Abstract

**Background:** *Rubus coreanus* fruit (RF) has been used as a traditional medicine formulation to treat various diseases including diarrhea, asthma, and cancer in East Asia (Korea, China, and Japan). RF, which is native to Korea, has a larger fruit size than that of exotic species. In this study, we aimed to compare the anti-inflammatory activities of immature and mature RF extracted with different solvents.

**Methods:** Mature and immature RF (MRF and IRF) were extracted with 30% ethanol, 70% ethanol and water at room temperature. The antioxidant activity was determined using 2,2-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid (ABTS) assays. Anti-inflammatory activity was determined by measuring nitric oxide (NO) production, expression of inflammatory proteins (inducible NO synthase [iNOS], cyclooxygenase [COX]-2, nuclear factor (NF)-κB, and inhibitor of NF-κB [IκB]), and inflammatory cytokines using polymerase chain reaction in lipopolysaccharide (LPS)-stimulated RAW264.7 macrophages.

**Results:** The IRF 30% ethanol extract showed higher radical scavenging activity in DPPH and ABTS assays (half-maximal inhibitory concentration [IC₅₀] 16.0 ± 0.5 and 15.9 ± 0.4) than MRF did. In addition, the IRF 30% ethanol extract (200 μg/mL) significantly reduced the production of the inflammatory mediator NO by approximately 80% and inhibited iNOS, COX-2, phosphorylated (p)-IκB, and p-NF-κB activation compared with MRF. Moreover, IRF extract decreased the inflammatory cytokines tumor necrosis factor-α, interleukin (IL)-1β, and IL-6 compared with the MRF extract.

**Conclusions:** This study revealed that IRF showed more beneficial effects than MRF did in LPS-stimulated RAW 264.7 macrophages, suggesting that IRF may be a useful anti-inflammatory agent.

**Keywords:** Anti-inflammation, Free radical scavenging, Inflammatory cytokines, NF-κB signaling, *Rubus coreanus* fruit

Background

*Rubus coreanus* fruit (RF), also called the Korean black raspberry, belongs to the family *Rosaceae* and is cultivated in the southern part of Korea, China, and Japan [1]. Immature RF (IRF) has been used to treat diabetes mellitus [2], while mature RF (MRF) has been used in anticancer, anti-inflammatory, and anti-fatigue treatments [3–5].

These potential health benefits of RF are attributed to different components including cyanidin 3-O-glucoside, cyanidin 3-O-xylosylrutinoside, cyanidin 3-O-rutinoside, ellagic acid (EA), and phenolics, such as gallic, protocatechuic, p-hydroxybenzoic, vanillic, syringic, salicylic, and caffeic acids. [6–8]. The levels of linoleic acid, citric acid, succinic acid, and sucrose decreased, while those of glucose and fructose increased during the maturation process [9].

Inflammatory response plays important roles in normal and pathological healing. Following an injury, various factors activate the immune system, leading to a local
inflammatory response [10]. Pro-inflammatory cytokines, such as interleukin (IL)-6, IL-1β, and tumor necrosis factor (TNF), are stimulated and oxygen-centered free radical production is induced. The nuclear factor (NF)-κB transcription factor induces the transcription of pro-inflammatory genes and contributes to inflammation. Activated NF-κB is a stable trimeric complex of two NF-κB subunits (p65 and p50) and inhibitor of NF-κBα (IκBα). NF-κB induces key products such as pro-inflammatory cytokines, cyclooxygenase-2 (Cox-2), and inducible nitric oxide (NO) synthase (iNOS) [11]. Phosphorylation and degradation of IκB allows NF-κB to translocate to the nucleus [12, 13]. NOS isoenzymes [endothelial NOS (eNOS), neuronal NOS (nNOS), and iNOS] synthesize NO, and the production of high NO levels is characteristic of many inflammatory conditions [14]. Therefore, it is necessary to investigate the NOs and NF-κB-induced transcription factors that induce pro-inflammatory cytokines, which subsequently cause inflammation-related diseases [15].

