Generalized entropic criterion for separability

R. Rossignoli\textsuperscript{1}, N. Canosa\textsuperscript{1}
\textsuperscript{1} Departamento de Física, Universidad Nacional de La Plata, C.C.67, La Plata (1900), Argentina

We discuss the entropic criterion for separability of compound quantum systems for general non-additive entropic forms based on arbitrary concave functions \( f \). For any separable state, the generalized entropy of the whole system is shown to be not smaller than that of the subsystems, for \( f \) is concave, providing thus a necessary criterion for separability. Nevertheless, the criterion is not sufficient and examples of entangled states with the same property are provided. This entails, in particular, that the conjecture about the positivity of the conditional Tsallis entropy for all \( q \), a more stringent requirement than the positivity of the conditional von Neumann entropy, is actually a necessary but not sufficient condition for separability in general. The direct relation between the entropic criterion and the largest eigenvalues of the full and reduced density operators of the system is also discussed.

PACS numbers: 03.65.Ud, 03.67.-a, 05.30.-d

The concept of quantum entanglement\textsuperscript{1} has aroused great interest in recent years, due to its deep implications for quantum computation\textsuperscript{2}, quantum cryptography\textsuperscript{3} and quantum teleportation\textsuperscript{4}. The relation between entropy and quantum entanglement has also attracted the attention from several authors\textsuperscript{5–10}. It is well known, for instance, that the von Neumann entropy of a compound quantum system may be larger or smaller than that of a subsystem\textsuperscript{11,12}. However, if the system is in a separable (i.e., unentangled) state, the von-Neumann entropy of the whole system is not smaller than that of a subsystem\textsuperscript{13,14}. Unfortunately, the converse is not true, i.e., the same may occur when the system is in an inseparable (i.e., entangled) state, so that this entropy provides only a necessary test for separability. The von Neumann based criterion is actually rather weak, being a necessary but not sufficient condition for separability. The von Neumann entropy of an inseparable (i.e., entangled) state, so that this entropy could provide a necessary and/or sufficient test in general and whether other information measures providing similar results are given.

Let us consider a quantum system described by a density operator \( \rho \). We will examine the general entropic forms\textsuperscript{15}

\[ S_f(\rho) = Tr f(\rho) = \sum_i f(p_i) , \]

where \( f \) is a smooth concave function \( f'(p) \) decreasing for \( p \in (0,1) \) satisfying \( f(0) = f(1) = 0 \), and \( p_i \), \( i = 1, \ldots, n \), are the eigenvalues of \( \rho \). We assume a finite dimension \( n \). The von Neumann entropy is recovered for

\[ f(p) = -kp\ln p , \]

with \( k > 0 \), while the Tsallis entropy corresponds to\textsuperscript{20}

\[ f(p) = (p-p^q)/(q-1), \quad q > 0 \]

which approaches \( -p\ln p \) for \( q \to 1 \). The generalized entropies\textsuperscript{11} satisfy most basic properties of the conventional entropy, except those related with additivity. In particular, \( S_f(\rho) \geq 0 \), with \( S_f(\rho) = 0 \) iff the system is in a pure state \( \rho^2 = \rho \), while its maximum is attained for the fully mixed state \( \rho = 1/n \textsuperscript{21} \). Concavity of \( f \) ensures concavity of \( S_f(\rho) \textsuperscript{17} \) \( (S_f(\sum_i q_i \rho_i) \geq \sum_i q_i S_f(\rho_i)) \) for \( 0 \leq q_i \leq 1, \sum_i q_i = 1 \). It can be shown\textsuperscript{13,21} that if \( |pf''(p)|' \leq 0 \ (\geq 0) \), then \( S_f \) is sub(super)-additive, i.e.,\textsuperscript{14}

\[ S_f(\rho_A \otimes \rho_B) \leq S_f(\rho_A) + S_f(\rho_B) \leq 0 \ (\geq 0) \]  

The condition \( |pf''(p)|' = 0 \) determines in fact Eq. \textsuperscript{2}. The Tsallis entropy is, accordingly, sub(super)-additive for \( q > 1 \) (\( q < 1 \)).

