Abstract

We construct a wide class of finite \( \mathcal{W} \)-algebras as truncations of Yangians. These truncations correspond to algebra homomorphisms and allow to construct the \( \mathcal{W} \)-algebras as exchange algebras, the R-matrix being the Yangian’s one.

As an application, we classify all irreducible finite dimensional representations of these \( \mathcal{W} \)-algebras and determine their center.

1 Introduction

It has already been proven \[1\] that there exists an algebra homomorphism between Yangian based on \(sl(N)\) and finite \(W(sl(Np), N.sl(p))\)-algebras. Such a connection plays a role in the study of physical models: for instance, in the case of the \(N\)-vectorial non-linear Schrödinger equation on the real line, the full symmetry is the Yangian \(Y(gl(N))\), but the space of states with particle number less than \(p\) is a representation of the \(W(gl(Np), p.sl(N))\) algebra \[2\].

The connection between Yangians and finite \(W(sl(Np), N.sl(p))\)-algebras was proven in the Drinfeld presentation \[3\] of the Yangian. Since the homomorphism is (obviously) not an isomorphism, it does not allow to carry the Yangian R-matrix ”down” to the finite \(W\)-algebras. In this paper, we prove the correspondence in the ”RTT” presentation \[4\] of the Yangian. The mentioned finite \(W\)-algebras \[\ast\] appear to be ”truncation” of the Yangian, i.e. the resulting coset when modding out the Yangian ”high level” generators. These truncated Yangians were already introduced in \[5\] under the name of Yangian of level \(p\). Thanks to this presentation, we can deduce a R-matrix for the \(W\)-algebras under consideration, as well as the complete classification of the finite-dimensional irreducible representations of these algebras. We also show that the Hopf structure of the Yangian cannot be carried by the homomorphism: although this is not a ”no-go theorem” for \(W\)-algebras to be Hopf algebras, it severely constrains the possibilities to get this structure.

To prove our result, we need to combine three notions: Yangians, \(W\)-algebras and cohomology. We have tried to be self-contained, and as such, we need to recall known results for these different fields: it is done in section \[2\] for Yangians, in section \[3\] for \(W\)-algebras, and in the appendix \[\mathbb{B}\] for cohomology. We collect our results in section \[\mathbb{I}\] and then present applications in section \[\mathbb{A}\]. We conclude with a …conclusion, where possible generalizations and applications of our results are presented (section \[\mathbb{B}\]). Some calculations about \(gl(Np)\) algebras are collected in the appendix \[\mathbb{A}\].

2 Yangians

Yangians can be seen as deformations of loop algebras (based on a simple Lie algebra) and associated to a rational solution to the Yang-Baxter equation. They have been extensively studied, and we refer to \[\mathbb{B}, \mathbb{C}, \mathbb{D}\] and references therein for more details. We will here focus on Yangians based on \(gl(N)\), and recall the basic properties below.

\footnote{More precisely, it is the \(W(gl(Np), N.sl(p))\) algebras which are concerned, we will come back on this slight difference later on.}
2.1 The Yangian $Y(gl(N))$

There is essentially two presentations of $Y(gl(N))$: one based on generators and relations [3] (Serre-Chevalley-type presentation), and the second (closer to integrable systems methods) using the $R$-matrix approach [4] (see also [7, 6] and ref. therein). We use here the last one. The generators of the Yangian are gathered in a single matrix:

$$T(u) = \sum_{n=0}^{\infty} \sum_{i,j=1}^{N} u^{-n} T_{n}^{ij} E_{ij} = \sum_{n=0}^{\infty} u^{-n} T_{n} = \sum_{i,j=1}^{N} T^{ij}(u) E_{ij} \text{ with } T_{0}^{ij} = \delta^{ij}$$

where $u$ is a spectral parameter and $i, j$ indices in the fundamental of $gl(N)$. $E_{ij}$ is the usual $N \times N$ matrix with 1 at position $(i, j)$. The algebraic structure is encoded in the relation

$$R(u - v)T_{1}(u)T_{2}(v) = T_{2}(v)T_{1}(u)R(u - v)$$

with $R(x) = 1 \otimes 1 - 1 \otimes x P_{12}$ and $P_{12}$ is the flip operator ($P_{12} = \sum_{i,j=1}^{N} E_{ij} \otimes E_{ji}$ in representations). The commutation relations read in components

$$[T_{m}^{ij}, T_{n}^{kl}] = \min(m,n)-1 \sum_{r=0}^{\min(m,n)-1} (T_{r}^{k}T_{m+n-r-1}^{il}-T_{m+n-r-1}^{k}T_{r}^{il})$$

Note that in (2.3), all the couples $(r, s)$, where $s = m+n-1-r$, satisfy $s < \min(m,n)$ and $r \geq \max(m,n)$.

It is known that the Yangian $Y(N)$ is a deformation of a loop algebra based on $gl(N)$. The parameter $\hbar$ can be recovered by multiplying the generators by an appropriate power of $\hbar$:

$$T_{n}^{ij} \rightarrow \hbar^{n-1}T_{n}^{ij}$$

Then, the relations (2.3) can be rewritten as

$$[T_{m}^{ij}, T_{n}^{kl}] = \delta^{ij}T_{m+n-1}^{il} - \delta^{il}T_{m+n-1}^{kj} + o(\hbar)$$

which shows that $Y(N)$ is a deformation of a loop algebra (restricted to its positive modes). It can be proven that as soon as $\hbar \neq 0$, all the Hopf algebras $Y_{h}(N)$ are isomorphic.

The Hopf structure is given by

$$\Delta(T(u)) = T(u) \otimes T(u) \; ; \; \epsilon(T(u)) = 1 \; ; \; S(T(u)) = -T(u)$$

or in components:

$$\Delta(T_{m}^{ij}) = \sum_{k=1}^{N} \sum_{r=0}^{m} T_{r}^{ik} \otimes T_{m-r}^{kj} \; ; \; \epsilon(T_{m}^{ij}) = \delta_{m,0}\delta_{i,j} \; ; \; S(T_{m}^{ij}) = -T_{m}^{ij}$$

For briefness, we will denote $Y(N) \equiv Y(gl(N))$. 

3
2.2 Center of $Y(N)$ and associated Hopf subalgebras.

The center $D = \mathcal{U}(d_i, \ i \in \mathbb{N})$ of $Y(N)$ is generated by the quantum determinant:

$$q\text{-det}(T(u)) \equiv \sum_{\sigma \in \pm} \text{sgn}(\sigma) T_{\sigma(1)1}(u) T_{\sigma(2)2}(u-1) \cdots T_{\sigma(N)N}(u-N+1) = 1 + \sum_{n=1}^{\infty} u^{-n} d_n \quad (2.8)$$

The Hopf algebra $Y(sl(N))$ is the quotient of $Y(N)$ by the relation $q\text{-det}T = 1$, i.e. $Y(sl(N)) \sim Y(N)/D$.

We introduce

$$D_r = \mathcal{U}(\{d_1, d_2, \ldots, d_r\})$$

It is not difficult to show that for any value of $r$, $D_r$ is a Hopf ideal of $Y(N)$. It is obviously an algebra ideal (because it lies in the center of the Yangian), and from (2.7), one shows that

$$\Delta(D_r) \subset D_r \otimes D_r \Rightarrow \Delta(D_r) \subset D_r \otimes Y(N) \oplus Y(N) \otimes D_r \quad (2.9)$$

hence $D_r$ is a coideal. Consequently, the coset $Y(N)/D_r$ is also a Hopf algebra.

$$S_rY(N) = Y(N)/D_r \text{ and } Y(N) \sim S_rY(N) \otimes D_r \quad (2.10)$$

This allows us to construct a series of Hopf subalgebras:

$$S_rY(N) = Y(N)/D_r \text{ and } Y(N) \sim S_rY(N) \otimes D_r \forall r$$

$$Y(N) \equiv S_0Y(N) \supset S_1Y(N) \supset \cdots \supset S_rY(N) \cdots \supset S_\infty Y(N) \equiv Y(sl(N))$$

where $Y(sl(N))$ is the only one which possesses a trivial center. The intermediate subalgebras will be of some use in the following.

