-A$ is Hurwitz, applying Proposition 1 yields $\|E[Y_\ell]\|_{Q}^2 = \|I - \alpha A\|_{Q}^2 \leq 1 - \alpha a$. Further, A 1-(ii) ensures that almost surely,

$$\|Y_\ell - E[Y_\ell]\|_Q = \alpha\|A_\ell - \bar{A}\|_Q \leq 2\alpha\sqrt{\kappa_Q}C_A = b_Q\alpha.$$ 

Therefore, (9) holds with $m_\ell = \alpha a$ and $\sigma_\ell = b_Q\alpha$. Noting that as $\|I\|_p = d^{1/p}$, we obtain the following corollary.

Corollary 1. Assume $A 1-(ii)-(iii)$. Then, for any $\alpha \in [0, \alpha_\infty]$, $2 \leq q \leq p$, and $n \in N$,

$$\mathbb{E}[\|\Gamma^{(\alpha)}_{1:n}\|_Q^q] \leq \|\Gamma^{(\alpha)}_{1:n}\|_{p,q} \leq \sqrt{\kappa_Q}d^{1/p}(1 - \alpha a + (p-1)\alpha^2 b_Q^2/2^n)^{1/2}, \quad (14)$$

where $\alpha_\infty$ was defined in (3), and

$$b_Q = 2\sqrt{\kappa_Q}C_A. \quad (15)$$

Note that Corollary 1 shows sup $E[\|\Gamma^{(\alpha)}_{1:n}\|_Q^p] < +\infty$ for any $\alpha \in (0, \alpha_{p,\infty})$, where

$$\alpha_{p,\infty} = \alpha_\infty \wedge \alpha/(2b_Q^2(p-1)). \quad (16)$$

This kind of condition relating the choice $\alpha$ with the order $p$ of the moment to be bounded is necessary as illustrated in Example 1. The above corollary further leads to the high-probability bound:

Corollary 2. Assume $A 1-(ii)-(iii)$. Then, for any $\alpha \in (0, \alpha_\infty)$ where $\alpha_\infty$ was defined in (3), $\delta \in (0, 1)$ and $n \in N$, with probability at least $1 - \delta$,

$$\|\Gamma^{(\alpha)}_{1:n}\| \leq \sqrt{\kappa_Q}\exp[-(\alpha a - \alpha^2 b_Q^2/2 + b_Q\alpha\sqrt{2\log(d/\delta)})].$$

Proof. The result follows from combining Corollary 1 with $p = q$ and Lemma 1 in Appendix B applied with $A = (-\log(\kappa_Q) + \alpha a n + b_Q^2(\alpha^2 n))/2$, $B = \alpha^2 b_Q^2 n/2$ and $C = d, p_0 = 2, p_1 = +\infty$. ✷
The result which we obtain in Corollary 2 is tight with respect to $\delta$, as illustrated via the following
example that continues from Example 1.

**Example (Continuation of Example 1).** Consider \( \{\theta_n : n \in \mathbb{N}\} \) defined by (1) with \( \{A_n : n \in \mathbb{N}^*\} \) given in (4) and \( b_n = 0 \) for any \( n \in \mathbb{N}^* \). Define

\[
\varphi_q(\alpha) = qA \log \left( \frac{1 + \alpha}{1 - \alpha} \right) - \log(1 + \alpha), \quad \bar{\alpha}_q = \sup \{\bar{\alpha} > 0 : \varphi_q(\alpha) > 0, \forall \alpha \in (0, \bar{\alpha})\} . \tag{17}
\]

Note that \( \varphi_q(\alpha) \sim \alpha (2qA - 1) \) as \( \alpha \to 0 \). Therefore since \( qA > 1/2 \), \( \{\bar{\alpha} > 0 : \varphi_q(\alpha) > 0 \text{ for any } \alpha \in (0, \bar{\alpha})\} \neq \emptyset \) and \( \bar{\alpha}_q \) is well-defined. Consider also \( \tilde{\varphi}_q(\alpha) = \varphi_q(\alpha) \log^{-1}[(1 + \alpha)/(1 - \alpha)] \). Then, we show in Appendix B that for any \( \bar{\delta} \in (e^{-2n\tilde{\varphi}_q(\alpha)}, 1) \) and \( \tilde{\delta} \in (e^{-n\tilde{\varphi}_q(\alpha)/(qA(1-\alpha^2))}, 1) \),

\[
\mathbb{P} \left( \theta_n \geq \exp \left( -\varphi_q(\alpha)n + \log \left( \frac{1 + \alpha}{1 - \alpha} \right) \sqrt{\frac{n \log(1/\tilde{\delta})}{2}} \right) \right) \leq \tilde{\delta} , \tag{18}
\]

\[
\mathbb{P} \left( \theta_n \geq \exp \left( -\varphi_q(\alpha)n + \log \left( \frac{1 + \alpha}{1 - \alpha} \right) \sqrt{\frac{nqA(1-qA) \log(1/\bar{\delta}) + n \log(n)}{2}} \right) \right) \geq \bar{\delta} . \tag{19}
\]

Note that the bound given by (18) and (19) shows that the tail distribution associated with \( \theta_n \)
behaves as a log-normal one. Indeed, if \( \xi \) is a zero-mean one dimensional Gaussian distribution
with unit variance, then an easy computation shows that for any \( \sigma > 0 \), \( \mathbb{P}(e^{\sigma \xi} \geq t) \sim (2\pi \sigma^2)^{-1/2} \log^{-1}(t) \exp(-(2\sigma^2)^{-1}t^2) \) as \( t \to \infty \), therefore, to have \( \mathbb{P}(e^{\sigma \xi} \geq t_\delta) \leq \delta \) for a small
\( \delta > 0 \), then \( t_\delta \) has to be of order \( \exp(\sigma \sqrt{\log(1/\delta)}) \).

We conclude the section with a complementary result of Corollary 1 that does not require A1-(ii):

**Proposition 3.** Assume A1-(iii), \( \|A_1 - \bar{A}\| \in \text{SG}(C'_A) \) for some \( C'_A > 0 \). Then, for any \( \alpha \in (0, \alpha_\infty) \) where \( \alpha_\infty \) was defined in (3), \( 2 \leq q \leq p \), and \( n \in \mathbb{N} \),

\[
\mathbb{E}^{1/q} \left[ \|\Gamma^{(\alpha)}_{1:n}\|^q \right] \leq \|\Gamma^{(\alpha)}_{1:n}\|_{p,q} \leq \sqrt{Q} d^{1/p}(1 - a\alpha + q(p - 1)(b'_q)^2 \alpha^2)^n/2 , \tag{20}
\]

where \( b'_q = 2\sqrt{Q} C'_A \).

The proof is similar to that of Proposition 2 and it can be found in Appendix B.

## 4 Finite-time High-probability Bounds for LSA

Relying on the results established in Section 3 and the decomposition (8), we derive in this section
high probability bounds on \( u^T \{\theta_n - \theta^*\} \) for any \( n \in \mathbb{N} \) and \( u \in \mathbb{S}^{d-1} \), where \( \{\theta_n : n \in \mathbb{N}\} \) is defined in (1). We begin our study with the transient term \( \tilde{\theta}_n^{(\alpha)} \) defined in (8). The proof of the following statement is given in Appendix C.1.

**Proposition 4.** Assume A1 and let \( p_0 \geq 2 \). Then, for any \( n \in \mathbb{N}^* \), \( \alpha \in (0, \alpha_{p_0, \infty}) \), where \( \alpha_{p_0, \infty} \) is defined in (16), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1) \) it holds with probability at least \( 1 - \delta \) that

\[
|u^T \Gamma^{(\alpha)}_{1:n}(\theta_0 - \theta^*)| \leq \sqrt{c Q d^{1/p_0}(1 - a\alpha/4)^n} \|\theta_0 - \theta^*\| \delta^{1/p_0} ,
\]

where \( a \) was defined in (3).

Proposition 4 only provides a polynomial high probability bound with respect to \( \delta \). This is due to the fact that only polynomial moments of \( \|\Gamma^{(\alpha)}_{1:n}\| \) up to a maximal order are uniformly bounded in the number of iterations \( n \).

We now turn on the fluctuation term \( \tilde{\theta}_n^{(\alpha)} \) defined in (8). We note that under A1, the sequence
\( \{\epsilon_n : n \in \mathbb{N}\} \) defined in (7) is i.i.d.. From this observation and following [12], we consider the decomposition

\[
\tilde{\theta}_n^{(\alpha)} = \alpha \sum_{j=1}^n f_{j+1:n}(\epsilon_j = J_{n}^{(\alpha,0)} + H_{n}^{(\alpha,0)} , \tag{21}
\]
where \( \{(J_n^{(\alpha,0)}, H_n^{(\alpha,0)}) : n \in \mathbb{N}\} \) are defined by induction for \( n \geq 0 \) as:

\[
J_n^{(\alpha,0)} = (1 - \alpha \bar{A}) J_{n-1}^{(\alpha,0)} + \alpha \varepsilon_n, \quad J_0^{(\alpha,0)} = 0, \\
H_n^{(\alpha,0)} = (1 - \alpha A_n) H_{n-1}^{(\alpha,0)} - \alpha (A_{n+1} - \bar{A}) J_n^{(\alpha,0)}, \quad H_0^{(\alpha,0)} = 0.
\] (22)

The latter recurrence can be written as

\[
J_n^{(\alpha,0)} = \alpha \sum_{j=1}^{n} \sigma_j \varepsilon_j, \quad H_n^{(\alpha,0)} = -\alpha \sum_{j=1}^{n} \sigma_j (A_j - \bar{A}) J_{j-1}^{(\alpha,0)}.
\]

Note that \( J_n^{(\alpha,0)} \) is a linear statistics of the random variables \( \{\varepsilon_j : j \in \{1, \ldots, n\}\} \) which are centered and i.i.d. under \( A \). In our next results, we show that \( J_n^{(\alpha,0)} \) is the leading term as the stepsize \( \alpha \downarrow 0 \). Denote for any \( n \in \mathbb{N}^* \) and \( \alpha > 0 \), the covariance matrix of \( J_n^{(\alpha,0)} \) as

\[
\Sigma_n^\alpha = \text{Cov}(J_n^{(\alpha,0)}). \tag{23}
\]

**Proposition 5.** Assume A1. Then for any \( n \in \mathbb{N}^* \), \( \alpha \in (0, \alpha_\infty] \), where \( \alpha_\infty \) is defined in (3), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1) \), it holds with probability at least \( 1 - \delta \),

\[
|u^T J_n^{(\alpha,0)}| < D_1 \sqrt{u^T \Sigma_n^\alpha u \log(2/\delta)} + \alpha \sqrt{1 + \log(1/(\alpha \delta))} D_2 \log^{3/2}(2/\delta), \tag{24}
\]

where \( D_1 = 60 \sqrt{2} e^{4/3} \) and \( D_2 \) is defined in (50).