A fundamental property of the forms\textsuperscript{11} which will be employed in this work, and which justifies their use as...
information measures, is that if $\rho$ is more mixed than a density operator $\rho'$, then

$$S_f(\rho) \geq S_f(\rho'),$$

(4)

for any $f$ of the previous form $^{17}$. Labeling the eigenvalues of $\rho$ and $\rho'$ in decreasing order, i.e. $p_1 \geq p_2 \geq \ldots \geq p_n, \rho$ is said to be more mixed (or disordered) than $\rho'$ if

$$S_i = \sum_{j=1}^{i} p_j \leq S'_i = \sum_{j=1}^{i} p'_j, \quad i = 1, \ldots, n - 1,$$  

(5)
i.e., if $p_1 \leq p'_1, p_1 + p_2 \leq p'_1 + p'_2,$ etc. (for $i = n$, $S_n = S'_n = 1$). Mathematically, this states that the set of probabilities $(p_1, \ldots, p_n)$ is majorized by $(p'_1, \ldots, p'_n)$. Eq. (4) can be immediately derived writing $p_i = S_i - S_{i-1}$ in (1), with $S_0 = 0$. $S_f(\rho)$ is then a decreasing function of $S_i$ for $1 \leq i \leq n - 1$, as $\partial S_f/\partial S_i = f'(p_i) - f'(p_{i+1}) \leq 0$ if $p_i \geq p_{i+1}$ and $f$ is concave (Eq. (4)) follows then from the mean value theorem; note that the allowed values of $S_i$ form a convex set defined by $S_i \leq S_{i+1}, S_i \geq (S_i - S_{i+1})/2, \text{with } S_0 = 0, S_n = 1$.

Moreover, it can be shown $^{17}$ that $\rho$ is more mixed than $\rho'$ if and only if $\text{Tr} f(\rho) \geq \text{Tr} f(\rho')$ for any concave function $f$, i.e., if $\text{Eq. (4)}$ holds $\forall$ $f$ of the previous form (the conditions $f(0) = f(1) = 0$ fix just an arbitrary linear term $ap + b$ that can be added to $f$ without affecting concavity or Eq. (4)). If the dimensions of $\rho$ and $\rho'$ differ, we may apply the same definition of more mixed by adding zero eigenvalues to the density with the smallest dimension, which leaves $S_f$ unchanged.

Let us consider now a system composed of two subsystems $A$ and $B$. The quantity

$$S^A_f(\rho) = S_f(\rho) - S_f(\rho_A) = \text{Tr} f(\rho) - \text{Tr}_A f(\rho_A),$$

(6)

where $\rho_A = \text{Tr}_B \rho$ is the reduced density matrix of system $A$ and $\text{Tr} = \text{Tr}_A \text{Tr}_B$, plays the role of a conditional entropy. In the von Neumann case, Eq. (6) becomes the usual conditional entropy $^{17}$.

$$S^A_f(\rho) = S(B|A) = -\text{Tr}_B \rho [\ln \rho - \ln \rho_A \otimes I_B],$$

whereas in the Tsallis case, it is proportional to the $q$-conditional entropy defined in $^{11,12}$, $S_q(B|A) = S^A_f(\rho)/\text{Tr} \rho^A_q$.

For a discrete classical system described by a joint probability distribution $p_{ij}$, Eq. (6) is always non-negative, i.e.,

$$\sum_{i,j} f(p_{ij}) - \sum_i f(p_i) \geq 0, \quad p_i = \sum_j p_{ij},$$

(7)
since for any concave $f$ satisfying $f(0) = 0$, we have $f(p + q) \leq f(p) + f(q)$ if $p \geq 0, q \geq 0$ (it may be also seen that the set of probabilities $\{p_i\}$ is any more mixed than $\{p_i\}$). This implies that $S^A_f(\rho) \geq 0$ for any uncorrelated density $\rho = \rho_A \otimes \rho_B$ (i.e. $p_{ij} = p^A_i p^B_j$) as well as for any density diagonal in a basis of product states ($\rho = \sum_{i,j} p_{ij} |i\rangle \langle i| \otimes |j\rangle \langle j|$). Nevertheless, in the general quantum case, $S^A_f(\rho)$ may of course be negative. In particular, for a pure state $\rho = |\Psi\rangle \langle \Psi|, S_f(\rho) = 0$ and the positive eigenvalues of $\rho_A$ and $\rho_B$ are identical $^{17}$, whence

$$S^A_f(\rho) = -S_f(\rho_A) = -S_f(\rho_B) \leq 0.$$  

(8)

For $f(p) = -p \log_2 p$, this is just the usual definition of the entanglement of a pure state $|\Psi\rangle$ $^{22,23}$.