The anti-inflammatory effects of MRF have been previously published [16]; however, there are no reports on the effects of different harvest times and extraction solvents on the anti-inflammatory activity of RF. In this study, we investigated the effects of harvest time and various extraction solvents on the anti-inflammatory effects of RF as well as the potential involvement of NF-κB signaling in the mechanism of action of RF.

### Results

#### Extraction yields of IRF and MRF according to extraction solvent

The yields of IRF extracts with 0, 30, and 70% ethanol were 15.22 ± 0.48, 17.33 ± 0.25, and 14.23 ± 0.19%, respectively, and the corresponding values of MRF extracts were 9.26 ± 0.66, 8.66 ± 0.25, and 8.07 ± 0.00%, respectively. IRF extract yield was higher than that of MRF, and the yield of IRF 30% ethanol extract was the highest.

#### Antioxidant assay of IRF and MRF

The results of antioxidant assays are presented in Table 1. The results of DPPH and ABTS radical scavenging assays were expressed as IC50 values. IRF showed the highest DPPH radical scavenging activity (IC50 of 30% ethanol extract: 16.0 ± 0.5 μg/mL), while MRF showed the lowest (IC50 of 0% ethanol extract: 208.2 ± 17.1 μg/mL). Similar to DPPH results, IRF showed the highest ABTS radical scavenging activity (IC50 of 30% ethanol extract: 15.9 ± 0.4 μg/mL) and MRF showed the lowest (IC50 of 70% ethanol extract: 97.5 ± 2.7 μg/mL). The IRF extract showed significantly low IC50 values in DPPH and ABTS radical scavenging assays (p < 0.05), indicating that IRF exhibited the best antioxidant activity.

#### Table 1 IC50 value of antioxidant activity from 0, 30 and 70% ethanol extracts of mature and immature fruit of Rubus coreanus (n = 3)

| Sample     | DPPH (μg/mL) | ABTS (μg/mL) |
|------------|--------------|--------------|
| MRF 0%     | 208.2 ± 17.1a | 96.6 ± 8.3a  |
| 30%        | 78.7 ± 2.9f  | 67.0 ± 1.6b  |
| 70%        | 178.8 ± 2.0b | 97.5 ± 2.7a  |
| IRF 0%     | 24.0 ± 1.0f  | 21.6 ± 1.1c  |
| 30%        | 16.0 ± 0.5f  | 15.9 ± 0.4d  |
| 70%        | 32.2 ± 1.1d  | 27.6 ± 1.6c  |
| Ascorbic acid | 10.2 ± 0.3e | 34.1 ± 0.3e  |

All values are means ± SD. Means with different letters are significantly different at p < 0.05 by Tukey’s multiple comparison tests. MRF mature Rubus coreanus fruit, IRF immature Rubus coreanus fruit

#### IRF and MRF extracts inhibited NO production in LPS-stimulated RAW264.7 cells

Cell viability was determined after treatment with various concentrations of IRF and MRF extracts (0 to 400 μg/mL). The cell viability values were >90% after exposure to up to 200 μg/mL of the extracts compared with the control (LPS treatment only, Fig. 1); however, the extracts affected cell viability at 400 μg/mL. All extract concentrations < 200 μg/mL were nontoxic to the cells and were therefore used in the subsequent assays. As shown in Fig. 2, NO production in LPS-stimulated RAW264.7 cells significantly decreased. We observed that different concentrations of IRF and MRF inhibited NO production in LPS-stimulated RAW264.7 cells. Specifically, IRF and MRF 30% ethanol extracts (200 and 50 μg/mL, respectively) reduced cell viability. Thus, the extracts were used at a concentration of 200 μg/mL in the next assay.