The proof of Proposition 5 is postponed to Appendix C.2.

We analyze further the covariance associated with \( J_n^{(\alpha,0)} \) and its dependence with respect to \( n \) and \( \alpha \). First, note that for any \( \alpha \in (0, \alpha_\infty) \), \( \{\Sigma_n^\alpha : n \in \mathbb{N}^*\} \) converges to \( \alpha \Sigma^\alpha \) as \( n \to \infty \) where \( \Sigma^\alpha = \alpha \sum_{k=0}^{\infty} G_{1,k} \Sigma \Gamma_{1,k}^T \) is the unique solution of the Riccati equation

\[
\bar{A} \Sigma^\alpha + \Sigma^\alpha \bar{A}^T - \alpha \bar{A} \Sigma^\alpha \bar{A}^T = \Sigma_c, \quad \text{with} \quad \Sigma_c = \mathbb{E}[\varepsilon_1 \varepsilon_1^T]. \tag{25}
\]

Indeed, using Proposition 1, we easily get that for any \( n \geq 0 \),

\[
\|\Sigma_n^\alpha - \alpha \Sigma^\alpha\| \leq \alpha^2 \sum_{k>n} \|G_{1,k}\|^2 \|\Sigma_c\| \leq \alpha^2 \Sigma \|\Sigma_c\| (1 - \alpha\alpha)^n. \tag{26}
\]

We now give an expansion of \( \Sigma^\alpha \) with respect to \( \alpha \). It is well-known that as \( \alpha \downarrow 0 \), \( \Sigma^\alpha \) converges to \( \Sigma \), the unique solution of the Lyapunov equation (see [32, Lemma 9.1])

\[
\bar{A} \Sigma + \Sigma \bar{A}^T = \Sigma_c. \tag{27}
\]

Our next result states this convergence is of the order of the stepsize \( \alpha \).

**Proposition 6.** Assume that A1-(iii) holds. Then, for any \( \alpha \in (0, \alpha_\infty] \), where \( \alpha_\infty \) is defined in (3),

\[
\|\Sigma^\alpha - \Sigma\|_Q \leq \alpha a^{-1} \|\bar{A} \Sigma \bar{A}^T\|_Q,
\]

where \( \Sigma^\alpha \) and \( \Sigma \) are defined in (25) and (27) respectively and \( a \) is given in (3).

The proof is given in Appendix C.3. The last step in bounding \( \theta_n^{(\alpha)} \) is to consider \( H_n^{(\alpha,0)} \). We proceed similarly to (22) and consider the decomposition \( H_n^{(\alpha,0)} = J_n^{(\alpha,1)} + H_n^{(\alpha,1)} \), where \( \{(J_n^{(\alpha,1)}, H_n^{(\alpha,1)}) : n \in \mathbb{N}\} \) are defined by induction for \( n \geq 0 \) as:

\[
J_n^{(\alpha,1)} = (1 - \alpha \bar{A}) J_{n-1}^{(\alpha,1)} - \alpha (A_{n+1} - \bar{A}) J_n^{(\alpha,0)}, \quad J_0^{(\alpha,1)} = 0, \\
H_n^{(\alpha,1)} = (1 - \alpha A_n) H_{n-1}^{(\alpha,1)} - \alpha (A_{n+1} - \bar{A}) J_n^{(\alpha,0)}, \quad H_0^{(\alpha,1)} = 0. \tag{28}
\]

In our next results, we bound each term of this decomposition separately.

**Proposition 7.** Assume A1 and let \( p_0 \geq 2 \). Then, for any \( n \in \mathbb{N} \), \( \alpha \in (0, \alpha_{p_0,\infty}) \), where \( \alpha_{p_0,\infty} \) is defined in (16), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1/2) \), with probability at least \( 1 - 2\delta \), it holds

\[
|u^T J_n^{(\alpha,1)}| < eD_3 \alpha \log^3(1/\delta), \quad |u^T H_n^{(\alpha,1)}| < D_4 \alpha p_0^2 \delta^{-1}/p_0, \tag{29}
\]

where \( D_3 \) and \( D_4 \) are given in (58) and (61), respectively.
The proof of Proposition 7 is postponed to Appendix C.4. Now we are ready to combine the previous bounds and to state the main result of this section.

**Theorem 1.** Assume A1 and let \( p_0 \geq 2 \). Then, for any \( n \in \mathbb{N} \), \( \alpha \in (0, \alpha_{p_0, \infty}) \), where \( \alpha_{p_0, \infty} \) is defined in (16), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1/4) \), with probability at least \( 1 - 4\delta \), it holds

\[
\alpha^{-1/2}|u^\top (\theta_n - \theta^*)| < D_1 \sqrt{\{u^\top \Sigma^u u\} \log(2/\delta) + \alpha^{1/2} q^{(1)}(\alpha, \delta) + (1 - \alpha/4)^n \Delta^{(1)}(\alpha, \delta)},
\]

where \( \Sigma^u \) is the unique solution of (25), \( D_1 = 6\sqrt{3}e^{-3/2} \), \( \alpha \) is defined in (3),

\[
q^{(1)}(\alpha, \delta) = e(D_1 \log^2(1/\delta) + \sqrt{1 + \log(1/\alpha)^2} D_2 \log(2/\delta) + D_4 \rho^2 \delta^{-1/\rho_0}, \]

\[
\Delta^{(1)}(\alpha, \delta) = D_1 \sqrt{\alpha^{-1}\kappa_Q |\Sigma_e| \log(2/\delta) + \kappa_Q^{1/2} \theta_0 - \theta^* |\alpha^{-1/2}\delta^{-1/\rho_0},
\]

where \( \kappa_Q \) and \( \Sigma_e \) are defined in (3) and (25) respectively.

**Proof.** The proof follows from the decomposition

\[
u^\top(\theta_n - \theta^*) = u^\top \Gamma_{1:n}^{(1)}(\theta_0 - \theta^*) + u^\top J_n^{(\alpha,0)} + u^\top J_n^{(\alpha,1)} + u^\top H_n^{(\alpha,1)},
\]

where \( J_n^{(\alpha,0)} \), \( J_n^{(\alpha,1)} \) and \( H_n^{(\alpha,1)} \) are defined in (22)-(28), the union bound and Proposition 4, Proposition 5, (26) and Proposition 7.

We now discuss the high probability bound (30). First, note that the term \( \Delta^{(1)}(\alpha, \delta) \), and in particular the initial condition vanishes exponentially fast in the number of iterations \( n \). In addition, \( q^{(1)}(\alpha, \delta) \) and \( \Delta^{(1)}(\alpha, \delta) \) are of order \( \delta^{-1/\rho_0} \) as \( \delta \to 0 \) and therefore (30) provides polynomial high probability bounds on LSA. However, this conclusion is expected as illustrated in Example 1. Finally, the discussion of (30) with respect to \( \alpha \) is postponed to the next section.

Under A2 we can provide a better bound for \( H_n^{(\alpha,1)} \).

**Proposition 8.** Assume A1 and A2. Then, for any \( n \in \mathbb{N} \), \( \alpha \in (0, \alpha_{\infty} \wedge \alpha_{\infty}) \), where \( \alpha_{\infty} \) is defined in (3), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1/2) \), with probability at least \( 1 - 2\delta \), it holds

\[
|u^\top J_n^{(\alpha,1)}| < eD_3 \alpha \log^2(1/\delta), \quad |u^\top H_n^{(\alpha,1)}| < eD_5 \alpha \log^2(1/\delta),
\]

where \( D_3 \) and \( D_5 \) are given in (58) and (62) respectively.

As a result, we can establish exponential high probability bounds with respect to \( \delta \).

**Theorem 2.** Assume A1 and A2. Then, for any \( n \in \mathbb{N} \), \( \alpha \in (0, \alpha_{\infty} \wedge \alpha_{\infty}) \), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1/4) \), with probability at least \( 1 - 4\delta \), it holds

\[
\alpha^{-1/2}|u^\top (\theta_n - \theta^*)| < D_1 \sqrt{\{u^\top \Sigma^u u\} \log(2/\delta) + \alpha^{1/2} q^{(2)}(\alpha, \delta) + (1 - \alpha/4)^n \Delta^{(2)}(\alpha, \delta)},
\]

where \( D_1 = 6\sqrt{3}e^{-3/2} \), \( \Sigma^u \) is solution of (25),

\[
q^{(2)}(\alpha, \delta) = e(D_3 + D_5) \log^2(1/\delta) + \sqrt{1 + \log(1/\alpha)^2} D_2 \log(2/\delta) + \Delta^{(2)}(\alpha, \delta) = D_1 \sqrt{\alpha^{-1}\kappa_Q |\Sigma_e| \log(2/\delta) + \kappa_Q^{1/2} \theta_0 - \theta^* |\alpha^{-1/2}\delta^{-1/\rho_0},
\]

where \( \kappa_Q \) and \( \Sigma_e \) are defined in (25).