2.3 Evaluation representations

The finite dimensional irreducible representations of $Y(N)$ have been classified [8, 9], see also [3, 10] for more details. It uses the notion of evaluation representations [11, 12]:

**Definition 2.1 Evaluation representations**

An evaluation representation $ev_\pi$ is a morphism from the Yangian $Y(gl(N))$ to a highest weight irreducible representation $\pi$ of $gl(N)$. The morphism is given by

$$ev_\pi(T_{ij}^{(1)}) = \pi(T_{ij}^{(1)}) \quad \text{and} \quad ev_\pi(T_{ij}^{(n)}) = 0, \ n > 1 \quad (2.11)$$

where we have identified the generators $T_{ij}^{(1)}$ with $gl(N)$ elements.

The evaluation representations form a very simple class of representations, since only one kind of Yangian generators is non-trivially represented. They are sufficient to get all finite-dimensional irreducible representations, through the tensor products of such representations:
Definition 2.2 Tensor product of evaluation representations

Let \( \{ ev_{\pi_i} \}_{i=1,\ldots,n} \) be a set of evaluation representations. The tensor product of these \( n \) representations \( ev_{\vec{\pi}} = ev_{\pi_1} \otimes \ldots \otimes ev_{\pi_n} \) is a morphism from the Yangian \( Y(gl(N)) \) to the tensor product of \( gl(N) \) representations \( \vec{\pi} = \otimes_i \pi_i \) given by

\[
ev_{\vec{\pi}}(T_{(r)}) = \bigoplus_{r_1 + r_2 + \ldots + r_n = r} \left( \prod_{k=1}^{n} ev_{\pi_k}(T_{(r_k)}) \right) \quad (2.12)
\]

It satisfies:

\[
ev_{\vec{\pi}}(T_{(r)}) \neq 0 \text{ if and only if } r \leq n \quad (2.13)
\]

Note that this definition follows from the Yangian coproduct (2.6). Tensor product of evaluation representations play an important role in the classification of finite dimensional irreducible representations of Yangians. This is reflected in the following theorems and corollary (proved in [8], see also [10, 13, 9] for more details).

**Theorem:** Any finite dimensional irreducible representation of \( Y(N) \) is highest weight and contains (up to multiplication by a scalar) a unique highest weight vector.

By highest weight vector, we mean a vector \( \eta \) (in the representation) such that

\[
t^{ij}(u)\eta = 0 \quad 1 \leq i < j \leq N
\]

\[
t^{ii}(u)\eta = \lambda^i(u)\eta \quad 1 \leq i \leq N
\]

where \( \lambda^i(u) = 1 + \sum_{r>0} \lambda^i_{(r)} u^{-r} \), with \( \lambda^i_{(r)} \in \mathbb{C} \), and \( t^{ij}(u) \) represents \( T^{ij}(u) \). As usual, \( \lambda(u) = (\lambda^1(u), \ldots, \lambda^N(u)) \) is called the weight of the representation.

**Theorem:** An irreducible highest weight representation of \( Y(N) \) of weight \( \lambda(u) \) is finite dimensional if and only if there exist \( (N-1) \) monic polynomials \( P_i(u) \) such that

\[
\frac{\lambda^i(u)}{\lambda^{i+1}(u)} = \frac{P_i(u+1)}{P_i(u)}
\]

In that case, the representation is isomorphic to the subquotient of the tensor product of \( m = \sum_i m_i \) evaluation representations, where \( m_i \) is the degree of \( P_i(u) \).

By monic polynomials we mean a polynomial of the form

\[
P_i(u) = \prod_{k=1}^{m_i} (u - \gamma_k) \quad \text{with} \quad \gamma_k \in \mathbb{C}
\]

By subquotient, we mean the irreducible part of the highest weight submodule of the mentioned tensor product. More precisely, in the tensor product of evaluation representations (which are by definition highest weight representations), one considers the submodule
generated by the tensor product of the highest weight vectors, and quotients it by all (sub)singular vectors which may appear.

Note that although generically the tensor product is irreducible (i.e. is equal to the mentioned submodule and has no singular vector), it is only for $Y(2)$ that it is always irreducible (see counter-example for $Y(3)$ in \[14\]).

A simpler characterization of the finite dimensional irreducible representations is given by the following corollary

**Corollary** The irreducible finite dimensional representations of $Y(N)$ are in one-to-one correspondence with the families \( \{P_1(u), \ldots, P_{N-1}(u), \rho(u)\} \) where $P_i$ are monic polynomials and $\rho(u) = 1 + \sum_{n>0} d_n u^{-n}$ encodes the values of the central elements.

### 2.4 Truncated Yangians

The notion of truncated Yangians has been already introduced in \[5\] (although not named truncated, but Yangian of level $p$) as a tool in representation theory. They were also studied in \[14\]. We now introduce the left ideal generated by $T_p = U(\{T_{ij}^m, n > p\})$:

\[ I_p = Y(N) \cdot T_p \]

and the coset (truncation of the Yangian at order $p$)

\[ Y(N)_p = Y(N)/I_p \]

**Property 2.3** The truncated Yangian $Y(N)_p$ is an algebra ($\forall N \in \mathbb{N}$, $\forall p \in \mathbb{N}$). $\Delta$ is not a morphism of this algebra (for the structure induced by $Y(N)$).

**Proof:** We prove the Lie algebra structure of $Y(N)_p$ by showing that $T_p$ is a bilateral ideal, i.e. that we have $Y(N) \cdot I_p \subset I_p$. In fact, we will show a more stronger property, that is

\[ [Y(N), T_p] \subset Y(N) \cdot T_p \quad \text{and} \quad [Y(N), T_p] \subset T_p \cdot Y(N) \quad (2.15) \]

We make the calculation for the first inclusion, the proof for the other inclusion being identical. Indeed, the relation (2.3) shows that $[T_{ij}^m, T_{kl}^n]$ (for $n > p$) is the sum of two terms, the first being in $Y(N) \cdot T_p$, the second belonging to $T_p \cdot Y(N)$. Focusing on the latter, one rewrites it as

\[ \begin{align*}
\sum_{r=0}^{\min-1} T_{m+n-1-r}^{kl} T_r^{kj} &= \sum_{r=0}^{\min-1} \left( T_r^{kl} T_{m+n-1-r}^{kj} + \sum_{s=0}^{r-1} (T_{m+n-2-s}^{ij} T_{m+n-2-s}^{kl} - T_{m+n-2-s}^{ij} T_{m+n-2-s}^{kl}) \right) \\
&= \sum_{r=0}^{\min-1} T_r^{kl} T_{m+n-1-r}^{kj} + \sum_{s=0}^{\min-2} (\min - s - 1) (T_{m+n-2-s}^{ij} T_{m+n-2-s}^{kl} - T_{m+n-2-s}^{ij} T_{m+n-2-s}^{kl})
\end{align*} \quad (2.16) \]
where \( \min \) stands for \( \min(m, n) \). In (2.16), only the last term belongs to \( T_p \cdot Y(N) \), with a summation which has one term less than the previous one: we can thus proceed recursively in a finite number of steps. The final result is an element of \( Y(N) \cdot T_p \).

As far as Hopf structure is concerned, the calculation

\[
\Delta(T_{p+1}^i) = T_{p+1}^i \otimes 1 + 1 \otimes T_{p+1}^i + \sum_{n=1}^{p} T_n^i \otimes T_{p+1-n}^k
\]

shows that \( \mathcal{I}_p \) is not a coideal, since we have

\[\Delta(\mathcal{I}_p) \not\subset Y(N) \otimes \mathcal{I}_p \oplus \mathcal{I}_p \otimes Y(N)\]

Moreover, \( \Delta \) is not an algebra morphism anymore, since for instance

\[
\Delta \left( \sum_{s+t=p} (T_{s+1}^i \otimes T_t^k - T_s^i \otimes T_{t+1}^k) \right) = 0
\]

Finally, we note that each \( Y(N)_p \) is a deformation of a truncated loop algebra based on \( gl(N) \). By truncated loop algebra, we mean the quotient of a usual \( gl(N) \) loop algebra (of generators \( t_{ij}^n \)) by the relations \( t_{ij}^n = 0 \) for \( n < 0 \) and \( n > p \). The construction is the same as for the complete Yangian.