#### IRF inhibits IL-6, IL-1β, and TNF-α levels in LPS-stimulated RAW264.7 cells

We investigated the effect of IRF and MRF extracts on the expression levels of pro-inflammatory cytokines such as IL-6, IL-1β, and TNF-α. As shown in Fig. 3, RAW264.7 cells treated with LPS alone showed increased expression levels of IL-6, IL-1β, and TNF-α compared with the untreated cells. The expression levels of IL-6, IL-1β, and TNF-α were reduced in LPS-stimulated RAW264.7 cells following treatment with MRF extracts. IRF treatment also attenuated LPS-mediated overproduction of IL-6, IL-1β, and TNF-α. These data indicated that the inhibition of IL-6, IL-1β, and TNF-α by IRF may have been mediated by decreased NO production. The 30% ethanol extract of IRF showed a higher reduction in IL-6 and TNF-α levels.
IRF extract inhibits expression of inflammatory-related proteins in LPS-stimulated RAW264.7 cells

The NF-κB signaling pathway has been reported to be associated with the induction of gene expression of inflammatory mediators such as NO, iNOS, COX-2, IL-6, and TNF-α [11]. NF-κB activation is induced by the degradation of IκBα by IκB kinase-mediated phosphorylation and subsequent p65 nuclear translocation [17]. To determine whether the effects of 0%, 30%, and 70% ethanol extracts of IRF and MRF were mediated by the inflammatory-related proteins p-NF-κB (p65), p-IκB, COX-2, and iNOS in LPS-stimulated RAW264.7 cells, their protein expression was measured by western blotting (Fig. 4 and Additional file 1: Figure S1). LPS significantly enhanced p-p65, p-IκB, COX-2, and iNOS expression in RAW264.7 cells. In addition, RAW264.7 cells treated with LPS and IRF showed a higher reduction in expression of p-p65, p-IκB, COX-2, and iNOS.
than MRF-treated cells did. Furthermore, we showed that treatment of IRF 0 and 30% ethanol extract with LPS strongly suppressed inflammatory-related proteins. Our results suggest that IRF could negatively regulate inflammatory-related proteins in LPS-stimulated RAW264.7 cells and may therefore have anti-inflammatory effects on LPS-treated cells.

**Analysis of EA in IRF and MRF using HPLC**

EA is the main phenolic compound in RF [18, 19] and has beneficial effects, such as anti-inflammation, in mice and in damaged skin [20, 21]. Thus, we performed HPLC analysis to determine whether the inflammation inhibitory effect of IRF is attributed to EA content. The chromatograms of standard solution, MRF extract, and IRF extract are shown.
in Fig. 5. The EA contents of IRF and MRF were 0.75 and 0.10 mg/g dried weight, respectively.

**Discussion**

RF is well known to have various pharmacological effects, including anticancer and anti-inflammatory [2–5, 16] activities, which are attributed to the phenolic compound anthocyanin and EA content [6, 9, 18]. However, the effect of different harvest times and extraction solvents on the anti-inflammatory effects of RF in LPS-stimulated RAW264.7 cells has not yet been examined. This is the first study to compare the anti-inflammatory effects of different solvent extracts of MRF and IRF in LPS-stimulated RAW264.7 cells. Total phenol and flavonoid contents were higher in 75% ethanol extract of MRF than in 25, 50, and 100% ethanol extract of MRF [22]. The anti-oxidant effect of 75% ethanol extracts of MRF and IRF was better than that of 25, 50, and 100% ethanol extracts in liver cells and DPPH radical scavenging activity [22, 23]. In addition, 30% ethanol extract of IRF has beneficial effect osteoporotic by pro-inflammation [24]. Based on these findings, water, 30% ethanol, and 70% ethanol were selected as extraction solvents in this study.