**Proof.** The proof follows the lines of Theorem 1 with Proposition 8 used instead of Proposition 7.

---

5 **Optimality of the derived bounds with respect to \( \alpha \): analysis of \( (\theta_n)_{n \in \mathbb{N}} \) as a Markov chain**

In this section, we study the sequence \( \{\theta_n : n \in \mathbb{N}\} \) defined in (1) as a Markov chain. This perspective will allow us to show that the bounds that we derived in Theorem 1 are near-Berstein high probability bounds with respect to the stepsize \( \alpha \). Denote by \( R_\alpha \) the Markov kernel associated with \( \{\theta_n : n \in \mathbb{N}\} \). First, we show that if \( \alpha \) is small enough then \( R_\alpha \) is geometrically ergodic with respect to the Wasserstein distance of order 2 denoted by \( W_2 \) and give a representation of its stationary distribution as an infinite sum.

8
Theorem 3. Assume A1. Then, for any $\alpha \in (0, \alpha_{2, \infty})$, where $\alpha_{2, \infty}$ is defined in (16), $R_\alpha$ admits a unique stationary distribution $\pi_\alpha \in \mathcal{P}_2(\mathbb{R}^d)$ and for any $n \in \mathbb{N}$,

$$W_2^2(\delta_\theta R_n, \pi_\alpha) \leq \sqrt{kQd(1-\alpha\gamma/2)^n} \int_{\mathbb{R}^d} \|\tilde{\theta} - \theta\|^2 d\pi_\alpha(\tilde{\theta}).$$

(34)

Further, if $\{(A_k, b_k) : k \in \mathbb{N}_-\}$ is any sequence of i.i.d. random variables with the same distribution as $(A_1, b_1)$, then the following limit exists almost surely and in $L^2$ and has distribution $\pi_\alpha$:

$$\theta_\infty^{(\alpha)} = \lim_{n \to -\infty} \theta_n^{(\alpha, \leftarrow)}; \quad \theta_n^{(\alpha, \leftarrow)} = \alpha \sum_{k=n}^1 \Gamma_{k; 0} b_{k-1}, \quad \Gamma_{k; 0} = \prod_{i=k}^0 (I_d - \alpha A_i).$$

(35)

The proof is postponed to Appendix E.1. Based on Theorem 1, we easily get concentration bounds for the family of distributions $\{\pi_\alpha : \alpha \in (0, \alpha_{2, \infty})\}$ around $\theta^*$.

Theorem 4. Assume A1 and let $p_0 \geq 2$. Then, for any $\alpha \in (0, \alpha_{p_0, \infty})$, where $\alpha_{p_0, \infty}$ is defined in (16), $u \in \mathbb{S}^{d-1}$ and $\delta \in (0, 1/4)$, with probability at least $1 - 4\delta$, it holds

$$\alpha^{-1/2} \|u^\top (\tilde{\theta}_\infty^{(\alpha)} - \theta^*)\| < D_1 \sqrt{\epsilon D_1 \log(2/\delta) + \alpha^{-1/2}[n^{-1/2}||A\Sigma \tilde{\theta}\|^2 + q^1(\alpha, \delta)],}$$

(36)

where $\Sigma$ is the unique solution of (27), $D_1 = 60\sqrt{3}/2\alpha$, $a$ is defined in (3), and $q^1(\alpha, \delta)$ in (31).

Proof. The proof follows from Theorem 1, the Portmanteau theorem [21, Theorem 13.16], and the fact that convergence in $W_2$ implies weak convergence. □

Our results is only polynomial in $\delta$ and we cannot expect improving this dependency as illustrated in Example 1 for fixed $\alpha$. The leading term in (36) as $\alpha \downarrow 0$ is $\sqrt{D_1 \{u^\top \Sigma u\}}$. In our next result, we establish a central limit theorem for the family $(\theta_n^{(\alpha)})_{\alpha \in (0, \alpha_{2, \infty})}$, where $\Sigma$ plays the role of the asymptotic covariance matrix. As a result, (36) is a Bernstein-type high probability bound with respect to $\alpha$ and therefore (36) is sharp. Define for any $\alpha \in (0, \alpha_{2, \infty})$,

$$\tilde{\theta}_\infty^{(\alpha)} = \alpha^{-1/2} \{\theta_\infty^{(\alpha)} - \theta^*\}.$$ (37)

Theorem 5. Assume A1. Then, the family $\{\tilde{\theta}_n^{(\alpha)} : \alpha \in (0, \alpha_{2, \infty})\}$ converges in law as $\alpha \downarrow 0$ to a zero-mean Gaussian random variable with covariance matrix $\Sigma$ defined by (27).

Note that this result was established in [28, Theorem 1] for general stochastic approximation schemes but under stronger conditions on the sequence $\{\epsilon_n : n \in \mathbb{N}^+\}$. In particular, it is assumed that the distribution of $\epsilon_1$ admits a density with respect to the Lebesgue measure. We relax this condition and provide a new proof for this result. In particular, our strategy to establish Theorem 5 is to consider the decomposition (21) of $\{\theta_n : n \in \mathbb{N}\}$ with $\theta_0 = 0$, since in such case $\theta_n = \tilde{\theta}_n^{(0)}$ for any $n \in \mathbb{N}$. Define $(J_n^{(\alpha, \leftarrow)} : n \in \mathbb{N}_-)$ by

$$J_n^{(\alpha, \leftarrow)} = \alpha \sum_{k=n}^1 G_{k; 0} \epsilon_{k-1}, \quad G_{k; 0} = \prod_{i=k}^0 (I_d - \alpha A_i).$$

(38)

Note that for any $n \in \mathbb{N}, \theta_n^{(\alpha, \leftarrow)}$ has the same distribution as $\theta_n^{(\alpha)}$ starting from $\theta_0 = 0$ and $J_n^{(\alpha, 0)}$ as $J_{n+1}^{(\alpha, \leftarrow)}$. In contrast to $J_n^{(\alpha, 0)}$, $J_{n+1}^{(\alpha, \leftarrow)}$ admits a limit in $L^2$ and almost surely denoted by $J_n^{(\alpha, \leftarrow)}$.

Then, we get for any $u \in \mathbb{S}^{d-1}, \alpha \in (0, \alpha_{2, \infty})$, bounded and Lipschitz functions $f : \mathbb{R} \to \mathbb{R}$, with Lipschitz constant smaller than $1$, by the Lebesgue dominated convergence theorem

$$\lim_{n \to -\infty} \|f(u^\top \tilde{\theta}_n^{(\alpha, \leftarrow)}) - f(U_n^{(\alpha, 0)})\| = \limsup_{n \to -\infty} \|f(U_n^{(\alpha, 0)}) - f(U_n^{(\alpha, \leftarrow)})\| = 0.$$
Therefore by the Cramer Wold device and the Portmanteau theorem [21, Theorem 13.16], Theorem 5 follows from the next result.

**Proposition 9.** Assume A1. Then, for any $u \in S^{d-1}$, \{\(\alpha^{-1/2}u^T J_{\infty}^{\alpha,\alpha} : \alpha \in (0, \alpha_2, \infty]\) converges in distribution to the zero-mean Gaussian distribution with variance $u^T \Sigma u$ where $\Sigma$ is given in (27).

The proof is postponed to Appendix E.2.

## 6 Conclusion

In this paper, we provided a novel non-asymptotic analysis of LSA algorithms with fixed stepsize. For any $\delta \in (0, 1)$, we obtain bounds on the sequence $\{\|\theta_n - \theta^*\| : n \in \mathbb{N}\}$ that holds with probability at least $1 - \delta$. The bounds are proven to be tight with respect to the stepsize, and we show that these bounds necessarily have polynomial dependency in $\delta$. Importantly, our results do not require the matrices $A_n$ to be symmetric but only Hurwitz, which enables one to apply them to various scenarios such as reinforcement learning. Future work includes extending our high probability bounds to a larger panel of random noise, e.g., with heavy tailed distribution, Markovian dependency, as well as Polyak-Ruppert averaging.

is satisfied for the particular case that we consider. We now show the second statement. Let 
\[ \theta \in \mathbb{R}^{d \times d} \]
noting \[ A \in \mathbb{R}^{d \times d} \]
and \[ (1 - \alpha A)^{-1} \]
that if
\[ \|x\|_2^2 + \alpha^2 \|\bar{A}^\top Q \bar{A}x\|_2^2 \leq 1 - \alpha \|Q\|^{-1} + \alpha^2 \|\bar{A}\|_Q^2 \leq 1 - (1/2)\|Q\|^{-1} \alpha . \]

A Proofs of Section 2

A.1 Proofs of Proposition 1

The existence and uniqueness of \( Q \) follows from [32, Lemma 9.1, p. 140]. Regarding the second statement, note that for any \( x \in \mathbb{R}^d \setminus \{0\} \), we have
\[
\frac{x^\top (I - \alpha A)^\top Q (I - \alpha A)x}{x^\top Q x} = 1 - \alpha \frac{||x||^2}{x^\top Q x} + \alpha^2 \frac{\|\bar{A}^\top Q \bar{A}x\|}{x^\top Q x} .
\]
Hence, we get that for all \( \alpha \in [0, \alpha_\infty] \),
\[
1 - \alpha \frac{||x||^2}{x^\top Q x} + \alpha^2 \frac{\|\bar{A}^\top Q \bar{A}x\|}{x^\top Q x} \leq 1 - \alpha \|Q\|^{-1} + \alpha^2 \|\bar{A}\|_Q^2 \leq 1 - (1/2)\|Q\|^{-1} \alpha .
\]
The proof is completed using that for any matrix \( \bar{A} \in \mathbb{R}^{d \times d} \), \( \|\bar{A}\|_Q \leq \kappa_1^{1/2} \|\bar{A}\| \).