### 2.5 Poisson Yangians

In the following we will deal with a Poisson version of the Yangian, where the commutator is replaced by Poisson bracket. It corresponds to the usual classical limit of quantum groups. One sets

\[
T(u) = L(u) ; \quad R_{12}(x) = 1 + h r_{12}(x) + o(h) ; \quad [T_{ij}^m, T_{kl}^n] = \min(m, n) - 1 \sum_{r=0}^{\min(m, n)-1} (T_{m+n-r-1}^k T_{r}^i T_{m+n-r-1}^j - T_{m+n-r-1}^j T_{r}^i T_{m+n-r-1}^k)
\]

Apart from the change from commutators to Poisson brackets (and the commutativity of the product), all the above algebraic properties still apply.

In particular, we can still define the truncated (Poisson) Yangian, with the same procedure as above.
3 \( \mathcal{W} \)-algebras

Such algebras can be constructed by symplectic reduction of finite dimensional Lie algebras in the same way the conformal (affine) \( \mathcal{W} \)-algebras arise as reduction of Kac-Moody (affine) Lie algebras, hence the name finite \( \mathcal{W} \)-algebras for the former. Some properties of such \( \mathcal{W} \)-algebras have been developed. In particular, starting from a simple Lie algebra \( G \), a large class of \( \mathcal{W} \)-algebras can be seen as the commutant, in a localization of the enveloping algebra \( U(G) \), of a \( G \)-subalgebra. This feature has already been exploited in various physical contexts. A remarkable fact is that the involved \( \mathcal{W} \)-algebras are just of the type \( \mathcal{W}(\mathfrak{sl}(2n), n, \mathfrak{sl}(2)) \), a subclass of the \( \mathcal{W} \)-\( N_p \), \( N, N_p \) algebras, in which we are interested here.

We note \( \mathcal{W}_p(N) \equiv \mathcal{W}[\mathfrak{gl}(Np), N, \mathfrak{sl}(p)] \). This algebra is defined as the Hamiltonian reduction of the enveloping algebra of \( \mathfrak{gl}(Np) \) (see below). In general, the \( \mathcal{W} \)-algebras are defined using semi-simple Lie algebras, but for \( \mathfrak{gl}(m) \), we have the following property:

\[
\mathcal{W}[\mathfrak{gl}(m), H] \equiv \mathcal{W}[\mathfrak{sl}(m) \oplus \mathfrak{gl}(1), H] \equiv \mathcal{W}[\mathfrak{sl}(m), H] \oplus \mathfrak{gl}(1)
\]

which allows to extend the \( \mathcal{W} \)-algebra to \( \mathfrak{gl}(m) \).

Note also that we are dealing with finite \( \mathcal{W} \)-algebra, i.e. the \( \mathfrak{gl}(m) \) algebras we are speaking of are finite dimensional Lie algebras (not their affinization).

We use the notations introduced in the appendix A.

3.1 \( \mathcal{W}_p(N) \) as an Hamiltonian reduction

Following the usual technic (see and for more details), we gather the generators of \( \mathfrak{gl}(Np) \) in a \( (Np) \times (Np) \) matrix:

\[
\mathbb{J} = \sum_{a,b=1}^{N} \sum_{j=0}^{p-1} \sum_{m=-j}^{j} J^{ab}_{jm} M^{jm}_{ab}
\]

where \( M^{jm}_{ab} \) are \( (Np) \times (Np) \) matrices and \( J^{ab}_{jm} \) are in the dual algebra of \( \mathfrak{gl}(Np) \). They obey Poisson Brackets (PB) which mimic the commutation relations of \( \mathfrak{gl}(Np) \):

\[
\{ J^{j,m}_{ab}, J^{\ell,n}_{cd} \} = \sum_{r=|j-\ell|}^{j+\ell} \sum_{s=-r}^{r} \left( \delta_{bc} < j, m; \ell, n | r, s > J^{r,s}_{ad} - \delta_{ad} < \ell, n; j, m | r, s > J^{r,s}_{cb} \right)
\]

On the dual algebra, we introduce first class constraints:

\[
\mathbb{J}_{|\text{const.}} = \epsilon_- + \sum_{a,b=1}^{N} \sum_{j=0}^{p-1} \sum_{m=0}^{j} J^{ab}_{jm} M^{jm}_{ab} \equiv \epsilon_- + \mathbb{B}
\]

Explicitly, these constraints are imposed on the negative grade generators \( J^{ab}_{jm}, m < 0 \), \( \forall j, a, b \). They correspond to the vanishing of all these negative grade generators, but \( J^{0}_{1,-1} \)
which is set to 1. We will denote them generically by $\phi_x$. Physically, these first class constraints generate gauge transformations, an infinitesimal form of which is:

$$\delta_\lambda J_{jm}^{ab} \sim \sum_x \lambda_x \{\phi_x, J_{jm}^{ab}\} \quad (3.4)$$

where the symbol $\sim$ means that one has to impose the constraints once the PB has been computed. The interesting quantities are the gauge invariant ones, and it can be shown that a way to construct a basis for them is to choose a gauge fixing for $J|_{\text{const.}}$. In the present case, the gauge fixing is the highest weight gauge:

$$J|_{\text{g.f.}} = \epsilon_+ + \sum_{a,b=1}^N \sum_{j=0}^{p-1} W_{ab}^{jj} M_{ab}^{jj} \equiv \epsilon_+ + W \quad (3.5)$$

where $W_{ab}^{jj}$ are the (unknown) generators of the gauge invariant polynomials.

In other words, there is a unique set of parameters $\lambda_x$ such that the gauge transformations (3.4) leads $J|_{\text{g.f.}}$ to $J|_{\text{const.}}$. These parameters are polynomials in the original $J_{jm}^{ab}$, hence the generators $W_{jj}^{ab}$. Since they generate the gauge invariant polynomials, the $W_{jj}^{ab}$'s close ( polynomially) under the PB; they generate the $W(gl(Np), N.sl(p))$ algebra. The Lie algebra structure of this $W$-algebra is given by the PB (3.2), together with the knowledge of the polynomials $W_{jj}^{ab}$. Unfortunately, the complete expression of these polynomials is difficult to obtain in the general case, so that different technics have been developed to compute the PB of the $W$-algebra, without knowing the exact expression of the polynomials $W_{jj}^{ab}$.

There is essentially two different ways of defining the Poisson brackets of the $W_p(N)$ algebras: through the Dirac brackets, or using the so-called soldering procedure. We will need them both, and describe them in the following.

### 3.2 Dirac brackets

It can be shown that the first class constraints together with the gauge fixing form a set of second class constraints, i.e. that if $\Phi = \{\phi_\alpha\}_{\alpha \in I}$ is the set of all constraints, we have

$$\Delta_{\alpha\beta} = \{\phi_\alpha, \phi_\beta\} \text{ is invertible: } \sum_{\gamma \in I} \Delta_{\alpha\gamma} \Delta_{\gamma\beta} = \delta_{\alpha\beta} \quad \text{where } \Delta_{\alpha\beta} \equiv (\Delta^{-1})_{\alpha\beta} \quad (3.6)$$

Together with a set of second class constraints occurs the notion of Dirac brackets which are constructed in such a way that they are compatible with these constraints:

$$\{X, Y\}_{*} \sim \{X, Y\} - \sum_{\alpha, \beta \in I} \{X, \phi_\alpha\} \Delta_{\alpha\beta} \{\phi_\beta, Y\} \quad \forall X, Y \quad (3.7)$$

where the symbol $\sim$ means that one has to apply the constraints on the right hand side once the Poisson Brackets have been computed. The compatibility of the Dirac brackets with the constraints reflects in the following property

$$\{X, \phi_\alpha\}_{*} \sim 0 \quad \forall \alpha \in I, \forall X \quad (3.8)$$
Then, the Poisson brackets of the $\mathcal{W}$-algebra are defined as the Dirac brackets of the unconstrained generators $J_{ij}^{ab}$.

$$\{W_j^{ab}, W_\ell^{cd}\} \equiv \{J_{jj}^{ab}, J_{\ell\ell}^{cd}\}$$ (3.9)