Injuries due to inflammation are mediated by oxygen-derived free radicals and high-energy oxidation, which cause toxic oxidation reactions in the cells [14]. In this study, the IC_{50} values in both ABTS and DPPH free radical scavenging assays were lower for IRF than for MRF. The 30% ethanol extract of IRF showed better antioxidant activity than MRF. RF contains anthocyanins and phenolic compounds in abundance [6], and their composition changes during maturation process. In particular, the contents of organic acids, amino acids, and phenolic compounds are reduced [25], while anthocyanin components formed that are glycosides attach to the phenolics [9]. Phenolic compounds are found in many fruits and vegetables, and they contribute to protective effects against oxidation in organisms [26]. EA is known to be a standard phenolic compound in RF and therefore, EA was selected as a standard component for the analysis. EA exerts potential activities such as anti-inflammatory and anticoagulatory effects in cardiac tissues of diabetic mice and UV–B irradiation-induced inflammation model [20, 21]. In the
present study, IRF contained a higher quantity of EA than MRF did, indicating that the EA component in IRF inhibited the production of pro-inflammatory cytokines and inflammation-related factors in LPS-stimulated RAW264.7 cells. Raw 264.7 macrophages perform major functions such as initiation, maintenance, and resolution of inflammatory process [27]. Our findings showed that IRF efficaciously inhibited p65 NF-κB inflammatory response via cytokine genes in LPS-stimulated RAW264.7 cells. Treatment of RAW264.7 cells with LPS stimulates toll-like receptor 4 and induces the release of pro-inflammatory cytokines necessary to activate immune response [28]. We demonstrated the inhibition of pro-inflammatory factors TNF-α, IL-1β, and IL-6 by IRF. In a previous study, 100% ethanol extract of IRF reduced pro-inflammatory cytokines more effectively than MRF extracts did [16]. However, 0 and 30% ethanol extracts of IRF reduced pro-inflammatory cytokines to a lesser extent than 100% ethanol extract did. Pro-inflammatory cytokine actions involve the activation of NF-κB. Cytokines may be responsible for the induction of COX-2 and iNOS. Furthermore, iNOS produces NO to cause inflammation [14]. In the present study, treatment of LPS-stimulated RAW264.7 cells with 0 and 30% ethanol extracts of IRF reduced NO and inflammatory-related proteins, and these effects were less potent than those induced by the 100% ethanol extract (similar to effects on pro-inflammatory cytokines) [16]. The extract with the highest polyphenol content exhibited the highest antioxidant capacity [6]. A previous study reported that the ethyl acetate fraction of RF, which had the highest polyphenol content, showed the highest NO reduction rate [8]. These results indicate that the ethyl acetate extract of IRF, which had antioxidant ability, showed better anti-inflammatory effects than MRF.

Our results confirmed that the anti-inflammatory effects of 0 and 30% ethanol extracts of IRF, which were mediated by reduction of NF-κB pathway activity via cytokine inhibition in LPS-stimulated RAW264.7 cells, were higher than that of the 70% ethanol extracts of IRF and MRF. This effect may have been mediated by the anti-inflammatory effects of EA in IRF. Therefore, 0 and 30% ethanol extracts of IRF have the potential to be used as therapeutic agents for inflammation-related diseases.

Conclusion
Our results revealed that IRF inhibited inflammatory responses induced by NF-κB signaling and pro-inflammatory cytokines (TNF-α, IL-1β, and IL-6). In addition, the EA content of RF, which is known to have anti-inflammatory activity, was higher in IRF than in MRF. This study was the first to describe the detailed inflammatory mechanisms of IRF and MRF extracted using different ethanol concentrations. Furthermore, these results suggest that IRF could be used as a dietary supplement with potential benefits in treating inflammation-related diseases.

Materials and methods
Preparation of materials, extracts, and yields
R. coreanus grown for 30 and 45–70 days post-bloom (IRF and MRF, respectively) were collected from Gwang Yang in South Korea in 2017. The code and production income sales report number of the plant material (09-01-0026 and 09–004–2005-1) was deposited at the National Forest Seed and Variety Center and identified by PhD. Seok Cheol Suh (Gwangyang Agricultural Technology Center) [29]. In addition, the voucher specimen (NIBRV0000180126) was deposited at National institute of biological resources [30]. Crushed RF samples were stored at −20 °C before extraction and were hot-air dried, crushed, and subsequently extracted. IRF and MRF were reflux extracted three times with different concentrations of ethanol (0, 30, and 70%). The sample extracts were filtered, vacuum evaporated, freeze-dried, stored at −70 °C, and then used in each experiment. The weight of dried samples (W_sample) and freeze-dried extracts (W_extracts) were measured and the yield was calculated using the following equation:

\[
\text{Yield} \% = \frac{W_{\text{extracts}}}{W_{\text{sample}}} \times 100
\]