A.2 Proof for Example 1

The existence and uniqueness of the stationary distribution \( \pi_\alpha \) is a consequence of Theorem 3 noting that \( A_1 \) is satisfied for the particular case that we consider. We now show the second statement. Let \( \alpha \in (0, \alpha_2, \infty) \). First, note that since \( B_1 \) is a zero-mean Gaussian random variables with unit variance independent of \( A_1 \), we have for any \( p \geq 1 \),
\[
E[\theta_1^{2p}] = \sum_{k=0}^{2p} \binom{2p}{k} E[\theta_0^{2p-k}] E[(1 - \alpha A_1)^{2(p-k)}] E[b_1^{2k}]
\]
\[
= \sum_{k=0}^{2p} \frac{\binom{2p}{k} E[\theta_0^{2(p-k)}] E[(1 - \alpha A_1)^{2(p-k)}] E[b_1^{2k}]}{E[\theta_0^{2p}] E[(1 - \alpha A_1)^{2p}]} .
\]

This shows that taking \( \theta_0 \) with distribution \( \pi_\alpha \) that if \( \int_{\mathbb{R}} |\theta|^{2p} d\pi_\alpha(\theta) < +\infty \), then it is necessary that \( E[(1 - \alpha A_1)^{2p}] \leq 1 \). However, using that \( E[(1 - \alpha A_1)^{2p}] = \{q_A(1 - \alpha)^{2p} + (1 - q_A)(1 + \alpha)^{2p}\} \) and \( (1 - \alpha)^{2p} \geq 1 - 2\alpha p + (1 + \alpha)^{2p} \geq 1 + 2\alpha p + 2p(2p - 1)\alpha^2 / 2 \), we get for any \( p \geq 1 \),
\[
E[(1 - \alpha A_1)^{2p}] \geq \{1 - 2\alpha(2q_A - 1) - (2p - 1)\alpha(1 - q_A)/2\},
\]
therefore \( E[(1 - \alpha A_1)^{2p}] \leq 1 \) does not hold for \( 2p > \bar{p}_{q_0, 1} = 1 + 2(2q_A - 1)/\alpha(1 - q_A) \).

B Technical and supporting results for Section 3

Proposition 10 ([17, Proposition 4.3]). Consider two random matrices \( X, Y \in \mathbb{R}^{d \times d} \) that satisfy
\[
E[Y | X] = 0. Then for \( 2 \leq q \leq p \),
\[
\|X + Y\|_{p,q}^2 \leq \|X\|_{p,q}^2 + C_p \|Y\|_{p,q}^2 ,
\]
where \( C_p = p - 1 \).
Lemma 1. Let \( A \in \mathbb{R}, B > 0, C \geq 1, p_0, p_1 \in \mathbb{R} \) such that 1 \( \leq p_0 \leq p_1 < +\infty \), and \( X \) a real random variable satisfying, for any \( p \in [p_0, p_1] \),

\[
\mathbb{E}[|X|^p] \leq C \exp(-Ap + Bp^2).
\]

Then, for all \( \delta \in (0, 1] \), we have, with probability at least \( 1 - \delta \),

\[
|X| \leq \exp \left( -A + Bp_0 + 2\sqrt{B \log(C/\delta) + \log(C/\delta)/p_1} \right),
\]

with the convention \( c/\infty = 0 \) for \( c > 0 \). In addition if (39) is satisfied for any \( p \geq p_0 \), then with probability at least \( 1 - \delta \),

\[
|X| \leq \exp \left( -A + Bp_0 + 2\sqrt{B \log(C/\delta)} \right).
\]

**Proof.** Note that by the monotone convergence theorem, it is sufficient to show (39). By Markov’s inequality, we have, for any \( t > 0 \) and \( p \in [p_0, p_1] \),

\[
P(|X| \geq t) \leq \mathbb{E}[|X|^p]/t^p \leq C \exp \left( -p(\log(t) + A - Bp) \right).
\]

Taking \( t = \exp(-A + 2Ba^*) \) for \( a^* \in \mathbb{R} \) and maximizing over \( p \in [p_0, p_1] \), we obtain

\[
P(|X| \geq \exp(-A + 2Ba^*)) \leq C \exp \left( -Bp(2a^* - p) \right) \leq C \exp \left( -B\phi(a^*) \right),
\]

where

\[
\phi(a^*) = \max_{p \in [p_0, p_1]} p(2a^* - p) = (2p_0a^* - p_0^2) \mathbb{1}_{(-\infty, p_0]}(a^*) + (a^*)^2 \mathbb{1}_{(p_0, p_1]}(a^*) + (2p_1a^* - p_1^2) \mathbb{1}_{[p_1, +\infty)}(a^*).
\]

Note that for any \( t \in \mathbb{R} \), the inverse of \( \phi \) is given by

\[
\phi^{-1}(t) = \frac{p_0^2 + t}{2p_0} \mathbb{1}_{(-\infty, p_0]}(t) + t^{1/2} \mathbb{1}_{(p_0, p_1]}(t) + \frac{p_1^2 + t}{2p_1} \mathbb{1}_{[p_1, +\infty)}(t).
\]

For \( \delta > 0 \), taking \( a_\delta^* = \phi^{-1}(\log(C/\delta)/B) \) gives

\[
P(|X| \geq \exp[-A + 2B\phi^{-1}(\log(C/\delta)/B)]) \leq \delta.
\]

The proof then follows from the fact that for any \( t \in \mathbb{R} \), \( \phi^{-1}(t) \leq p_0/2 + \sqrt{t} + t/(2p_1) \). \( \square \)

**Proof of (18) and (19)**

Let \( \alpha \in (0, \bar{\alpha}_q) \). Note that by definition of \( \{\theta_n : n \in \mathbb{N}\} \) with (4), for any \( n \in \mathbb{N} \),

\[
\theta_n = (1 - \alpha)^{N_n} (1 + \alpha)^{n - N_n}, \quad \text{where} \quad N_n = \sum_{k=1}^{n} \mathbb{1}_{\{1\}}(Z_k).
\]

Then, for any \( \beta > 0 \), we get

\[
P(\theta_n \geq e^{-\alpha\beta n}) = P(\log(\theta_n) \geq -\alpha\beta n) = P\left(N_n \log \left( \frac{1 - \alpha}{1 + \alpha} \right) \geq -\alpha\beta n - n \log(1 + \alpha) \right)
\]

\[
= P\left(N_n \leq n \log^{-1} \left( \frac{1 + \alpha}{1 - \alpha} \right) \{\alpha\beta + \log(1 + \alpha)\} \right)
\]

\[
= P\left(N_n - q_A n \leq -n \left[ q_A - \log^{-1} \left( \frac{1 + \alpha}{1 - \alpha} \right) \{\alpha\beta + \log(1 + \alpha)\} \right] \right). \quad (43)
\]

Let \( \beta_{\alpha,q} = \alpha^{-1} [q_A \log \{(1 + \alpha)/(1 - \alpha)\} - \log(1 + \alpha)] \). Note that with the condition, \( \alpha \in (0, \bar{\alpha}_q) \), \( \beta_{\alpha,q} > 0 \) and therefore for any \( \beta \in (0, \beta_{\alpha,q}) \),

\[
x_{\alpha,\beta} = [q_A - \log^{-1} \left( \frac{1 + \alpha}{1 - \alpha} \right) \{\alpha\beta + \log(1 + \alpha)\}] \in (0, \bar{\varphi}_q(\alpha) \), \quad (44)
\]

We now show (18). From (43), it follows using Hoeffding’s inequality that for any \( \beta \in (0, \beta_{\alpha,q}) \),

\[
P(\theta_n \geq e^{-\alpha\beta n}) \leq e^{-2nx_{\alpha,\beta}^2}. \quad (45)
\]
Hence, for \( \delta \in (e^{-2n\tilde{z}_2^{\varphi_q}(\alpha)}, 1) \), there exists \( x \in (0, \varphi_q(\alpha)) \) such that \( e^{-2nx^2} = \delta \) given by \( x = \sqrt{\log(1/\delta)/2n} \), which corresponds by (44) to

\[
\beta = \alpha^{-1} \left\{ q_A - \sqrt{\log(1/\delta)/(2n)} \right\} \log \left( \frac{1 + \alpha}{1 - \alpha} \right) - \alpha^{-1} \log(1 + \alpha) \in (0, \beta_{\alpha,q}) .
\]

This completes the proof of (18) using (45).

We now show (19). Using [1, Lemma 4.7.2] and (43), it holds that for any \( \beta \in (0, \beta_{\alpha,q}) \),

\[
\mathbb{P} \left( \theta_n \geq e^{-\alpha \beta n} \right) \geq \exp(-n\text{KL}(q_A - x_{\alpha,\beta} | q_A) - 2^{-1} \log(n)) ,
\]

where for any \( \tilde{q} \in (0, 1) \),

\[
\text{KL}(\tilde{q} | q_A) = \tilde{q} \log(\tilde{q} / q_A) + (1 - \tilde{q}) \log((1 - \tilde{q}) / (1 - q_A)) .
\]

Note that for any \( \tilde{q} \in (0, 1) \), \( \tilde{q} \leq q_A \), using \( \log(1 + t) \leq t \) for any \( t > -1 \), we get

\[
\text{KL}(\tilde{q} | q_A) \leq (q_A - \tilde{q})^2 / (q_A(1 - q_A)) .
\]

Therefore, plugging this result into (46) yields for any \( \beta \in (0, \beta_{\alpha,q}) \),

\[
\mathbb{P} \left( \theta_n \geq e^{-\alpha \beta n} \right) \geq \exp(-nx_{\alpha,\beta}^2 / (q_A(1 - q_A)) - 2^{-1} \log(n)) .
\]

Hence, for \( \tilde{q} \in (e^{-n x_{\alpha,q}^2(\alpha)/(n(1-q_A))} - 2^{-1} \log(n), 1) \) there exists \( x \in (0, \varphi_q(\alpha)) \) such that \( e^{-nx^2/(n(1-q_A))} - 2^{-1} \log(n) = \delta \), given by \( x = \sqrt{2^{-1} \log(n) + q_A(1 - q_A) \log(1/\delta)/n} \), which corresponds by (44) to

\[
\beta = \alpha^{-1} \left\{ q_A - \sqrt{-2^{-1} \log(n) + q_A(1 - q_A) \log(1/\delta)/n} \right\} \log \left( \frac{1 + \alpha}{1 - \alpha} \right) - \alpha^{-1} \log(1 + \alpha) .
\]

This completes the proof of (19) using (47).