In the case we are considering, the matrix $\Delta$ take the form

$$\Delta_{jm; kl}^{abcd} = \{J_{jm}^{ab}, J_{kl}^{cd}\} \ \forall a, b, c, d, j, k; \ \forall m < j; \ \forall \ell < k$$ (3.10)

$$= (-1)^m j(j+1) - m(m+1) \frac{\eta_j}{\eta_1} \delta_{j,k} \delta_{m+\ell+10,0} \delta_{bc} \delta_{ad} + \frac{1}{2} \sum_{n=0}^{2p-1} \left( \sum_{i=m+1}^{m+n} \eta_i \right)$$ (3.11)

$$= (-1)^m j(j+1) - m(m+1) \frac{\eta_j}{\eta_1} \delta_{j,k} \delta_{m+s+1,0} \delta_{bc} \delta_{ad} \left( 1 - \hat{\Delta} \right)^{cd; ef}_{kl; rs} (3.12)

$$= 2 \eta_1 < j, -m - 1; k, \ell | t, t > \left( \delta_{bc} J_{ad}^{tt} + \left(-1\right)^{j+k+\ell} \eta_j \right)$$ (3.13)

$$= 2 \eta_1 < j, -m - 1; k, \ell | t, t > \left( \delta_{bc} J_{ad}^{tt} + \left(-1\right)^{j+k+\ell} \eta_j \right)$$ (3.14)

The form (3.13) shows that $\Delta$ is invertible, for the matrix $\hat{\Delta}$ is nilpotent: due to the Clebsch-Gordan coefficient $< j, -m - 1; k, \ell | t, t >$, we have $(\hat{\Delta})^{2p-1} = 0$. Hence, we deduce

$$\hat{\Delta}_{ab; cd}^{jm; kl} = (-1)^{m+1} j(j+1) - m(m+1) \frac{\eta_j}{\eta_1} \sum_{n=0}^{2p-1} \left( \hat{\Delta}^n \right)^{ba; cd}_{jm; kl}$$ (3.15)

where we have set

$$(\hat{\Delta})^{0; ab; cd}_{jm; kl} = \delta_{j,k} \delta_{m,\ell} \delta_{ac} \delta_{bd}$$ (3.16)

Once $(\Delta)^{-1}$ is known, one can compute the Dirac brackets. Unfortunately, in practice, (3.15) is difficult to achieve, and only partial results are obtained using the Dirac brackets.

### 3.3 Soldering procedure

The calculation of the Poisson brackets of the $\mathcal{W}$-algebra can be achieved through another way, called the soldering procedure[16], see also [1] in the case of finite $\mathcal{W}$-algebras. It is not our aim to show the equivalence of this approach with the previous (Dirac) procedure. We give here just a flavor of it in the context of $\mathcal{W}_p(N)$-algebras.

In the soldering procedure, the idea is to view the (adjoint) action of the $\mathcal{W}_p(N)$ algebra on itself as a "residual" action of the whole $gl(Np)$ algebra on the currents, residual in the sense that it "respects" the constraints that have been imposed. In other words, among all the transformations induced by the (enveloping algebra of) $gl(Np)$, we look for the ones that do not affect the form $\mathcal{J}_{g,f}$: these will be the transformations induced by the $\mathcal{W}_p(N)$-algebra.

In the present paper, thanks to the basis explicit in the appendix A, we will be able to synthetically present (and solve) this procedure in the case of $\mathcal{W}_p(N)$ algebras.
More precisely, the action of \( gl(Np) \), with parameter \( \lambda = \sum_{j,m;a,b} \lambda_{jm}^{ab} M_{ab}^{jm} \), can be written
\[
\delta_\lambda \mathbb{J} = \{ \text{tr}(\lambda \mathbb{J}), \mathbb{J} \} = [\lambda, \mathbb{J}]
\]  \( (3.17) \)
where \( \{ , \} \) is the PB (on the \( J \)'s) and \([ , ]\) is the commutator (of \( Np \times Np \) matrices). Within all these transformations, we look for the ones which preserve the form of \( \mathbb{J}_{g.f.} \):
\[
\delta_\lambda (\mathbb{J}_{g.f.}) = \delta_\lambda \mathbb{W} = \sum_{j,a,b} (\delta_\lambda J_{jj}^{ab}) M_{ab}^{jj}
\]  \( (3.18) \)
This constrains the parameters \( \lambda_{jm}^{ab} \), and only \( N^2p \) of them are left free: they correspond to the parameters of the \( \mathbb{W} \)-transformation.

Explicitly, the calculation \([\lambda, \epsilon - \mathbb{W}] = \delta_\lambda \mathbb{W}\) leads to
\[
\lambda_{j,m+1} = \sum_{k,r=0}^{p-1} \sum_{\ell = -k}^{k-1} (\lambda^{\ell \ell} W_r < k, \ell; r, r | j, m > - W_r \lambda^{\ell \ell} < r, r; k, \ell | j, m >)
\]  \( (3.19) \)
where \( \lambda_{j,m} = \sum_{a,b} \lambda_{jm}^{ab} M_{ab}^{jm}, W_j = \sum_{a,b} W_{j}^{ab} M_{ab}^{jj} \) and the products are matricial products.

The system \( (3.19) \) is strictly triangular in \( \lambda_{jm} \) with respect to the gradation \( gr(\lambda_{jm}) = j+m \). Indeed, the Clebsch-Gordan coefficients ensure that \( |j-r| \leq k \leq j+r \) and \( \ell+r = m \), so that \( gr(\lambda_{k,\ell}) = k + \ell \leq j + m < j + m + 1 = gr(\lambda_{j,m+1}) = \) in \( (3.19) \). Thus, all the \( \lambda \)'s are expressible in terms of the \( \lambda_{j,-j} \) parameters.

### 3.3.1 Calculation of \( \{ W_0^{ab}, W_{j}^{cd} \} \)
As a start up, we consider the variation of \( W_0 \). In that case, one has only to look at \( (3.20) \), which reads:
\[
\delta_\lambda W_0 = \sum_{k,r=0}^{p-1} (-1)^k \eta_k [\lambda^{k,-k}, W_r]
\]  \( (3.22) \)
Thus, we get the equation:
\[
\sum_{j} \tilde{\lambda}_j \{ W_j; W_0 \} = \frac{1}{p} \sum_{j} [\tilde{\lambda}_j; W_r]
\]  \( (3.23) \)
where \( \tilde{\lambda}_j = (-1)^j \eta_j \lambda_{j,-j} \). Hence, we are directly led to the PB:
\[
\{ W_0^{ab}, W_{j}^{cd} \} = \frac{1}{p} (\delta^{bc} W_j^{ad} - \delta^{ad} W_j^{bc})
\]  \( (3.24) \)
3.3.2 Calculation of $\{W_1^{ab}, W_2^{cd}\}$

Now, focusing on the variation of $W_1$ and using the results (A.23-A.28), we are led to

$$\delta_\lambda W_1 = \sum_j c_j \left( \frac{1}{j(2j - 1)} [\lambda_{j-1,1-j}, W_j] - [\lambda_{j,1-j}, W_j]_+ + \frac{(j + 1)(p - j - 1)(p + j + 1)}{2j + 3} [\lambda_{j+1,1-j}, W_j] \right)$$

where $c_j$ has been defined in (A.23) and $[\cdot, \cdot]$ (resp. $[\cdot, \cdot]_+$) stands for the commutator (anti-commutator) of $Np x Np$ matrices. Then, solving the equation (3.19) for $m = -j, 1 - j$, and plugging the result into (3.25) gives

$$\sum_j \tilde{\lambda}_j \{W_j, W_1\} = \frac{3}{p(p^2 - 1)} \left( \sum_{j=1}^{p-1} j(p^2 - j^2) \frac{1}{2j + 1} [\tilde{\lambda}_{j-1}, W_j] + \sum_{j=1}^{p-1} \sum_{s=j}^{p-1} \left( [\tilde{\lambda}_s, W_{s-j}], W_j \right)_+ \right. $$

$$\left. + \sum_{j=0}^{p-1} \sum_{s=j+1}^{p-1} \frac{s - j - 1}{2j + 1} \left( [\tilde{\lambda}_{s-1}, W_{s-j-1}], W_j \right)_+ \right)$$

$$\left. - \sum_{j=0}^{p-1} \sum_{s=j+1}^{p-1} \sum_{t=j+1}^{p-1} \frac{1}{t(2j + 1)} \left( [\tilde{\lambda}_s, W_{s-t}], W_{t+1-j}, W_j \right) \right)$$