Negative values of $S^A_f(\rho)$ are then indicative of distinctive quantum correlations. In particular, for the case $^{4}$ it has been conjectured $^{11,12}$ that the sign of the difference (9) may provide a criterion for determining the separability of $\rho$ $^{13}$. Let us recall that a mixed state $\rho$ is separable (or classically correlated) iff it can be written as a convex combination of uncorrelated densities $^{24}$,

$$\rho = \sum_{\alpha} \omega_{\alpha} \rho^A_\alpha \otimes \rho^B_\alpha, \quad 0 \leq \omega_{\alpha} \leq 1,$$  

(9)

with $\sum_{\alpha} \omega_{\alpha} = 1$. Otherwise it is called entangled or inseparable. For the Tsallis case, it has been shown $^{11,12}$ that the criterion $S^A_f(\rho) \geq 0$ leads, for $q \to -\infty$, to the necessary and sufficient condition for separability for some important classes of states, like Werner states. Nevertheless, we will show here that this does not hold in general. In particular, for an entangled state $S^A_f(\rho)$ may in fact be both positive for any concave $f$ (including the $q \to \infty$ limit in the Tsallis case), indicating that entanglement cannot be always detected by such entropic criteria (or, in general, by information based on the eigenvalues of $\rho$ and $\rho_A, B$ alone). This may occur already for a two qubit system, where the Peres necessary criterion for separability $^{18}$ is known to be sufficient $^{14}$, so that the entropic criterion is here weaker than the Peres criterion.

Let us first show that Eq. (6) is indeed positive for any separable $\rho$. A fundamental theorem demonstrated in $^{25}$ states that if $\rho$ is separable, then $\rho$ is more mixed than $\rho_A$ and $\rho_B$ (disorder criterion for separability). Hence, Eq. (4) implies that if $\rho$ is separable, then

$$S^A_f(\rho) \geq 0,$$  

(10)

and similarly, $S^B_f(\rho) \geq 0$, for any concave $f$ (satisfying $f(0) = 0$). This is in fact an equivalent entropic formulation of the disorder criterion. For a separable state, Eq. (10) will therefore hold $\forall q > 0$ in the case $^{4}$, implying $\text{Tr} \rho^q - \text{Tr}_A \rho^q_A \leq 0 (\geq 0)$ if $q > 1 (0 < q < 1)$. Note that this entails $S^q_A(\rho) \geq S^q_A(\rho_A) \forall \alpha > 0$, where $S^q_A(\rho) = \frac{1}{1-\alpha} \ln \text{Tr} \rho^\alpha$ is the Rényi entropy $^{2,26}$ (which is additive but not of the form (1), and approaches the von Neumann entropy for $\alpha \to 1$). The disorder criterion is, however, not sufficient $^{25}$, so that Eq. (10) provides in general only a necessary test for separability, as will be explicitly seen below.

For a system of two qubits, Eq. (10) is actually an immediate consequence of the more obvious fact that for
any separable state,

\[ p_1 \leq p_1^A , \]  

(11)

where \( p_1 (p_1^A) \) denotes the largest eigenvalue of \( \rho (\rho_A) \). This is so because the difference

\[ \rho_d = \rho_A \otimes I_B - \rho = \sum_{\alpha} \omega_{\alpha} \rho_A^\alpha \otimes (I_B - \rho_B^\alpha) , \]  

(12)

is a non-negative operator if all \( \omega_{\alpha} \geq 0 \) \[27\]. Hence, denoting with \( |i\rangle \) any eigenstate of \( \rho \), we have

\[ 0 \leq \langle i| \rho_d |i\rangle = \langle i| \rho_A \otimes I_B |i\rangle - p_i \leq p_1^A - p_i , \]  

(13)

since \( \langle i| \rho_A \otimes I_B |i\rangle \leq \langle 1_A 1_J B | \rho_A \otimes I_B |1_A 1_J B \rangle = p_1^A \), where \( \rho_A |1_A \rangle = |p_A \rangle |1_A \rangle \) and \( |j_B \rangle \) is any state of \( B \). For a two qubit system, (11) already implies that \( \rho \) is more mixed than \( \rho_A \): \( \sum_{i=1}^\infty p_i \leq p_1^A + p_2^A = 1 \) for \( i = 2, 3, 4 \).