Proof of Proposition 3. It suffices to repeat the argument of Corollary 1. We need a version of Proposition 2 for the product \( Z_n = \prod_{\ell \in \mathbb{N}} Y_{\ell} \) where \( \{ Y_{\ell} : \ell \in \mathbb{N} \} \) are an independent and for each \( \ell, q \in \mathbb{N} \) there exist \( m_{\ell} \in (0, 1) \) and \( \sigma_{\ell,q} > 0 \) such that \( \| E[Y_{\ell}] \|_{q}^2 \leq 1 - m_{\ell} \) and \( E^{1/q} \| Y_{\ell} - E[Y_{\ell}] \|_{q}^q \leq \sigma_{\ell,q} \). We use notations of \( A_n, B_n \) from Proposition 2. Applying independence of \( Z_n \) and \( Y_n \) and \( E^{1/q} \| Y_{\ell} - E[Y_{\ell}] \|_{q}^q \leq \sigma_{\ell,q} \) we estimate

\[
\| A_n \|_{p,q} \leq \left( E \left[ \| Y_n - E[Y_n] \|_{q}^q \| f_Q(Z_{n-1}) \|_{p}^2 \right] \right)^{1/q} \leq \sigma_{n,q} \| f_Q(Z_{n-1}) \|_{p,q}. \tag{48}
\]

The bound for \( \| B_n \|_{p,q}^2 \) remains the same: \( \| B_n \|_{p,q}^2 \leq (1 - m_n) \| f_Q(Z_{n-1}) \|_{p,q}^2 \). Combining this inequality with (48) and (10) yields for any \( n \in \mathbb{N}^* \), \( \| f_Q(Z_n) \|_{p,q}^2 \leq (1 - m_n + (p - 1) \sigma_{n,q}^2) \| f_Q(Z_{n-1}) \|_{p,q}^2 \). The proof is then completed upon using (11) which implies that \( \| Z_n \|_{p,q} = \| Q^{-1/2} f_Q(Z_n) Q^{1/2} \|_{p,q} \leq \sqrt{\kappa_Q} \| f_Q(Z_n) \|_{p,q} \). Finally, it remains take \( Y_{\ell} = 1 - \alpha A_\ell, \ell \geq 1, Y_0 = 1 \). As \(-A\) is Hurwitz, applying Proposition 1 yields \( \| E[Y_{\ell}] \|_{q}^q = 1 - \alpha \| A_\ell \|_{q}^q \leq 1 - \alpha \| A \|_{q}^q \). Further, since \( \| A - \bar{A} \| \in \text{SG}(C_A) \) we get by Lemma 3

\[
E^{1/q} [ \| Y_{\ell} - E[Y_{\ell}] \|_{q}^q ] = \alpha E^{1/q} [ \| A_\ell - \bar{A} \|_{q}^q ] \leq 2\alpha \sqrt{\kappa_Q} C_A^\prime = \alpha b_Q \sqrt{\kappa_Q} .
\]

Taking \( m_{\ell} = \alpha \) and \( \sigma_{\ell,q} = b_Q \alpha \sqrt{\kappa_Q} \) we get the claim of the proposition.

\( \square \)

C Proofs of Section 4

For ease of presentation, we drop in this section the dependence of \( J_n^{(\alpha,0)}, H_n^{(\alpha,0)}, J_n^{(\alpha,1)}, H_n^{(\alpha,1)} \) with respect to \( \alpha \) and simply write \( J_n^{(0)}, H_n^{(0)}, J_n^{(1)}, H_n^{(1)} \), respectively. We denote \( A_n = A_n - \bar{A} \).
C.1 Proof of Proposition 4

Let \( n \in \mathbb{N}^* \), \( \alpha \in (0, \alpha_{p_0, \infty}] \), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1) \). Under A1, applying Corollary 2 with \( p = p_0 \) yields

\[
\mathbb{E}^{1/p_0}[[u^T \Gamma_1^{(\alpha)}(\theta_0 - \theta^*)][p_0]] \leq \mathbb{E}^{1/p_0}[[\Gamma_1^{(\alpha)}][p_0]][\theta_0 - \theta^*] \leq \sqrt{n}Qd^{1/p_0}(1 - a\alpha + (p_0 - 1)\beta_2^2\alpha^2)\|\theta_0 - \theta^*\|.
\]

Since \( \alpha \leq a/(2\beta_2^2(p_0 - 1)) \), using \( (1 - t)^{1/2} \leq 1 - t/2 \) for \( t \in [0, 1] \), we get

\[
\mathbb{E}^{1/p_0}[[u^T \Gamma_1^{(\alpha)}(\tilde{\theta})][p_0]] \leq \sqrt{n}Qd^{1/p_0}[\theta_0 - \theta^*](1 - a\alpha/4)^n.
\]

Applying Markov’s inequality easily completes the proof.

C.2 Proof of Proposition 5

Let \( n \in \mathbb{N}^* \), \( \alpha \in (0, \alpha_{p_0, \infty}] \), \( u \in \mathbb{S}^{d-1} \) and \( \delta \in (0, 1) \). Using (22) and applying Rosenthal’s inequality [30, Theorem 4.1] for sum of centered independent random variables we get for any \( p \geq 2 \),

\[
\mathbb{E}[[u^T J_n^{(\alpha)}][p]] \leq (60e)^p/p^{p/2}\{u^T \Sigma_\alpha u\}^{p/2} + \alpha^p60^p\mathbb{P}\left[\max_{\ell=1,\ldots,n} |u^T G_{\ell+1:n}\varepsilon_\ell|p\right].
\]

Applying Lemma 5, we obtain for any \( p \geq 2 \),

\[
\mathbb{E}[[u^T J_n^{(\alpha)}][p]] \leq (60e)^p/p^{p/2}\{u^T \Sigma_\alpha u\}^{p/2} + (9\{1 + \log[1/(\alpha\alpha)]\}K_\alpha C_e^2n^{p/2}\alpha^p60^p\mathbb{P}\left[\varepsilon_\ell\right]^{3p/2}, (49)
\]

where the constant \( C_e \) is given in (63). Applying Markov’s inequality, we get for any \( p \geq 2 \), \( c_1, c_2 > 0 \),

\[
\mathbb{P}(|u^T J_n^{(\alpha)}| > c_1\{u^T \Sigma_\alpha u\}^{1/2} + c_2) \leq c_1\{u^T \Sigma_\alpha u\}^{-1/2}c_2^{-p}\left[(60e)^p/p^{p/2}\{u^T \Sigma_\alpha u\}^{p/2} + (9\{1 + \log[1/(\alpha\alpha)]\}K_\alpha C_e^2n^{p/2}\alpha^p60^p\mathbb{P}\left[\varepsilon_\ell\right]^{3p/2}\right]
\]

where

\[
D_1 = 60\sqrt{3}e^{4/3}, \quad D_2 = 540\sqrt{3}e^{1/3}K_\alpha C_e^{1/2}.
\]

C.3 Proof of Proposition 6

Lemma 2. Assume that A1-(iii) holds. Then, for any \( \alpha \in (0, \alpha_{\infty}) \), where \( \alpha_{\infty} \) is defined in (3),

\[
||\Sigma^\alpha - \Sigma||_Q \leq \alpha^{-1}||\bar{A}\Sigma\bar{A}^T||_Q,
\]

where \( \Sigma^\alpha \) and \( \Sigma \) are defined in (25) and (27) respectively and \( \alpha \) is given in (3).

Proof. Let \( \alpha \in (0, \alpha_{\infty}) \). By definition, (25) and (27) imply

\[
\bar{A}(\Sigma^\alpha - \Sigma) + (\Sigma^\alpha - \Sigma)\bar{A}^T - \alpha\bar{A}(\Sigma^\alpha - \Sigma)\bar{A}^T = \alpha\bar{A}\Sigma\bar{A}^T,
\]

which writes

\[
\Sigma^\alpha - \bar{\Sigma} - (\alpha-\alpha\bar{A})(\Sigma^\alpha - \Sigma)(I-\alpha\bar{A})^T = \alpha^2\bar{A}\Sigma\bar{A}^T.
\]

This implies, by Proposition 1,

\[
||\Sigma^\alpha - \Sigma||_Q \leq \sqrt{(1 - \alpha\alpha)||\Sigma - \Sigma||_Q + \alpha^2||\bar{A}\Sigma\bar{A}^T||_Q},
\]

Rearranging terms completes the proof.

\[\square\]

Note that the specific universal constants \( C_{R,1} = 60e \) and \( C_{R,2} = 60 \) are not given in the statement, but a close inspection of the proof provide the given estimates.
C.4 Proof of Proposition 7

Proposition 7 is a direct consequence of the following statements.