In component, we get the following PB:

$$\{W_1^{ab}, W_2^{cd}\} = \frac{3}{p(p^2 - 1)} \left( \frac{(j + 1)(p^2 - (j + 1)^2)}{2j + 3} \left( \delta^{cb} W_{j+1}^{ad} - \delta^{ad} W_{j+1}^{cb} \right) + j \left( \delta^{cb} (W_0 W_j)^{ad} - \delta^{ad} (W_j W_0)^{cb} + W_j^{cb} W_0^{ad} - W_j^{ad} W_0^{cb} \right) + \right)$$

$$\sum_{s=1}^{j} \left( 1 + \frac{j - s}{2s + 1} \right) \left( \delta^{cb} (W_s W_{j-s})^{ad} - \delta^{ad} (W_{j-s} W_s)^{cb} \right) +$$

$$\sum_{s=1}^{j} \left( 1 - \frac{j - s}{2s + 1} \right) \left( W_{j-s}^{ad} W_s^{cb} - W_s^{ad} W_{j-s}^{cb} \right) +$$

$$- \sum_{s=0}^{j-1} \sum_{t=s+1}^{j} \frac{1}{t(2s + 1)} \left( \delta^{cb} (W_s W_{t-s-1} W_{j-t})^{ad} - \delta^{ad} (W_{j-t} W_{t-s-1} W_s)^{cb} + \right. $$

$$\left. + W_{j-t}^{ad} (W_{t-s-1} W_s)^{cb} - (W_s W_{t-s-1})^{ad} W_{j-t}^{cb} + \right)$$

$$\left. + W_{t-s-1}^{ad} (W_{j-t} W_s)^{cb} - (W_s W_{j-t})^{ad} W_{t-s-1}^{cb} + \right)$$

$$\left. + W_{s}^{ad} (W_{j-t} W_{t-s-1})^{cb} - (W_{t-s-1} W_{j-t})^{ad} W_s^{cb} \right) \right)$$

12
Comparison between truncated Yangians and finite $\mathcal{W}$-algebras

We have seen that the truncated Yangians are a deformation of a truncated loop algebra based on $gl(N)$. We show below that $\mathcal{W}_p(N)$ is also a deformation of this algebra, and that these two deformations coincide. We use here the notions presented in appendix B. We work at the classical (Poisson brackets) level.

4.1 $\mathcal{W}_p(N)$ as a deformation of a truncated loop algebra

To see that the $\mathcal{W}_p(N)$ is a deformation of a truncated loop algebra based on $gl(N)$, we modify the constraints to

$$J = \frac{1}{\hbar} \epsilon - \sum_{a,b=1}^{N} \sum_{j=0}^{p-1} \sum_{0 \leq m \leq j} J_{jm}^a M_{ab}^m$$

These constraints are equivalent to the previous ones as soon as $\hbar \neq 0$. With these new constraints, the matrix $\Delta$ and its inverse read

$$\Delta_{ab}^j = \frac{1}{\hbar} (-1)^m \frac{j(j+1) - m(m+1)}{2} \eta_{j,k} \delta_{m+\ell+1;0} \delta_{bc}$$

$$\tilde{\Delta}_{ab}^j = \hbar (-1)^{m+1} \frac{j(j+1) - m(m+1)}{2} \eta_{j} \sum_{n=0}^{2p-1} \hbar^n \tilde{\Delta}_{ab}^j$$

Then, computing the Dirac brackets associated to these new constraints, one finds

$$\{ J_{jj}^a, J_{\ell\ell}^c \} = \sum_{efgh;kmrs} \{ J_{jj}^a, J_{\ell\ell}^f \} (\tilde{\Delta}_{ab}^j)^{km;rs} \{ J_{gh}^c, J_{\ell\ell}^d \}$$

$$ = \delta_{bc} J_{j+\ell, j+\ell} - \delta_{ad} J_{j+\ell, j+\ell} - \hbar P(J)$$

where $P(J)$ (polynomial in the $J_{jj}^a$ which is computed using $\tilde{\Delta}_h$ as in section 3.2) has only positive (or null) powers of $\hbar$. This clearly shows that the $\mathcal{W}_p(N)$ algebra is a deformation of the algebra generated by $W_{jj}^a \equiv J_{jj}^a$ and with defining (undeformed) Poisson brackets:

$$\{ W_{jj}^a, W_{\ell\ell}^c \} = \delta_{bc} W_{j+\ell}^a - \delta_{ad} W_{j+\ell}^c$$

One recognizes in this algebra a (enveloping) loop algebra based on $gl(N)$ quotiented by the relations $W_{jj}^a = 0$ if $j \geq p$. In other words, this algebra is nothing but a truncated loop algebra, and the $\mathcal{W}$-algebra is a deformation of it.
4.2 Identification of $\mathcal{W}_p(N)$ and $Y(N)_p$

We have already seen that the truncated Yangians as well as the $\mathcal{W}$-algebras we consider are both a deformation of a truncated loop algebra:

\[
\{W_{j}^{ab}, W_{\ell}^{cd}\}_1 = \{W_{j}^{ab}, W_{\ell}^{cd}\}_0 + \sum_{n=1}^{\infty} h^n \phi_n(W_{j}^{ab}, W_{\ell}^{cd}) \quad 0 \leq j, \ell \leq p-1
\]

\[
\{\bar{T}_{ij}^{kl}, \bar{T}_{kl}^{mn}\}_2 = \{\bar{T}_{ij}^{kl}, \bar{T}_{kl}^{mn}\}_0 + \sum_{r=1}^{\infty} \bar{h}^r \phi_r(\bar{T}_{ij}^{kl}, \bar{T}_{kl}^{mn}) \quad 0 \leq m, n \leq p-1
\]

where the cochains $\phi_n$ and $\phi_r$ obey (3.40)-(3.41). The undeformed PB $\{ , \}$ are identical (via the identification $W_{j}^{ab} \equiv \bar{T}_{ij}^{kl}$) and correspond to the truncated loop algebra. Thus, we have two deformed PB $\{ , \}_1$ and $\{ , \}_2$, and all we need is to show that the cochains $\phi_n$ and $\phi_r$ coincide $\forall n$. To prove that it is indeed the case, we need the following properties:

**Lemma 4.1** Let $gl(N)_p$ be the loop algebra based on $gl(N)$, truncated at order $p$, and $u_{j}^{ab}$ $(j < p)$ the corresponding generators. A 2-cocycle $\phi$ with values in $U(gl(N)_p)$ is completely determined once one knows $\phi(u_{0}^{ab}, u_{j}^{cd})$ and $\phi(u_{1}^{ab}, u_{j}^{cd})$, $\forall a, b, c, d = 1, \ldots, N$ and $\forall j = 0, \ldots, p-1$.

**Proof:** We prove this lemma recursively. We write the cocycle condition for a triplet $(u_A^1, u_B^1, u_C^1)$, using indices $A, B, C = 1, \ldots, N^2$ in the adjoint representation, and the commutation relations of $gl(N)_p$:

\[
f_{AB}^{CD} \phi(u_{1+j}^A, u_k^C) + f_{BC}^{CD} \phi(u_{k+j}^D, u_1^A) + f_{CA}^{CD} \phi(u_{k+j}^D, u_1^B) = \{u_1^A, \phi(u_j^B, u_k^C)\} + \{u_j^B, \phi(u_k^C, u_1^A)\} + \{u_k^C, \phi(u_1^A, u_j^B)\}
\]

It can be rewritten as

\[
\gamma_2 \phi(u_{1+j}^A, u_k^B) = f_{CD}^{AB} f_{DB}^{CE} \phi(u_1^C, u_{k+j}^E) + f_{CD}^{AB} f_{DB}^{CE} \phi(u_j^C, u_{k+1}^E) + f_{CD}^{AB} \left( \{u_k^B, \phi(u_j^C, u_1^D)\} + \{u_j^C, \phi(u_k^D, u_1^B)\} + \{u_1^D, \phi(u_k^B, u_j^C)\} \right)
\]

where $\gamma_2 \neq 0$ is the value of the second Casimir operator in the adjoint representation.

For $j = 1$, (4.11) allows to compute $\phi(u_2^D, u_k^C) \forall C, D$ and $\forall k \geq 1$ once $\phi(u_1^D, u_k^C) \forall C, D$ and $\forall k$ is known.

Suppose now that we know $\phi(u_j^a, u_k^b)$ for $1 \leq j < \ell_0$ and $\forall k$. Then, (4.11) for $j = \ell_0-1$ allows to compute $\phi(u_{\ell_0}^a, u_k^b) \forall k$.