There are two important remarks to make here. First, if \( p_1 > p_1^A \), the state is certainly entangled, but \( \rho_A \) is not necessarily more mixed than \( \rho \), entailing that \( S_f^A (\rho) \) is not necessarily negative for any \( f \). Nevertheless, in the Tsallis case, as well as for any set of entropic functions

\[ f(p) = k[p - g_q(p)] , \]  

(14)

where \( k > 0 \) and \( g_q(p) \) is a convex increasing function satisfying \( g_q(0) = 0, g_q(1) = 1 \) and

\[ \lim_{q \to \infty} g_q(p')/g_q(p) = 0 \text{ if } p' < p , \]  

(15)

\( S_f(\rho) \) will be a decreasing function of the largest eigenvalue \( p_1 \) for sufficiently large \( q \) and finite dimension \( (S_f(\rho) \approx k(1 - d_1 g_q(p_1)) \) in this limit, with \( d_1 \) the multiplicity of \( p_1 \). Hence, if \( p_1 > p_1^A , S_f^A (\rho) \) will become negative for sufficiently large \( q \), and the entropic criterion will be able to detect entanglement. In other words, for \( q \to \infty, S_f^A (\rho) < 0 \) iff \( p_1 > p_1^A \), which is a sufficient condition for inseparability. Note that Eq. (3) is of the form \( 13 \) for \( q > 1 \) and satisfies \( 15 \). Another example is

\[ f(p) = [p - \frac{e^{qp} - 1}{e^q - 1}] / q , \]  

(16)

which is concave \( \forall q \), approaches \( \frac{1}{2} p(1 - p) \) for \( q \to 0 \) \( (q = 2 \text{ case in } 13) \) and is of the form \( 14 \) for \( q > 0 \).

Nonetheless, and this is the second important remark, there are entangled states for which \( p_1 \leq p_1^A \) and \( p_1^B \), i.e., for which the greatest eigenvalue of \( \rho \) remains smaller than that of \( \rho_A \) and \( \rho_B \). This may occur already for a system of two qubits, in which case \( \rho \) will remain more mixed than \( \rho_A \) and \( \rho_B \), and \( S_f^A (\rho) , S_f^B (\rho) \) will both be non-negative for any concave \( f \). This type of entanglement will therefore not be detected by the previous entropic criterion.

An example is the state considered in \( 18 \),

\[ \rho = x|\Psi_0\rangle \langle \Psi_0| + (1 - x)|\uparrow\uparrow\rangle \langle \uparrow\uparrow| , \quad 0 \leq x \leq 1 , \]  

(17)

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1.png}
\caption{Top: The largest eigenvalue \( p_1 \) of \( \rho \) and \( p_1^A \) of \( \rho_A \), for the density \( 17 \), as a function of the parameter \( x \). The dotted line depicts the lowest eigenvalue \( \sigma_1 \), of the partial transpose of \( \rho \). Center: The normalized entropic difference \( 15 \) for the Tsallis case \( 3 \), at the indicated values of \( q \). The curve for \( q = 1 \) corresponds to the von Neumann entropy, in which case \( S_f^A = S(B|A) \). Bottom: The same quantity for the entropic function \( 16 \). The curve for \( q = 0 \) depicts the limit \( S_f^A = \frac{1}{2} \text{Tr} [\rho_B^2 - \rho^2] \). The point where \( p_1 = p_1^A \) is indicated by \( x_c \). Both \( x \) and the quantities plotted are dimensionless.}
\end{figure}

where \( |\Psi_0\rangle = (|\downarrow\downarrow\rangle - |\uparrow\uparrow\rangle)/\sqrt{2} \) is the singlet (a maximally entangled state) and \( |\uparrow\uparrow\rangle \) a maximally polarized separable state. As shown in \( 18 \), Peres criterion determines that this state is entangled \( \forall x > 0 \): the partial transpose of \( \rho \) (defined as the transposition with respect to the indexes of system \( A \)), which is still a density operator if \( \rho \) is separable, has always a negative eigenvalue for \( x > 0 \), namely \( \sigma_1 = \frac{1}{2} (1 - x - \sqrt{1 - 2x(1-x)}) \) \( (\sigma_1 = -x^2/4 + O(x^3) \text{ for } x \to 0) \).