**Proposition 11.** Assume A1. Then, for any $n \in \mathbb{N}$, $\alpha \in (0, \alpha_{\infty})$, where $\alpha_{p_0, \infty}$ is defined in (16), $u \in \mathbb{S}^{d-1}$ and $p \geq 2$,

$$
\mathbb{E}[|u^T J_n^{(1)}|^p] \leq D_3^p \alpha^p p^{2p},
$$

where $D_3$ is given in (58). Moreover, for any $\delta \in (0, 1)$ with probability at least $1 - \delta$,

$$
|u^T J_n^{(1)}| \leq eD_3 \alpha \log^2 (1/\delta).
$$

**Proposition 12.** Assume A1 and let $p_0 \geq 2$. Then, for any $n \in \mathbb{N}$, $\alpha \in (0, \alpha_{p_0, \infty})$, where $\alpha_{p_0, \infty}$ is defined in (16), $u \in \mathbb{S}^{d-1}$,

$$
\mathbb{E}[|u^T H_n^{(1)}|^p] \leq D_4^p \alpha^{p_0} p_0^{2p_0},
$$

where $D_4$ is given in (61). Moreover, for any $\delta \in (0, 1)$ with probability at least $1 - \delta$,

$$
|u^T H_n^{(1)}| \leq D_4 \alpha p_0^{2} \delta^{-1/p_0}.
$$

**Proof of Proposition 11.** First, we note that (28) implies

$$
J_n^{(1)} = \alpha^2 \sum_{\ell=1}^{n-1} S_{\ell+1:n} \epsilon_{\ell}, \quad \text{with} \quad S_{\ell+1:n} = \sum_{k=1}^{n} (I - \alpha \tilde{A})^{n-k-1} \tilde{A}_k (I - \alpha \tilde{A})^{k-1-\ell}.
$$

It is easy to check that the sequence $(\alpha^2 S_{\ell+1:n} \epsilon_{\ell}, \tilde{F}_{\ell+1:n})_{\ell=1}^{n-1}$ is a martingale-difference, where $
\tilde{F}_{\ell+1:n} = \sigma \left( (A_j, b_j)_{j \in \{\ell+1, \ldots, n\}} \right)$. We may use Burkholder’s inequality [15, Theorem 2.10] to get

$$
\mathbb{E}[|u^T J_n^{(1)}|^p] \leq (36p)^p \alpha^{2p} \mathbb{E} \left[ \left( \sum_{\ell=1}^{n-1} (u^T S_{\ell+1:n} \epsilon_{\ell})^2 \right)^{p/2} \right].
$$

Using the Minkowski inequality,

$$
\mathbb{E}[|u^T J_n^{(1)}|^p] \leq (36p)^p \alpha^{2p} \left( \sum_{\ell=1}^{n-1} \mathbb{E}^{2/p} (|u^T S_{\ell+1:n} \epsilon_{\ell}|)^p \right)^{p/2}.
$$

Denote $V_{\ell+1} = u^T S_{\ell+1:n}$. Note that by Assumption A1-(ii) and Lemma 1, $(I - \alpha \tilde{A})^{n-k-1} \tilde{A}_k (I - \alpha \tilde{A})^{k-1-\ell} \leq \kappa_Q C_A (1 - \alpha a)^{(n-\ell-2)/2}$. Applying [29, Theorem 3][3], we get for any $t \geq 0$

$$
\mathbb{P}(\|V_{t+1}\| \geq t) \leq 2 \exp \left\{ -t^2 / (2\kappa_Q^2 C_A^2 (n - \ell)(1 - \alpha a)^{(n-\ell-2)/2}) \right\}.
$$

Using Lemma 3,

$$
\mathbb{E}^{2/p} (|V_{t+1}|)^p \leq 2 \sqrt{2} C_A \kappa_Q^2 (n - \ell)(1 - \alpha a)^{(n-\ell-2)/2}.
$$

Since $S_{\ell+1:n}$ and $\epsilon_{\ell}$ are independent,

$$
\mathbb{E}[|u^T S_{\ell+1:n} \epsilon_{\ell}|] \leq \mathbb{E}[\|V_{t+1}\|] \sup_{u \in \mathbb{S}^{d-1}} \mathbb{E}[|u^T \epsilon_{\ell}|].
$$

Assumption A1-(i), Lemma 3 and Lemma 5 imply, that for any $u \in \mathbb{S}^{d-1},$

$$
\mathbb{E}[|u^T \epsilon_{\ell}|] \leq p^{p/2} C_{\ell} (2\sqrt{2})^{p/2}.
$$

Combining this bound with (57),

$$
\mathbb{E}[|u^T S_{\ell+1:n} \epsilon_{\ell}|] \leq p^{p/2} C_{\ell} \kappa_Q^2 C_A \kappa_Q^2 (n - \ell)^{p/2} (1 - \alpha a)^{(n-\ell-2)/2}.
$$

This inequality and (56) imply

$$
\mathbb{E}[|u^T J_n^{(1)}|^p] \leq \alpha^{2p} (72\sqrt{2})^{p} C_A \kappa_Q^p C_{\ell} \left( \sum_{\ell=1}^{n-1} (n - \ell)(1 - \alpha a)^{(n-\ell-2)/2} \right)^{p/2}
$$

$$
\leq \alpha^{p} D_3 \alpha^{p} D_2^{2p}, \quad \text{where} \quad D_3 = (72\sqrt{2}) C_A \kappa_Q C_{\ell} a^{-1}(1 - \alpha a_{\infty})^{-1}.
$$

\[3\] with $\mathcal{X} = \mathbb{R}^d$ equipped with the Euclidean norm $\| \cdot \|$. Note that $\|x\|, x \in \mathbb{R}^d$ is twice Gateaux differentiable and $\mathcal{X} \in D(A_1, A_2)$ with $A_1 = A_2 = 1$. 

16
Now the equation (29) follows from Markov’s inequality. Namely, for any $c_1 > 0$ it holds
\[
P \left( |u^\top J_n^{(1)}| \geq c_1 \alpha D_3 \right) \leq \frac{\alpha D_3 p^2 \beta^2}{c_1^2 \alpha^p D_3^2} = c_1^{-p} p^2.
\]
Taking $p = \log (1/\delta)$ and $c_1 = e \log^2 (1/\delta)$, we obtain (29).

**Proof of Proposition 12.** With the decomposition (28), we represent
\[
u^\top H_n^{(1)} = -\alpha \sum_{\ell=1}^n u^\top \Gamma^{(\alpha)}_{\ell+1:\infty} \tilde{A}_\ell J_{\ell-1}^{(1)}.
\]
Using Minkowski’s inequality,
\[
\mathbb{E}^{1/p} \left[ |u^\top H_n^{(1)}|^p \right] \leq \alpha \sum_{\ell=1}^n \mathbb{E}^{1/p} \left[ |u^\top \Gamma^{(\alpha)}_{\ell+1:\infty} \tilde{A}_\ell J_{\ell-1}^{(1)}|^p \right] .
\]
Now, using the independence of $\Gamma^{(\alpha)}_{\ell+1:\infty}$, $\tilde{A}_\ell$, $J_{\ell-1}^{(1)}$, and Item (ii),
\[
\mathbb{E}^{1/p} \left[ |u^\top \Gamma^{(\alpha)}_{\ell+1:\infty} \tilde{A}_\ell J_{\ell-1}^{(1)}|^p \right] \leq \mathbb{E}^{1/p} \left[ |u^\top \Gamma^{(\alpha)}_{\ell+1:\infty} \tilde{A}_\ell|^p \right] \sup_{v \in \mathbb{S}^{d-1}} \mathbb{E}^{1/p} \left[ |u^\top J_{\ell-1}^{(1)}|^p \right]
\]
\[
\leq 2 C_A \mathbb{E}^{1/p} \left[ ||\Gamma^{(\alpha)}_{\ell+1:\infty}||^p \right] \sup_{v \in \mathbb{S}^{d-1}} \mathbb{E}^{1/p} \left[ |u^\top J_{\ell-1}^{(1)}|^p \right].
\]
Hence, applying Corollary 2 to $\mathbb{E}^{1/p} ||\Gamma^{(\alpha)}_{\ell+1:\infty}||^p$, and (59) to $\sup_{v \in \mathbb{S}^{d-1}} \mathbb{E}^{1/p} ||u^\top J_{\ell-1}^{(1)}||^p$,
\[
\mathbb{E}^{1/p} \left[ |u^\top H_n^{(1)}|^p \right] \leq 2 C_A \sqrt{\kappa_Q d^{1/p} D_3} \alpha^2 \beta^2 \sum_{\ell=1}^n (1 - \alpha \alpha + (p - 1) b_0^2 \alpha^2)^{(n-\ell)/2}.
\]
Since $p_0 - 1 \leq a/(2b_0^2 \alpha)$, from the previous estimate it follows
\[
\mathbb{E}^{1/p_0} \left[ |u^\top H_n^{(1)}|^p_0 \right] \leq 2 C_A \sqrt{\kappa_Q d^{1/p_0} D_3} \alpha^2 \beta^2 \sum_{\ell=1}^n (1 - \alpha a)^{(n-\ell)/2}
\]
\[
\leq 4 C_A \sqrt{\kappa_Q d^{1/p_0} D_3} \alpha^2 \beta^2 / a.
\]
Hence,
\[
\mathbb{E} \left[ |u^\top H_n^{(1)}|^p_0 \right] \leq D_4^p \alpha^2 \beta^2 / \delta^{p_0}, \text{ where } D_4 = 4 C_A \sqrt{\kappa_Q d^{1/p_0} D_3} / a.
\]
Using Markov’s inequality, we get with probability at least $1 - \delta$,
\[
|u^\top H_n^{(1)}| \leq D_4 \alpha^2 \beta^2 / \delta^{p_0}.
\]

**C.5 Proof of Proposition 8**

The proof is along the same lines as the proof of $H_n^{(1)}$ in Appendix C.A, with the better bound for $\mathbb{E}^{1/p} ||\Gamma^{(\alpha)}_{\ell+1:n}||^p$. For reader’s convenience, we provide the proof below. Starting with equation (60), we note that under A2,
\[
\mathbb{E}^{1/p} ||\Gamma^{(\alpha)}_{\ell+1:n}||^p \leq \sqrt{\kappa_Q} (1 - \alpha \hat{\alpha})^{n-\ell}.
\]
We also apply (59) to $\sup_{v \in \mathbb{S}^{d-1}} \mathbb{E}^{1/p} ||u^\top J_{\ell-1}^{(1)}||^p$. Then
\[
\mathbb{E}^{1/p} \left[ |u^\top H_n^{(1)}|^p \right] \leq 2 \sqrt{\kappa_Q} C_A D_3 \alpha^2 \beta^2 \sum_{\ell=1}^n (1 - \alpha \hat{\alpha})^{n-\ell} \leq D_5 \alpha^2 \beta^2,
\]
where we have defined
\[
D_5 = 2 \sqrt{\kappa_Q} C_A D_3 / \alpha.
\]
Now the equation (32) follows from Markov’s inequality.
D Concentration results for sub-Gaussian random variables