Thus, apart from the values $\phi(u_0^a, u_k^b)$ we are able to compute all the expressions $\phi(u_j^a, u_k^b)$. This ends the proof.

\[\text{The shift } j \to j - 1 \text{ in the identification is due to a difference of convention between } \mathcal{W}\text{-algebras and Yangians: in the former case, the index } j \text{ denotes the underlying } sl(2) \text{ representation, while in the latter } j \text{ is the exponent of } u \text{ in the formal series } \hat{2}.\]
Property 4.2 There exist two sets of generators \( \{ \pm W_{j1}^{ab} \}_{j=0,\ldots} \) in \( W_p(N) \) such that

\[
\{ \pm W_{1}^{ab} , \pm W_{j1}^{cd} \} = \delta^{cb} \pm W_{j1}^{ad} - \delta^{ad} \pm W_{j1}^{cb} + W_{0}^{cb} \pm W_{j1}^{ad} - \pm W_{j1}^{cb} W_{0}^{ad}
\]

\( \forall a,b,c,d = 1,\ldots,N \), \( \forall j \geq 1 \)

\( \{ W_{0}^{ab} , \pm W_{j1}^{cd} \} = \delta^{cb} \pm W_{j1}^{ad} - \delta^{ad} \pm W_{j1}^{cb} \)

The generators \( \pm W_{j1}^{ab} \) are polynomial of degree \( (j+1) \) in the original ones \( W_{j1}^{ab} \) and are recursively defined by

\[
\pm W_{j1}^{ab} = \sum_{n=1}^{j+1} \pm W_{j1(n)}^{ab} = \sum_{n=1}^{j+1} \sum_{|\bar{s}|=j1-n} \pm \alpha_{\bar{s}}^{n,j} (W_{s1} \cdots W_{sn})^{ab} 1 < n \text{ and } 1 < j
\]

\[
\pm W_{1}^{ab} = \pm p(p^2 - 1) W_{1}^{ab} + \frac{p(p + 1)}{2} (W_{0}^{ab})
\]

\( W_{0}^{ab} \equiv + W_{0}^{ab} = - W_{0}^{ab} = p W_{0}^{ab} \)

for some numbers \( \pm \alpha_{\bar{s}}^{n,j} \). The summation on \( \bar{s} \) is understood as a summation on \( n \) positive (or null) integers \( (s_1, \ldots, s_n) \equiv \bar{s} \) such that \( |\bar{s}| = \sum_{i=1}^{m} s_i = j + 1 - n \).

The subsets \( \{ \pm W_{j1}^{ab} \}_{j=0,\ldots,p-1} \) form two bases of \( W_p(N) \), the other generators \( \{ \pm W_{j1}^{ab} \}_{j\geq p} \) been polynomials in the basis elements.

Proof: We first remark that the form (4.12) clearly shows that the \( p \) first generators are independent, and thus form a basis. The other ones must then be polynomials in any basis.

We prove the relation (4.11) by a recursion on \( j \). It is easy to compute that the definitions are such that (4.11) is satisfied for \( j = 1 \). For the recursion, we fix a basis \( + W_{j1}^{ab} \) or \( - W_{j1}^{ab} \) (the proof is obviously independent of the choice), and write it \( \tilde{W}_{j1}^{ab} \).

We suppose that we have found generators \( W_{j1}^{ab} \) for \( j \leq j_0 \) such that (4.11) is satisfied. This implies that we have:

\[
N \tilde{W}_{j1+1}^{cd} = \{ \tilde{W}_{1}^{ca}, \tilde{W}_{j0}^{ad} \} - \tilde{W}_{0}^{ra} \tilde{W}_{j0}^{ra} + \tilde{W}_{0}^{cd} \tilde{W}_{j0}^{ra} + \delta_{cd} \tilde{W}_{j0}^{ra}
\]

where we have used implicit summation on repeated \( gl(N) \) indices. Then, we get

\[
N \{ \tilde{W}_{1}^{ab}, \tilde{W}_{j0+1}^{cd} \} = \{ \tilde{W}_{1}^{ab}, \tilde{W}_{j0+1}^{cd} \} - \tilde{W}_{0}^{ra} \tilde{W}_{j0+1}^{ra} + \tilde{W}_{0}^{cd} \tilde{W}_{j0+1}^{ra} + \delta_{cd} \tilde{W}_{j0+1}^{ra}
\]

\[
= \{ \{ \tilde{W}_{1}^{ab}, \tilde{W}_{j0+1}^{cd} \} + \tilde{W}_{1}^{cd} \tilde{W}_{j0+1}^{ra} + \delta_{cd} \tilde{W}_{j0+1}^{ra} \} + \\tilde{W}_{0}^{cd} \tilde{W}_{j0+1}^{ra} + \delta_{cd} \tilde{W}_{j0+1}^{ra}
\]

\[
= \{ \tilde{W}_{1}^{cb} \tilde{W}_{j0+1}^{ad} - \tilde{W}_{1}^{cb} \tilde{W}_{j0+1}^{ad} \} + \\tilde{W}_{0}^{cd} \tilde{W}_{j0+1}^{ra} + \delta_{cd} A^{ad} - \delta_{ad} B^{cb} + \delta_{cd} C^{ab}
\]

with the notation

\[
A^{ad} = \{ \tilde{W}_{1}^{ae}, \tilde{W}_{j0+1}^{cd} \} + \tilde{W}_{0}^{ra} \tilde{W}_{j0+1}^{ra} - \tilde{W}_{0}^{ee} \tilde{W}_{j0+1}^{ra} + \tilde{W}_{1}^{ad} \tilde{W}_{j0+1}^{ee} - \tilde{W}_{0}^{ee} \tilde{W}_{j0+1}^{ra}
\]

\[
B^{cb} = \{ \tilde{W}_{1}^{ce}, \tilde{W}_{j0+1}^{cb} \} + \tilde{W}_{0}^{cb} \tilde{W}_{j0+1}^{ee} - \tilde{W}_{0}^{ee} \tilde{W}_{j0+1}^{cb}
\]

\[
C^{ab} = \{ \tilde{W}_{1}^{ab}, \tilde{W}_{j0+1}^{ee} \} + [\tilde{W}_{0}, \tilde{W}_{j0+1}]^{ab}
\]
It remains to compute \( \{ \bar{W}^{cb} \}, \bar{W}^{ad} \). This is done using the same technics as above:

\[
N \bar{W}^{cb} = \{ \bar{W}^{ab}, \bar{W}^{cd} \} - \bar{W}^{ac} \bar{W}^{cb} + \bar{W}^{cb} \bar{W}^{ac} + \delta^{cb} \bar{W}^{ac}
\]

so that we have

\[
N \{ \bar{W}^{cb} , \bar{W}^{ad} \} = - (\{ \bar{W}^{ab} , \bar{W}^{cd} \}) + N (\bar{W}^{ab} \bar{W}^{cd} - \bar{W}^{ab} \bar{W}^{cd}) + \delta^{ab} B^{cd} + \delta^{cd} (\{ \bar{W}^{ab} , \bar{W}^{cd} \} - \bar{W}^{ab} \bar{W}^{cd} + \bar{W}^{ab} \bar{W}^{cd}) + \delta^{cb} (\{ \bar{W}^{ab} , \bar{W}^{ad} \} + \bar{W}^{ab} \bar{W}^{ad} - \bar{W}^{ab} \bar{W}^{ad})
\]

Then, a recurrent use of these two brackets leads to the result:

\[
\{ \bar{W}^{ab} , \bar{W}^{cd} \} = \bar{W}^{ab} \bar{W}^{cd} - \bar{W}^{ab} \bar{W}^{cd} + \delta^{cb} \bar{W}^{ab} \bar{W}^{cd} - \delta^{ad} \bar{W}^{ab} \bar{W}^{cd} + \frac{\delta^{ab}}{N(N^2 - 1)} (\{ \bar{W}^{ab} , \bar{W}^{cd} \} - \bar{W}^{ab} \bar{W}^{cd} + \bar{W}^{ab} \bar{W}^{cd}) + \frac{\delta^{cd}}{N} (\{ \bar{W}^{ab} , \bar{W}^{cd} \} + \bar{W}^{ab} \bar{W}^{cd} - \bar{W}^{ab} \bar{W}^{cd}) + \frac{\delta^{bc}}{N(N^2 - 1)} (\{ \bar{W}^{ab} , \bar{W}^{cd} \} - \bar{W}^{ab} \bar{W}^{cd} + \bar{W}^{ab} \bar{W}^{cd})
\]

for some polynomials \( \bar{W}^{ad} \).