However, as the eigenvalues of \( \rho \) are \( (x, 1 - x, 0, 0) \), and those of \( \rho_A \) and \( \rho_B \) are \( (1-x/2, x/2) \), the greatest eigenvalue of \( \rho \) \( (p_1 = x \text{ for } x > \frac{1}{2}) \) is greater than that of \( \rho_A \) \( (p_1^A = 1 - x/2) \) only for \( x > x_c = 2/3 \) \( [\text{Fig. 1}] \). Hence, for \( 0 < x < 2/3 \), entanglement will not be detected by \( S_f^A (\rho) \), for any \( f \). This can also be directly seen from the explicit expression

\[ S_f^A (x) = f(x) + f(1-x) - f(x/2) - f(1-x/2) \].
Since for a two state system, the entropy $f(p) + f(1-p)$ is a decreasing function of the largest eigenvalue ($f'(p) - f'(1-p) < 0$ for $p > 1/2$ and $f$ concave), in this case $S^A_f(\rho) < 0$ iff $p_1 > p_1^A$, i.e., $S^A_f(x) < 0$ iff $x > 2/3$, for any $f$. The sign of $S^A_f(x)$ is independent of the choice of entropic function $f$ in this example, i.e. independent of $q$ in the Tsallis case or in Eq. (16), as shown in Fig. 1. For normalization purposes, we have plotted the quantity

$$S^A_f(\rho) = S^A_f(\rho)/\text{Tr} g_\rho(\rho_A),$$

where $g_\rho(p) = p^\rho$ in the Tsallis case (19) (so that $S^A_f(\rho) = S_\rho(B\mid A)$ and $g_\rho(p) = (e^{qp} - 1)/(e^q - 1)$ for Eq. (16).

This situation is actually not very special. Consider for instance the more general state

$$\rho = x|\Psi_0\rangle\langle\Psi_0| + (1-x)|uv\rangle\langle uv|,$$

where $|uv\rangle = |u\rangle_A|v\rangle_B$ is an arbitrary separable pure state of the two qubits. This state is again entangled $\forall x > 0$, since the partial transpose of $\rho$ has a negative eigenvalue

$$\sigma_1 = \frac{1}{2}(1-x) - \sqrt{1-2x(1-x)r}, \quad r = |\langle u|v\rangle|^2,$$

with $\sigma_1 = -x(1-r)/2 + O(x^2)$ for $x \to 0$. On the other hand, the eigenvalues of $\rho$ are

$$\left(\frac{1}{2}(1+z), \frac{1}{2}(1-z), 0, 0\right), \quad z = \sqrt{1-2x(1-x)(1+r)},$$

while those of $\rho_A, \rho_B$ are again $(1-x/2, x/2)$. Hence, $p_1 = (1+z)/2, p_1^A = (1-x/2)$, and $p_1 > p_1^A$ only for

$$x > x_c = 2r/(1+2r).$$

Thus, $S^A_f(\rho) < 0$ iff $x_c < x < 1$, for any concave $f$. Again, the entropic criterion fails to detect entanglement for $0 < x < x_c$. For $r = 1$, we recover the results of the previous example, whereas for $r = 0$, i.e. $|uv\rangle = |\uparrow\downarrow\rangle$, $\sigma_1 = -x/2$ and $x = 0$, so that $S^A_f(\rho) < 0 \forall x > 0$. This is the only case where the entropic criterion predicts the full interval of inseparability.

Let us still consider the example ofrefs. [18, 28],

$$\rho = x|\Psi\rangle\langle\Psi| + (1-x)(|\uparrow\uparrow\rangle\langle\uparrow\uparrow| + |\downarrow\downarrow\rangle\langle\downarrow\downarrow|)/2,$$

with $|\Psi\rangle = a|\uparrow\rangle + b|\downarrow\rangle$, $|a|^2 + |b|^2 = 1$. As shown in [18], this state is entangled just for

$$x > x_c = (1 + 2|ab|)^{-1},$$

since the lowest eigenvalue of the partial transpose is $\sigma_1 = (1-x(1+2|ab|)) / 2$ for $x > 2[1+|ab|(1+2|ab|)]^{-1}$. However, the eigenvalues of $\rho$ are $(x, (1-x)/2, (1-x)/2)$ while those of $\rho_A, \rho_B$ are $(1\pm x(|b|^2-|a|^2))/2$. The largest eigenvalue of $\rho$ ($p_1 = x$ for $x > 1/3$) is greater than that of $\rho_A$ ($p_1^A = (1+x(|a|^2-|b|^2))/2$) only for