Lemma 3. Random variable \( X \in \text{SG}(\sigma^2) \) for some \( \sigma > 0 \) if and only if for all \( t \geq 0 \) the condition \( \mathbb{P}(|X| \geq t) \leq 2 \exp(-t^2/(2\sigma^2)) \) holds. In addition, in such a case, for any \( p \geq 2 \), we have
\[
\mathbb{E}[|X|^p] \leq \sqrt{2}\varepsilon(2/e)^{p/2}p^{p/2}\sigma^p.
\]

Proof. The first statement is well-known, see for example [8, Theorem 2.1]. We now show the second statement. By the Fubini theorem, \( \mathbb{E}[|X|^p] = p \int_0^{+\infty} u^{p-1} \mathbb{P}(|X| > u) \, du \), we get
\[
\mathbb{E}[|X|^p] = 2p \int_0^{+\infty} u^{p-1} e^{-u^2/(2\sigma^2)} \, du = p2^{p/2}\sigma^p\Gamma(p/2),
\]
using the change of variable \( t = u^2/(2\sigma^2) \). Now, using an upper bound \( \Gamma(p/2) \leq (p/2)^{(p-1)/2}e^{1-p/2} \) (see e.g. [14, Theorem 2]), and \( p^{1/2} \leq 2p^{1/2} \), we finally get
\[
\mathbb{E}[|X|^p] \leq \sqrt{2}\varepsilon(2/e)^{p/2}p^{p/2}\sigma^p.
\]
\( \square \)

Lemma 4. Let \( \{X_\ell : \ell \in \mathbb{N}\} \) be a sequence of random variables such that \( X_\ell \in \text{SG}(\sigma^2) \) for any \( \ell \in \mathbb{N} \) and some \( \sigma^2 > 0 \). Then for any \( p \geq 2 \),
\[
\mathbb{E} \left[ \max_{\ell=1, \ldots, n} \left( |X_\ell|/\sqrt{1 + \log \ell} \right)^p \right] \leq 3^{p\sigma^p} p^{p/2}.
\]

Proof. Set \( a_k = (1 + \log k)^{1/2} \) for \( k \in \mathbb{N}^* \). Using the Fubini’s theorem, \( \mathbb{E}[|\xi|^p] = p \int_0^{+\infty} u^{p-1} \mathbb{P}(|\xi| > u) \, du \), the union bound, and Lemma 3, we get
\[
\mathbb{E} \left[ \max_{k=1, \ldots, n} \left\{ |X_k|^p/a_k^p \right\} \right] = p \int_0^{+\infty} u^{p-1} \mathbb{P} \left( \max_{k=1, \ldots, n} |X_k| \geq ua_k \right) \, du
\leq 2^{p\sigma^p} + p \int_{2\sigma}^{+\infty} u^{p-1} \mathbb{P} \left( \max_{k=1, \ldots, n} |X_k| \geq ua_k \right) \, du
\leq 2^{p\sigma^p} + p \int_{2\sigma}^{+\infty} u^{p-1} \sum_{k=1}^n \mathbb{P}(|X_k| \geq ua_k) \, du
\leq 2^{p\sigma^p} + p \int_{2\sigma}^{+\infty} u^{p-1} \sum_{k=1}^n \exp \left( -u^2 a_k^2/(2\sigma^2) \right) \, du
\leq 2^{p\sigma^p} + 2\pi^2 p\sigma^p \int_2^{+\infty} y^{p-1} \exp \left( -y^2/2 \right) \left( \sum_{k=1}^n k^{-y^2/2} \right) \, dy
\leq 2^{p\sigma^p} + \frac{\pi^2 p\sigma^p}{3} \int_2^{+\infty} y^{p-1} \exp \left( -y^2/2 \right) \, dy \leq 2^{p\sigma^p} + \frac{\pi^2 p\sigma^p 2^{p/2-1}}{3} \Gamma(p/2).
\]
Using \( \Gamma(p/2) \leq (p/2)^{(p-1)/2}e^{1-p/2} \) (see [14, Theorem 2]), we get
\[
\mathbb{E} \left[ \max_{k=1, \ldots, n} \left\{ |X_k|^p/a_k^p \right\} \right] \leq 2^{p\sigma^p} + \pi^2 p\sigma^p p^{p+1/2} e^{1-p/2}/(3\sqrt{2}).
\]
Since \( \sqrt{\pi} e^{-p/2} \leq e^{-1/2} \) and \( 2^p \leq 4p^{1/2} \),
\[
\mathbb{E} \left[ \max_{k=1, \ldots, n} \left\{ |X_k|^p/a_k^p \right\} \right] \leq \sigma^p p^{p/2} \left( 4 + \pi^2 e^{1/2}/(3\sqrt{2}) \right) < 9\sigma^p p^{p/2}.
\]
\( \square \)

Lemma 5. Assume A1. Then, for any \( n \in \mathbb{N}^* \) and \( v \in \mathbb{S}^{d-1}, v^\top \varepsilon_n \) defined by (7) is a sub-Gaussian random variable with parameter
\[
C_v^2 = 2C_0^2 + 8C_A^2 \|\theta^*\|^2.
\]
In addition, for any \( n \in \mathbb{N}^* \), \( p \geq 2 \), \( u \in \mathbb{S}^{d-1} \) and \( \alpha \in (0, \alpha_\infty) \), it holds
\[
E \left[ \max_{\ell=1,\ldots,n} |u^T G_{\ell+1:n}^{(\alpha)} \varepsilon_\ell|^p \right] \leq (9\kappa_Q p C_\varepsilon^2 \{1 + \log[1/(\alpha \theta)]\})^{p/2},
\]
where \( \alpha_\infty \), \( \alpha \) and \( \kappa_Q \) are defined in (3).

**Proof.** First we prove (63). Using the representation (7), for any \( \lambda \in \mathbb{R} \),
\[
E[\exp \{ \lambda u^T \varepsilon_n \}] \leq E[\exp \{ \lambda u^T (\omega_n - \bar{b} - \{ \omega_n - \bar{A} \} \theta^*) \}] \\
\leq \mathbb{E}^{1/2}[\exp \{ 2\lambda u^T (\omega_n - \bar{b}) \}] E^{1/2}[\exp \{ 2\lambda v^T (\bar{A} - \omega_n) \theta^* \}] .
\]

Note that A1-(ii) implies \( |v^T (\bar{A} - \omega_n) \theta^*| \leq 2 C_A \| \theta^* \| \). Hence, using the Hoeffding inequality, \( v^T (\bar{A} - \omega_n) \theta^* \in \text{SG}(4 C_A^2 \| \theta^* \|^2) \). Combining this result with A1-(i),
\[
E[\exp \{ \lambda v^T \varepsilon_n \}] \leq \exp \{ \lambda^2 C_\varepsilon^2 \} \exp \left\{ 4\lambda^2 C_A^2 \| \theta^* \|^2 \right\} ,
\]
yielding the first statement of the lemma.

To prove the second part, let us denote \( v_\ell = ((1 - \alpha \bar{A})^{-\ell} u/((1 - \alpha \bar{A})^{-\ell} u) \in \mathbb{S}^{d-1} \). Using Proposition 1,
\[
E[\max_{\ell=1,\ldots,n} |u^T G_{\ell+1:n}^{(\alpha)} \varepsilon_\ell|^p] = E[\max_{\ell=1,\ldots,n} |v_\ell^T \varepsilon_\ell|^p \| G_{\ell+1:n}^{(\alpha)} u \|^p] \\
\leq \kappa_Q^{p/2} E[\max_{\ell=1,\ldots,n} |v_\ell^T \varepsilon_\ell|^p (1 - \alpha a)^{(n-\ell)/2]} \\
\leq \kappa_Q^{p/2} E \left[ \max_{\ell=1,\ldots,n} \frac{|v_\ell^T \varepsilon_\ell|^p}{(1 + \log (n - \ell + 1))^{p/2}} \right] \left\{ \max_{x>0} (1 + \log(x + 1)) e^{-ax} \right\}^{p/2} \\
\leq \kappa_Q^{p/2} (9 C_\varepsilon^2 p)^{p/2} \left\{ \max_{x>0} (1 + \log(x + 1)) e^{-ax} \right\}^{p/2},
\]
where in the last inequality we used Lemma 4. Set \( f(x) = (1 + \log(x + 1)) e^{-cx} \) with \( c = a\alpha \leq 1 \) over \( x > 0 \). First, note that \( f'(x) = e^{-cx}(1/(1 + x) - c e \log(x + 1)) < 0 \) for all \( x > c^{-1} - 1 \), and thus the maximum is attained for \( x \in [0, 1/c - 1] \). Moreover, for any \( x \leq 1/c - 1 \), we have \( f(x) \leq 1 + \log(1 + x) \leq 1 + \log(1/c) \), leading to the desired result. \( \square \)

**E  Proof of Section 5**

**E.1 Proof of Theorem 3**

Let \( \alpha \in (0, \alpha_2, \infty) \) and \( \lambda_1, \lambda_2 \in \mathbb{P}_2(\mathbb{R}^d) \). By [37, Theorem 4.1], there exists a couple of random variables \( \theta_0^{(1)}, \theta_0^{(2)} \) such that \( W_2(\lambda_1, \lambda_2) = E[\| \theta_0^{(1)} - \theta_0^{(2)} \|^2] \) independent of \( \{(\omega_n, b_n) : n \in \mathbb{N}^* \} \). We introduce then a synchronous coupling between \( \lambda_1 R_0^n \) and \( \lambda_2 R_0^n \) as follows. Let \( \{(\theta_n^{(1)}, \theta_n^{(2)}) : n \in \mathbb{N}\} \) starting from \( \theta_0^{(1)} \) and \( \theta_0^{(2)} \) respectively and for all \( n \geq 0 \),
\[
\theta_{n+1}^{(1)} = (1 - \alpha A_{n+1}) \theta_{n+1}^{(1)} + \alpha b_{n+1} \\
\theta_{n+1}^{(2)} = (1 - \alpha A_{n+1}) \theta_{n+1}^{(2)} + \alpha b_{n+1} .
\]