2,2-Diphenyl-1-picrylhydrazyl scavenging assay
2,2-Diphenyl-1-picrylhydrazyl (DPPH) scavenging assay was carried out using the Müller method [31] with modifications. Sample stock solutions (10 mg/mL) were diluted to final concentrations of 10 to 500 μg/mL in ethanol and mixed with 0.25 mM DPPH solution. After 30 min, the absorbance at 515 nm, which is the maximum absorbance of DPPH, was recorded as Abs_sample. The absorbance was recorded as Abs_blank. The radical scavenging activity (RSA) of each solution was then calculated as a percentage according to the following equation:

\[
\text{RSA} \% = \frac{(\text{Abs}_{\text{sample}} - \text{Abs}_{\text{blank}})}{\text{Abs}_{\text{blank}}} \times 100
\]

The positive control was ascorbic acid, and each value was expressed as the half-maximal inhibitory concentration (IC_{50}), which is the concentration that scavenges 50% of the free radicals.

2,2′-Azino-bis(3-ethylbenzothiazoline-6-sulphonic acid scavenging assay
The 2,2′-Azino-bis(3-ethylbenzothiazoline-6-sulphonic acid (ABTS) scavenging activity of the extracts was
examined against ABTS radical cation generated using chemical method [32]. Sample stock solutions (10 mg/mL) were diluted to final concentrations of 50 to 300 μg/mL in water. ABTS was dissolved in water to a concentration of 7 mM. The radical cations were produced by reacting the stock solution with 2.45 mM of potassium peroxodisulfate and allowing the mixture to stand at –4 °C for 4 h before using the ABTS+ solution. The absorbance at 734 nm of the mixture of ABTS+ and various concentrations of the extracts, recorded as Abs-sample, was measured using a UV/VIS spectrophotometer. A blank experiment was also carried out by the same procedure using water plus the extract solution, and the absorbance was recorded as Abs-blank. The RSA of each sample was calculated as a percentage according to the following equation:

\[
\text{RSA} (\%) = \left(\frac{\text{Abs}_{\text{blank}} - \text{Abs}_{\text{sample}}}{\text{Abs}_{\text{blank}}}\right) \times 100.
\]

The positive control was ascorbic acid and each value was expressed as the IC_{50}.

**Cell culture**

RAW264.7 macrophages were cultured in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with 5% fetal bovine serum (FBS), 1% penicillin-streptomycin (Gibco BRL, Burlington, ON, Canada) at 37 °C in a 5% CO₂ incubator. The medium was replaced every 2 days for subculture.

**Measurement of cell viability**

To evaluate the effects of the extracts on cell viability, a CellTiter 96® AQuous One Solution cell proliferation assay (3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium [MTS]) was performed. The cells were plated in 96-well plates at a density of 1.0 × 10^5 cells/well. After 24 h, the medium was replaced with serum-free medium, and the cells were treated with various concentrations (0 to 400 μg/mL) of IRF and MRF extracts for 1 h, followed by 1 μg/mL of LPS. After 18 h, equal amounts of the culture medium and Griess reagent were reacted in a 96-well plate for 10 min, and the absorbance was measured at 540 nm using a multi-plate reader.

**mRNA analysis using reverse transcription polymerase chain reaction**

RNA from RAW264.7 macrophages was isolated using 1 mL of TRIzol (Ambion, MA, USA). cDNA was synthesized from 1 μg of total RNA using Reverse Transcriptase Premix (Intron, Seongnam-Si, Korea). Polymerase chain reaction (PCR) analysis was performed with 20 ng of cDNA using the Maxime PCR PreMix kit (i-Taq, Intron) to detect TNF-α, IL-6, IL-1β, and glyceraldehyde 3-phosphate dehydrogenase (GAPDH). The forward and reverse primers are presented in Table 2. Reactions were performed on a PCR System, and the thermal profile settings were 50 °C for 2 min and 95 °C for 2 min. In addition, 30 cycles were performed for TNF-α, IL-6, IL-1β, and GAPDH (at 94 °C for 30 s, 58 °C for 30 s, and 72 °C for 30 s). After PCR, electrophoresis was performed using a 1% agarose gel, visualized using loading STAR (Dyne bio) staining, and detected using a UV spectrometer (Davinch-K, Korea).

