Dear Editors,

We read with great interest the paper written by Bykanov et al. describing the sensitivity of three-dimensional (3D) time-of-flight (TOF) 3.0 T magnetic resonance angiography in visualizing the number and course of lenticulostriate arteries (LSAs) in patients with insular gliomas (Bykanov et al., 2021). We congratulate the authors for their important study. We agree that resection of insular gliomas is still challenging, predominantly due to the risk of iatrogenic injury to LSAs. Their finding, elucidating the informative value of preoperative 3D TOF angiography, may certainly help during surgical strategy planning.

However, we would like to comment on the authors’ discussion concerning the possibility of intraoperative visualization of LSAs using ultrasound. Referring to our previous work (Steno et al., 2016), the authors describe their negative experience which is opposite to our finding that navigated 3D-ultrasound (3DUS) power Doppler mode may enable intraoperative visualization of LSAs. Additionally, Bykanov et al. stated that it is difficult to detect the intraparenchymatous segment of the LSAs 0.5–0.1 mm in diameter in the surgical wound during the final stages of tumor resection.

While we agree with the authors that the intraoperative identification of LSAs using ultrasound is non-trivial, we think that the method we presented is promising, and at least in some cases may help to prevent injury of LSAs during removal of insular gliomas. Of note, another ultrasound-based method of LSAs identification using audio signal of intraoperative micro-Doppler recordings has been reported by Yaşargil et al. (Yaşargil et al., 2002) years before we published the paper describing direct LSAs visualization by navigated 3D-US power Doppler mode.

The quality of LSAs ultrasound imaging is currently being evaluated at our department in a prospective study. Hence, we would like to shortly present our last included patient operated in December 2021. As seen in Fig. 1, LSAs were clearly depicted, and not only before the resection, but also toward its end, when a relatively large resection cavity was present.

We hypothesize several reasons why Bykanov et al. have not been successful in ultrasound visualization of LSAs.

First, the quality of ultrasound scanner is not negligible when delicate structures, such as submillimeter LSAs, should be visualized. The ultrasound system the authors used during their study was introduced almost 15 years ago; more sensitive ultrasound scanners providing higher image quality are currently available. Notably, one of the main reasons why we cancelled our first prospective study on 3D-US power Doppler visualization of LSAs in 2016 was the fact that the navigated 3D-US system we had at that time (SonoWand Invite, SONOWAND AS, Trondheim, Norway) was equipped with an out-of-date ultrasound scanner. A new study on the same topics has been started at our department in 2021, after we obtained a high-end 3D-US system (ultrasound bk5000, BK Medical Aps, Herlev, Denmark integrated with neuronavigation Curve, Brainlab AG, Munich, Germany), better at depicting vascular structures (Steno et al., 2021).

Second, Bykanov et al. most likely did not use 3D-US during their study; to the best of our knowledge, the combination of neuronavigation and ultrasound system used by the authors does not enable 3D rendering of ultrasound images. However, ultrasound imaging in standard axial, coronal and sagittal planes rendered by 3D-US systems makes anatomical identification of various structures much less challenging compared to 2D ultrasound; recognition of LSAs is most probably not an exemption.

Lastly, the authors did not clarify which Doppler mode (color or power Doppler) they have negative experience with (Bykanov et al., 2021; Pitskhelauri and Bykanov, 2021). The methodology we presented is based on power Doppler mode (Steno et al., 2016), which is more sensitive for depicting flow in small vessels than the standard color Doppler (McDicken and Anderson, 2002).

Identification of LSAs using 3D-US power Doppler certainly has some limitations, which we will report after finalizing our ongoing prospective study. Because the reliability of LSAs depiction by 3D-US is yet uncertain, surgeons must still adhere to all standard precautions in order to prevent injury to LSAs. On the other hand, none of these techniques was proven to be fully reliable, especially when insular tumors incorporate LSAs. This is true also for the authors’ previous findings, that the resection of medial tumor portion should stop when beige-colored putamen or lenticulostriate veins (referred also as inferior striate veins, Rhoton, 2002) were detected (Pitskhelauri and Bykanov, 2021). The importance of both aforementioned anatomical landmarks was reported before ( Yaşargil et al., 2002), nevertheless, while undoubtedly helpful, anatomical landmarks are often insufficient for the exact location of the perforating arteries on their whole trajectory (Duffau, 2009).
In conclusion, in our opinion neurosurgeons should be aware that navigated 3D-US power Doppler may enable direct LSAs visualization, which may serve as a warning sign at least in some insular glioma cases.

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Informed consent

Informed consent was obtained from the presented patient.

Availability of data and material (data transparency)

The datasets generated during and/or analyzed during the presented case are available from the corresponding author on reasonable request.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Declaration of competing interest

None.