Finally, we remark that the forms \( (1.12) \) and the PB \( (3.27) \) clearly show that the PB \( \{ \bar{W}^{ab} , \bar{W}^{cd} \} \) does not contain terms proportional to \( \delta^{ab} \) or \( \delta^{cd} \). Moreover, a direct calculation, using \( (3.27) \), shows that

\[
\{ \bar{W}^{ab} , \bar{W}^{cd} \} = 0, \quad \forall \ P^{cd}(W) = \sum_{n=1}^{j+1} \sum_{|\vec{n}|=j+1-n} \beta_{\vec{n}}^{s} (W_{s1} \ldots W_{sn})^{cd}
\]

This is enough to show that the two last lines in the PB \( (1.12) \) identically vanish.

Hence, we can deduce that the PB must be of the form

\[
\{ \bar{W}^{ab} , \bar{W}^{cd} \} = \bar{W}^{ab} \bar{W}^{cd} - \bar{W}^{ab} \bar{W}^{cd} + \delta^{cb} \bar{W}^{ab} \bar{W}^{cd} - \delta^{ad} \bar{W}^{ab} \bar{W}^{cd}
\]

which is exactly \( (1.11) \), so that the recursion on \( j \) is proven.

We have computed the first and last terms (\( \forall j \geq 0 \)) that appear in the definition \( (1.12) \):

\[
\pm \bar{W}^{ab}_{j(1)} = (\pm 1)^j (j!)^2 \left( \frac{p+j}{2j+1} \right) W^{ab}_{j}
\]
\[ -\bar{W}_{j,(j+1)}^{ab} = \binom{p}{j+1} (W_0 \cdots W_0)_{j+1}^{ab} \quad (4.17) \]

\[ +\bar{W}_{j,(j+1)}^{ab} = \binom{p+j}{j+1} (W_0 \cdots W_0)_{j+1}^{ab} \quad (4.18) \]

**Corollary 4.3** The change of generators between \(\{+\bar{W}_j^{ab}\}\) and \(\{-\bar{W}_j^{ab}\}\) is given by:

\[ \pm \bar{W}_j^{ab} = \sum_{n=1}^{j} (-1)^{j+n+1} \sum_{|\vec{s}|=j+1-n} (\mp \bar{W}_{s_1} \cdots \mp \bar{W}_{s_n})^{ab} \quad (4.19) \]

**Proof:** Using the expression \((4.12)\) for \(j = 1\) and the PB \((4.11)\), one computes that

\[ \{ \pm \bar{W}_1^{ab}, \mp \bar{W}_{j+1}^{cd} \} = \delta^{bc} (\mp \bar{W}_0 \bar{W}_j)^{ad} - \mp \bar{W}_{j+1}^{ad} \mp \bar{W}_0^{bc} - \mp \bar{W}_j^{cb} \quad (4.20) \]

Then, a direct calculation shows that indeed the expression \((4.19)\) satisfies \((4.11)\).

**Corollary 4.4** The basis \(\{-\bar{W}_j^{ab}\}\) is such that \(-\bar{W}_j^{ab} = 0\) for \(j \geq p\). In the basis \(\{+\bar{W}_j^{ab}\}\), all the \(+\bar{W}_j^{ab}\) generators \((j \geq p)\) are not vanishing.

**Proof:** From the PB \((4.11)\) it is clear that it is sufficient to show that \(\bar{W}_p^{ab} = 0\). Writing this PB for \(j = p\) and using the form

\[ \bar{W}_p^{ab} = \sum_{n=2}^{p+1} \sum_{|\vec{s}|=p+1-n} \alpha^{n,p}_s (\bar{W}_{s_1} \cdots \bar{W}_{s_n})^{ab} \quad (4.21) \]

one gets only two possibilities for the \(\alpha\)’s:

\[ \alpha^{n,p}_s = (-1)^n A \quad \text{with } A = 0 \text{ or } 1 \quad (4.22) \]

If \(A = 0\), then \(\bar{W}_p^{ab} = 0\) while if \(A = 1\), the change of basis given in the corollary \(4.3\) shows that in the other basis we have \(\bar{W}_p^{ab} = 0\). Hence, we have to determine which basis corresponds to \(\bar{W}_p^{ab} = 0\).

Looking at the expressions \((4.18)\) and \((4.17)\), one concludes that \(-\bar{W}_p^{ab} = 0\) while \(+\bar{W}_j^{ab} \neq 0, \forall j\).

In the following, we choose for \(\mathcal{W}_p(N)\) the \(\{-\bar{W}_j^{ab}\}\) basis and omit the superscript \(-\) for the generators. Now, from above, it is easy to show:
Theorem 4.5 The $\mathcal{W}_p(N)$ algebra is the truncated Yangian $Y(N)_p$.

Proof: Let us first remark that the two algebras have identical (in fact undeformed) PB on the couples $(\bar{W}^{ab}_0, \bar{W}^{cd}_j)$, which proves that the cochains $\varphi^W_n$ and $\varphi^T_n$ coincide (in fact vanish) on these points.

Moreover, the property 4.2 shows that the cochains $\varphi^W_n$ and $\varphi^T_n$ coincide on the couples $(\bar{W}^{ab}_1, \bar{W}^{cd}_j)$. Since $\varphi_1$ is a cocycle, this is enough (using lemma 4.1) to prove that $\varphi^T_1$ and $\varphi^W_1$ are identical.

Now, suppose that we have proven that $\varphi^W_n$ and $\varphi^T_n$ are identical for $n < n_0$. Then, eq. (B.41) fixes $\varphi^W_{n_0}$ and $\varphi^T_{n_0}$, up to a cocycle:

$$\varphi^W_{n_0} = \varphi_{n_0} + \xi^W_{n_0}$$
$$\varphi^T_{n_0} = \varphi_{n_0} + \xi^T_{n_0}$$

where $\varphi_{n_0}$ is a function of the cochains $\varphi^W_n = \varphi^T_n$, $n < n_0$. But property 4.2 shows that the two cocycles $\xi^W_{n_0}$ and $\xi^T_{n_0}$ coincide on the couples $(\bar{W}^{ab}_1, \bar{W}^{cd}_j)$, which proves that they are identical (due to lemma 4.1).

Thus, $\varphi^W_{n_0}$ and $\varphi^T_{n_0}$ are identical, and we have proven recursively the property. $lacksquare$

4.2.1 Quantization

We have shown that truncated Yangians and $\mathcal{W}$-algebras coincide at the classical level. It remains to show that it is still true at the quantum level. Fortunately, an algebra morphism between Yangians and $\mathcal{W}$-algebras has already been given in [1], at classical and quantum levels. This relation was not sufficient to establish the identification between $\mathcal{W}$-algebras and truncated Yangians, since all the horizontal arrows involved in the diagram

$$\begin{align*}
Y(N) & \longrightarrow \mathcal{W}_p(N) \\
\Downarrow & \quad \Downarrow ? \\
Y(N) & \longrightarrow Y_p(N)
\end{align*}$$

are not isomorphisms. Hence the calculations done in this paper.

However, once the relation (between $Y_p(N)$ and $\mathcal{W}_p(N)$) has been established at the classical level, we can use the result of [1] to promote it at the quantum level. More precisely, now that we can identify the $\mathcal{W}_p(N)$ algebra with $Y_p(N)$ at the classical level, we can use the results of [1] at the quantum level: it has been established that any quantization of $\mathcal{W}_p(N)$ still obey to the Drinfeld relation, and hence the homomorphism still exists at the quantum level.

Thus, theorem 4.5 is valid both at classical and quantum level, and the figure 4.23 is correct (without question mark).
Let us remark that in the proof we have establish, we have constructed $\mathcal{W}$-algebras as deformations of a truncated loop algebra and identified them with the truncated Yangians, i.e. truncations of deformed loop algebras. Denoting by $\mathcal{L}(gl(N))$ the loop algebra defined on $gl(N)$, and by $\mathcal{L}(gl(N))_p$ its truncation, the above sentence can be pictured as the following commutative diagram:

\[ \begin{array}{ccc}
Y(N) & \rightarrow^p & Y_p(N) \equiv \mathcal{W}_p(N) \\
\mathcal{L}(gl(N)) & \rightarrow^p & \mathcal{L}(gl(N))_p \\
\rightarrow_h & & \rightarrow_h
\end{array} \]

(4.24)

where $\rightarrow_h$ stands for a deformation, and $\rightarrow^p$ for a truncation (at level $p$).