Since for all \( n \geq 0 \), the distribution of \( (\theta_n^{(1)}, \theta_n^{(2)}) \) belongs to \( \Pi(\lambda_1 R_0^n, \lambda_2 R_0^n) \), by definition of the Wasserstein distance we get for any \( n \in \mathbb{N} \),
\[
W_2(\lambda_1 R_0^n, \lambda_2 R_0^n) \leq E^{1/2}[\| \theta_n^{(1)} - \theta_n^{(2)} \|^2] = E^{1/2}[\| \Gamma_{1:n} \theta_0^{(1)} - \theta_0^{(2)} \|^2] \\
\leq D_2(1 - a\alpha/2)^{n/2} W_2(\lambda_1, \lambda_2) ,
\]
where we have used Corollary 1 for the last inequality. By [37, Theorem 6.16], the space \( \mathbb{P}_2(\mathbb{R}^d) \) endowed with \( W_2 \) is a Polish space. Then, \( (\lambda_1 R_0^n)_{n \geq 0} \) is a Cauchy sequence and converges to a limit \( \pi_{\lambda_1} \in \mathbb{P}_2(\mathbb{R}^d) \), \( \lim_{n \to +\infty} W_2(\lambda_1 R_0^n, \pi_{\lambda_1}) = 0 \). We show that the limit \( \pi_{\lambda_1} \) does not depend
on \(\lambda_1\). Assume that there exists \(\pi_{12}\) such that \(\lim_{k \to +\infty} W_2(\lambda_2 R_{n_k}, \pi_{12}) = 0\). By the triangle inequality

\[
W_2(\pi_{11}, \pi_{12}) \leq W_2(\pi_{11}, \lambda_1 R_{n_k}) + W_2(\lambda_1 R_{n_k}, \pi_{12}) + W_2(\pi_{12}, \lambda_2 R_{n_k}) .
\]

Thus by (65), taking the limits as \(n \to +\infty\), we get \(W_2(\pi_{11}, \pi_{12}) = 0\) and \(\pi_{11} = \pi_{12}\). The limit is thus the same for all initial distributions and is denoted by \(\pi_0\). Moreover, \(\pi_0\) is invariant for \(R_n\). Indeed for all \(k \in \mathbb{N}\), 

\[
W_2(\pi_0 R_n, \pi_0 R_n) = W_2(\pi_0 R_n, \pi_0 R_n) + W_2(\pi_0 P_{n_k}, \pi_0) .
\]

Using (65) again, we get taking \(n \to +\infty\), 

\[
W_2(\pi_0 R_n, \pi_0) = 0 \text{ and } \pi_0 R_n = \pi_0 .
\]

The fact that \(\pi_0\) is the unique stationary distribution is straightforward by contradiction and use of (65). (34) is a simple consequence of (65) taking \(\lambda_2 = \pi_0\).

It remains to show that \(\theta^{(\alpha)}\) is well-defined and has distribution \(\pi_0\). Since \(\{(\mathbf{A}_k, \mathbf{b}_k) : k \in \mathbb{N}_-\} \) is i.i.d., 

\[
\sum_{n \leq -1} E[\theta_n - \theta_{n+1}]^2 = \sum_{n \leq -1} E[\theta_n b_{n-1}]^2 = \sum_{n \leq -1} E[\Gamma_{n,0}]^2 \sum_{n \leq -1} E[\theta_n b_{n-1}]^2
\]

and therefore \(A1-(i)\) combined with Corollary 1 ensures that this series is finite and therefore \((\theta_n)\) defined in (35) is a Cauchy sequence almost surely and in \(L^2\) which ensures its convergence. Finally, assume now that \(\{(\mathbf{A}_k, \mathbf{b}_k) : k \in \mathbb{N}_-\}\) is independent of \(\{(\mathbf{A}_k, \mathbf{b}_k) : k \in \mathbb{N}_+\}\). To conclude it is then sufficient to note that if \(\theta_0 = \theta^{(\alpha)}\), then \(\theta_1\) has the same distribution as \(\theta^{(\alpha)}\) by definition of the recursion (1).

### E.2 Proof of Proposition 9

Consider a sequence \(\{\alpha_n : n \in \mathbb{N}\}\) converging to 0 such that for any \(n \in \mathbb{N}\) \(\alpha_n \in (0, \alpha_2, \infty)\), and let \(u \in \mathbb{S}^{d-1}\). For ease of notation, we simply denote \(G^{(\alpha)}_{k,0} = G^{(\alpha, \alpha)}_{k,0}\). Note that

\[
\alpha_n^{-1/2} u^\top J^{(\alpha, \alpha)}_{\alpha_n} u = \sum_{k = -\infty}^1 \Delta M_{n,k} , \quad \Delta M_{n,k} = \alpha_n^{1/2} u^\top G^{(\alpha)}_{k,0} \varepsilon_{k-1} .
\]

By [15, Theorem 3.6], it is sufficient to show that

\[
\begin{align*}
\sup_{k \leq 1} \Delta M_{n,k} & \xrightarrow{p} 0 , \\
\sum_{k \leq 1} \Delta M_{n,k}^2 & \xrightarrow{p} u^\top \Sigma u , \\
\sup_{w \in \mathbb{N}} \mathbb{E}[\sup_{k \geq 1} \Delta M_{n,k}^2] & < +\infty .
\end{align*}
\]

First, by Markov inequality and Proposition 1 and A1-(i), we have for any \(\eta > 0\) that

\[
\mathbb{P}(\sup_{k \leq 1} \Delta M_{n,k} \geq \eta) \leq \eta^{-4} \mathbb{E}[\sup_{k \leq 1} \Delta M_{n,k}^4] \leq \eta^{-4} \alpha_n^2 \sum_{k \leq 1} \mathbb{E}[\|G_{k,0}^{(n)}\|_4^4 \|\varepsilon_{k-1}\|_4^4] \\
\leq \eta^{-4} \alpha_n^2 \mathbb{E}[\|\varepsilon_0\|_4^4] \sum_{k \leq 1} (1 - a \alpha_n)^{-2(k-1)} \leq \eta^{-4} \alpha_n^2 \mathbb{E}[\|\varepsilon_0\|_4^4] \mathbb{K}_Q^2 (1 - (1 - a \alpha_n)^2)^{-1} ,
\]

which shows that (66) holds.

Denote by \(\Sigma_n\) the unique solution of the Riccati equation (25) with \(\alpha \leftarrow \alpha_n\). We get by Lemma 2 that there exists \(C \geq 0\) such that for any \(n \in \mathbb{N}\),

\[
\|\Sigma - \Sigma_n\| \leq C \alpha_n .
\]

Therefore, we obtain that

\[
|\sum_{k \leq 1} \Delta M_{n,k}^2 - u^\top \Sigma u| \leq \alpha_n |\sum_{k \leq 1} (G_{k,0}^{(n)} u)^\top [\varepsilon_{k-1} \Sigma_{k-1} - \Sigma_x] (G_{k,0}^{(n)} u) + C \alpha_n .
\]

Then, to establish (67), it remains to show that

\[
\alpha_n |\sum_{k \leq 1} (G_{k,0}^{(n)} u)^\top [\varepsilon_{k-1} \Sigma_{k-1} - \Sigma_x] (G_{k,0}^{(n)} u) \xrightarrow{p} 0 \quad \text{as} \quad n \to +\infty .
\]

(69)
This follows from A1-(ii)-(i) and Proposition 1 which shows that

\[
\mathbb{E}[|| \sum_{k \leq 1} ((G_{k,0}^{(n)})^T u)^T [e_{k-1}e_{k-1}^T - \Sigma_e] (G_{k,0}^{(n)})^T u ||^2 ] \\
= \sum_{k \leq 1} \mathbb{E} \left[ ((G_{k,0}^{(n)})^T u)^T [e_{k-1}e_{k-1}^T - \Sigma_e] (G_{k,0}^{(n)})^T u ||^2 \right] \\
\leq \sum_{k \leq 1} ||G_{k,0}^{(n)}||^4 \mathbb{E} [||e_{k-1}e_{k-1}^T - \Sigma_e||^2] \leq \mathbb{E} [||e_0e_0^T - \Sigma_e||^2] \kappa_Q^2 (1 - (1 - a \alpha_n)^2)^{-1}.
\]

Therefore,

\[
\lim_{n \to +\infty} \alpha_n^2 \mathbb{E}[\sum_{k \leq 1} ((G_{k,0}^{(n)})^T u)^T [e_{k-1}e_{k-1}^T - \Sigma_e] (G_{k,0}^{(n)})^T u ||^2 ] = 0,
\]

which completes the proof of (69).

Finally, we show (68) which follows from A1-(ii)-(i) and Proposition 1,

\[
\mathbb{E}[\sup_{k \leq 1} \Delta M_{n,k}^2] \leq \sum_{k \leq 1} \mathbb{E}[\Delta M_{n,k}^2] = \alpha_n \sum_{k \leq 1} ((G_{k,0}^{(n)})^T u)^T \mathbb{E}[e_{k-1}e_{k-1}^T] (G_{k,0}^{(n)})^T u \\
\leq \alpha_n \mathbb{E}[e_0e_0^T] \sum_{k \leq 1} ||G_{k,0}^{(n)}||^2 \leq \mathbb{E}[e_0e_0^T] \kappa_Q / \alpha.
\]