$$x > x_c = (2-||a|^2-|b|^2||)^{-1}.$$

But $x_c > x_c$, with $x_c = x_c$ just for $|a| = |b|$ or in the trivial separable case $b = 0$ or $a = 0$. Hence, if $|a| \neq |b|$ and $ab \neq 0$, $S^A_f(\rho)$ will not detect entanglement for $x_c < x < x_c$. Note also that for $x > x_c$, $S^A_f(\rho)$ is in this case not necessarily negative for any $f$, but will become negative for sufficiently large $q$ in the Tsallis case or in Eqs. (14) or (16), as shown in Fig. 2. The value of $x$ where $S^A_f(\rho) = 0$ converges actually exponentially fast to $x_c$ for $q \to \infty$ in (3) or (16). This will occur whenever the degeneracies of $p_1$ and $p_1^A$ coincide.

The entropic criterion will provide, however, necessary and sufficient conditions for separability for any density $\rho$ diagonal in the Bell basis $|\tilde{i}\rangle$, i.e. the basis of maximally entangled states $|\Psi_0\rangle, |\Psi_1\rangle = (|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle)/\sqrt{2}$, $|\Psi_{2,3}\rangle = (|\uparrow\uparrow\rangle \pm |\downarrow\downarrow\rangle)/\sqrt{2}$. In such a case,

$$\rho = \sum_{i=0}^{3} q_i |\Psi_i\rangle\langle\Psi_i|,$$

is known to be entangled iff $p_1 > 1/2$ [4], where $p_1 = \text{Max}\{|q_i|\}$ is the largest eigenvalue of $\rho$. This may be obtained directly with Peres criterion, as the partial transpose of $\rho$ has eigenvalues $\frac{1}{2} - q_i$. Now, for any pure Bell state $|\Psi_i\rangle\langle\Psi_i|$, the reduced density matrices are fully mixed, with eigenvalues $(\frac{1}{2}, \frac{1}{2})$, so that the same will oc-
FIG. 3. Same details as Fig. 1 for the density (22). The values of $q$ for the different lines in the center and bottom panels are the same as those of Fig. 1.

cur for any state of the form (21). The condition $p_1 \leq p_1^A$ then becomes equivalent, for any state (21), to $p_1 \leq 1/2$, i.e., to the necessary and sufficient condition for separability. The entropic criterion will therefore always lead to this condition for $q \to \infty$ in (14).

This explains why the entropic criterion for $q \to \infty$ yields the necessary and sufficient condition for separability for Werner-Popescu states (24) (28),

$$\rho = x|\Psi_0\rangle\langle\Psi_0| + (1 - x)I/4, \quad (22)$$

where $I = \sum_{i=0}^3 |\Psi_i\rangle\langle\Psi_i| = I_A \otimes I_B$ is the identity. The eigenvalues of $\rho$ are $p_1 = (1 + 3x)/4$ and $(1 - x)/4$ (threefold degenerate), and the equation $p_1 \leq 1/3$ yields $x \leq 1$, the necessary and sufficient condition (18) (30). Accordingly, for $x > x_c = \frac{1}{3}$, $S_f^A(\rho)$ will become negative for sufficiently large $q$. The root $x_c$ where $S_f^A(\rho) = 0$ will approach $x_r$ for $q \to \infty$, as seen in Fig. 3 although the convergence is in this case less rapid due to the different degeneracies of $p_1$ and $p_1^A$.

For large $q$,

$$x_r \approx \frac{1}{3} + \frac{2\gamma \ln 2}{3q}, \quad (23)$$

where $\gamma = 1$ for the Tsallis case and $\gamma = 2$ for Eq. (10).

Note that the state (20) also becomes of the form (21) for $a = \pm b$ (where the entropic criterion works), as in this case $|\Psi\rangle = |\Psi_0\rangle$ or $|\Psi_1\rangle$ (the remaining term in (20) is proportional to $\sum_{i=2,3}|\Psi_i\rangle\langle\Psi_i|$).