**Western blotting**

RAW264.7 macrophages were collected and lysed in ice-cold radioimmunoprecipitation assay buffer (Cell signaling, MA, USA) for 30 min. The protein contents were measured by Bradford protein assay (Bio-Rad, CA, USA). Total proteins (20 μg) were subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis and electro-transferred onto polyvinylidene difluoride membrane (Millipore, Darmstadt, Germany). The membranes were blocked with 5% nonfat-milk for 30 min at room temperature and incubated in a 1:1000 dilution of the primary antibody overnight at 4 °C. The primary antibodies used were phospho Nf-κB p-65 (p-p65), for 24 h. The medium was replaced with serum-free medium, and the cells were treated with various concentrations (0 to 400 μg/mL) of MRF and IRF extracts for 1 h, followed by 1 μg/mL of LPS. After 18 h, equal amounts of the culture medium and Griess reagent were reacted in a 96-well plate for 10 min, and the absorbance was measured at 540 nm using a multi-plate reader.

**Table 2** mRNA of forward and reverse primers sequence

| Primer Name | Sequence | Size (bp) |
|-------------|----------|-----------|
| TNF-α       | Forward 5’-CACACTCAGATCATCTTCTCAA-3’ | 198       |
|             | Reverse 5’-TTGAAGAGAACCCTGGAGTAG-3’ |           |
| IL-1β       | Forward 5’-GTACTCATCTATGTGCTTG-3’   | 329       |
|             | Reverse 5’-ATTTTGTGCTGTGGTTCCTC-3’  |           |
| IL-6        | Forward 5’-ATTACAATGCTGCTGGAGAG-3’  | 312       |
|             | Reverse 5’-TTTACCTTGTGTTGAGATATG-3’ |           |
| GAPDH       | Forward 5’-AAAAGGTCATCATCTCAGGC-3’  | 432       |
|             | Reverse 5’-CTCTTGATGTCTACATCAGGG-3’ |           |
phospho-IkB-α (p-IkB-α), Cox-2, iNOS, and β-actin. All antibodies were purchased from Cell Signaling (USA). The membranes were washed three times with Tris-buffered saline plus Tween 20 for 10 min each time. After that, the membranes were incubated in a 1:2000 dilution of horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. The protein reactions were detected using enhanced chemiluminescence reagent (Bio-Rad, CA, USA) and chemi-luminator (Davinch-K, Seoul, Korea).

High-performance liquid chromatography analysis of EA

The analysis of EA was performed using a high-performance liquid chromatography (HPLC) system from Waters 2795 series (TX, USA), equipped with a diode array detector from Waters 2495 series (TX, USA). HPLC separation of EA for quantitative analysis was performed using a reverse phase system. The components of the chromatographic profile of IRF and MRF extracts were identified by comparison with retention times (RT) of peaks in the EA standard solution. An INNO C18 (4.6 × 250 mm, 5 μm) column was used with a mobile phase comprising 0.1% phosphoric acid in water (A) and methanol (B) for EA. The elution program was a modification of the method by Chae et al. [18] with a gradient solvent system (B from 30 to 70% for 25 min). UV detection was performed at 370 nm. The injection volume was 10 μL, the flow rate was 1.0 mL/min, and temperature was 35 °C.

Statistical analysis

All experimental results are presented as the means ± standard deviation (SD) of three independent experiments. The statistical significance of differences in this study was calculated using a one-way analysis of variance using Tukey’s test (GraphPad Prism 5.02).