Similar considerations hold for Werner-like states for $n$ qubits (31),

$$\rho = x|\Psi\rangle\langle\Psi| + (1 - x)I/d^n, \quad (24)$$

where $d = 2$, $|\Psi\rangle = (|\uparrow\uparrow\ldots\uparrow\rangle + |\downarrow\downarrow\ldots\downarrow\rangle)/\sqrt{2}$ is a maximally entangled state (a GHZ state (32) and $I$ the identity. The eigenvalues of (21) are $p_1 = x + (1 - x)/d^n$ and $(1 - x)/d^n$ [(d-d-1)-fold degenerate]. Now, for a subsystem $A_m$ with $m$ qubits ($1 \leq m \leq n - 1$), the reduced density matrix $\rho_m$ can be easily shown to have eigenvalues $p^m_i = x/d + (1 - x)/d^n$ (d-fold degenerate) and $(1 - x)/d^n$ [(d-m-d)-fold degenerate]. The necessary condition for separability between the $m$ and $n - m$ subsystem, $p_1 \leq p^m_1$, leads to

$$x \leq x_{c,m} \equiv [1 + d^{n-m}(d - 1)]^{-1}, \quad (25)$$

which is a decreasing function of $m$. The most stringent condition is then obtained for $m = n - 1$, i.e., $x \leq (1 + d^{n-1})^{-1}$, which, according to refs. (31) (33), is just the necessary and sufficient condition for separability. The entropic criterion $S_f^{d,m}(\rho) \geq 0$ will then lead to Eq. (24) for $q \to \infty$ (as shown in (11) for the Tsallis case). If $d$ is an arbitrary integer (\geq 2), the previous discussion and expressions are actually also valid for $n$ qudits (n d-dimensional systems), when $|\Psi\rangle$ is the fully entangled state $\sum_{k=0}^{d-1} |k\rangle\ldots|k\rangle/\sqrt{d}$ (32).

It should be stressed that for bipartite systems with subsystem dimension $d > 2$, the first violation of the majorization relation between $\rho$ and $\rho_A$ in an entangled state may also occur for $i > 1$ in Eq. (4). For instance, let us briefly discuss the example given in (13), dealing with a system of two identical harmonic oscillators. It was shown that for certain densities, $S_f^A(\rho)$ becomes negative just in a finite interval of $q$ values in the Tsallis case, remaining positive for arbitrary large $q$. This indicates that $\rho$ is not more mixed than $\rho_A$, and hence entangled, but still has $p_1 < p_1^A$, which ensures that $S_f^A(\rho)$ remains positive for $q \to \infty$. The first violation of the inequalities (10) is therefore taking place for $i > 1$ (we have verified that this occurred for $i = 2$). Nevertheless, it should be remarked that in such situations, if $S_i$ is only slightly larger than $S_i^A$ and $i > 1$, $S_i^A(\rho)$ may remain positive for all $q > 0$ in the case (33), being then unable to detect entanglement. The same happens with the entropy (10).

In summary, we have shown that the general entropic criterion $S_f^A(\rho) = S_f(\rho) - S_f(\rho_A) \geq 0$ constitutes, for any concave entropic function $f$, a necessary condition for separability. For $q \to \infty$ in Eq. (3), or in general Eq. (14), it becomes equivalent to the condition (11) between the largest eigenvalues of $\rho$ and $\rho_A$. Nonetheless, the entropic criterion is not a sufficient one in general. We have provided examples of entangled densities of two qubits where $p_1 < p_1^A$, in which case $\rho$ remains more mixed than $\rho_A$, implying $S_f^A(\rho) \geq 0$ for any choice of
entropic function $f$. However, the condition $p_1 \leq p_A^1$ becomes sufficient in some important cases, which include any density diagonal in the Bell basis in a two qubit system, and also Werner-like states in $n$ qubit (or qudit) systems. In these cases the inequality $S_f^A(\rho) \geq 0$ will lead, for $q \to \infty$ in Eq. (3) or (14), to the necessary and sufficient condition for separability.

The condition $S_f^A(\rho) \geq 0$ for any concave entropic function $f$ is equivalent to the requirement that $\rho$ be more mixed than $\rho_A$, a general necessary condition for separability \[25\]. Let us remark that this requirement is stronger than the condition $S_f^A(\rho) \geq 0 \forall q > 0$ in \[4\] (or $\forall q$ in \[16\]). Other families of concave entropic functions are required in general to detect that $\rho$ is not more mixed than $\rho_A$ when the first violation of Eqs. (5) occurs for $i > 1$, although in many cases this can also be seen with the entropies \[4\] or \[16\]. In such situations $S_f^A(\rho)$ will remain positive for $q \to \infty$ but may become negative at finite values of $q$.