5 Applications

5.1 $R$-matrix for $\mathcal{W}$-algebras

The above construction allows us to associate the $\mathcal{W}$-algebras to the $R$-matrix of the Yangian, the difference between these two algebras lying in the modes development of $T(u)$: in both cases, the development is done in powers of $u^{-1}$, but for the Yangian it is an infinite series, while the development is truncated to a polynomial for the $\mathcal{W}$-algebra. Explicitly, the presentation of the $\mathcal{W}_p(N)$-algebra take the form:

\[
R(u - v)T_1(u)T_2(v) = T_2(v)T_1(u)R(u - v) \quad \text{with} \quad \begin{cases} 
T(u) = 1 + \sum_{n=1}^{p} \sum_{a,b=1}^{N} u^{-n} E_{ab} T_n^{ab} \\
R(x) = 1 \otimes 1 - \frac{1}{x} P_{12}
\end{cases}
\]

Let us remark that this procedure is similar to the "factorization procedure" which leads from the elliptic algebra $A_{q,p}(N)$ to the Sklyanin algebra $S_{q,p}(N)$ [22] (see also [23] for more examples about factorizations). In all cases, one chooses for $T(u)$ a special dependence in $u$ to get a finite algebra: this special dependence is nothing but a coset by some of the modes of $T(u)$. In all the examples, the Hopf structure of the starting algebra does not survive to this quotient.

Note that the $R$-matrix presentation of the $\mathcal{W}$-algebras provides an exhaustive set of commutation relations among the $\mathcal{W}_p(N)$ generators for generic $N$ and $p$, while, up to now, a complete set of commutation relation was known only for a small number of $\mathcal{W}$-algebras.

Let us also remark that the $R$-matrix presentation allows to define the $\mathcal{W}$-algebras without any reference to the underlying $gl(N_p)$ algebra, and thus is a more "abstract" definition.
5.2 Irreducible representations of \( \mathcal{W}_p(N) \)-algebras

Once again, the \( R \)-matrix presentation provides a very natural framework for the classification of \( \mathcal{W} \)-representations\(^\dagger\). It is based on the notion of evaluation representations, as it appears in the Yangian context (see section 2.3). In fact, this classification was done in [5], in the context of (truncated) Yangians. We have the following theorem:

**Theorem 5.1 Finite dimensional irreducible representations of \( \mathcal{W}_p(N) \)**

Any finite dimensional irreducible representation of the \( \mathcal{W}[gl(Np), N.gl(p)] \) algebra is isomorphic to an evaluation representation or to the subquotient of tensor product of at most \( p \) evaluation representations.

**Proof:**
By evaluation representations for \( \mathcal{W}_p(N) \) algebra, we mean the definitions 2.1 and 2.2 with the change \( T_{r_1}^{ab} \to W_{r_1}^{ab} \) (i.e. the evaluation representations of the truncated Yangian). The property (2.13) clearly shows that the (subquotient of) tensor product of \( n \) evaluation representations is a representation of the truncated Yangian as soon as \( n \leq p \). It also shows that if it is irreducible for the Yangian, then it is also irreducible for the truncated Yangian and that they are finite dimensional.

Now conversely, an irreducible representation \( \pi \) of the \( \mathcal{W}_p(N) \) algebra can be lifted to a representation of the whole Yangian by setting \( \pi(T_{r_1}^{ij}) = 0 \) for \( r > n \). It is then obviously irreducible for the Yangian, and thus is isomorphic to the tensor product of evaluation representations.

We remark that the theorem 5.1 allows to construct any (finite dimensional) representation of \( \mathcal{W}_p(N) \) in term of \( p \) representations of \( gl(N) \) (including trivial representations). This is exactly what one obtains from the so-called "Miura transformation" that appears in the context of \( \mathcal{W} \)-algebras. Indeed, this transformation allows to construct a representation of the \( \mathcal{W}(G, H) \)-algebra using representations of \( G_0 \), the zero-grade subalgebra of \( G \). In the case of \( \mathcal{W}_p(N) \), we get \( G_0 = N.gl(p) \), and hence need \( N \) representations of \( gl(p) \), as it is stated in theorem 5.1.

Finally, as for Yangians, we have the following characterization (proved using above theorem and the characterization for Yangians):

**Corollary 5.2** The irreducible finite-dimensional representations of \( \mathcal{W}_p(N) \) are in one-to-one correspondence with the families \( \{P_1(u), \ldots, P_{N-1}(u), \rho(u)\} \) where \( P_i \) are monic polynomials of degree \( m_i \) such that \( \sum_i m_i \leq p \), and \( \rho(u) = 1 + \sum_{n>0} d_n u^{-n} \).

5.3 Generalization to \( S_r Y(N)_p \) truncated Yangians.

As well as we have defined truncated Yangians based on \( Y(N) \), the same construction can be done for each of the \( S_r Y(N) \) Hopf algebras, to construct \( S_r Y(N)_p \) algebras (\( r \leq p \)):

\(^\dagger\)We thank P. Sorba for drawing our attention to this point.
these truncated Yangians will correspond to the quotient of $\mathcal{W}_p(N)$ by $D_r$, which is a part of the $\mathcal{W}_p(N)$-center (see below).

In particular, the $\mathcal{W}(\mathfrak{sl}(Np), N.\mathfrak{sl}(p))$ algebra usually encountered in the literature is nothing but the truncation $S_1Y(N)_p$. For this algebra, one sees that there exist two algebra homomorphisms: $Y(gl(N)) \rightarrow \mathcal{W}(\mathfrak{sl}(Np), N.\mathfrak{sl}(p))$ and $Y(sl(N)) \rightarrow \mathcal{W}(\mathfrak{sl}(Np), N.\mathfrak{sl}(p))$. The second one corresponds to the case given in [1].

More generally, we have the following property:

**Property 5.3** There is an algebra homomorphism from $S_rY(N)_{p+q}$ to $S_{r+s}Y(N)_p$, for any values of $p, q, r, s = 0, 1, \ldots, \infty$.

**Proof:** It is a trivial composition of algebra and Hopf algebra homomorphisms, as it is visualized in figure 1.

---

**Figure 1**: The vertical links $\downarrow$ correspond to the truncations (algebra homomorphisms), while the horizontal links $\Rightarrow$ are associated to coset by central elements (Hopf algebra homomorphisms).
5.3.1 Finite dimensional irreducible representations of $S_rY(N)_p$ algebras

Starting from the theorem 5.1 and using cosets by central elements, it is easy to get

**Corollary 5.4** Any finite-dimensional irreducible representation of the $S_rY(N)_p$ algebra is obtained from the subquotient of tensor product of at most $p$ evaluation representations, quotiented by $r$ constraints on the generators of $D_r$.

The finite-dimensional irreducible representations of the $S_rY(N)_p$ algebra are in one-to-one correspondence with the families $\{P_1(u), \ldots, P_{N-1}(u), \rho(u)\}$ where $P_i$ are monic polynomials of degree $m_i$ such that $\sum_i m_i \leq p$, and $\rho(u) = 1 + \sum_{n=0}^r d_n u^{-n}$.

In particular, in the case of the $W(sl(Np), N.sl(p))$ algebra, we obtain the result given in [1] for $N = 2$.

5.4 Center of $W_p(N)$ algebras.

From the definition of $W(gl(Np), N.sl(p))$ algebras, one already knows that their center contains the Casimir operators of $gl(Np)$, since, being central, these operators are obviously gauge invariant. Hence the dimension of the center is at least $Np$. However, it was not proved (to our knowledge) that its dimension is exactly $Np$. Fortunately, the center of the truncated Yangians $Y_p(N)$ has been determined in [5]:

**Property:** A basis of the $Y_p(N)$ center is given by all the coefficients of the principal part of the following generating function

$$H(x) = \sum_{w \in S_N} \sum_{i=1}^{N} \sum_{r_i=0}^{p-1} (-1)^{q(w)} T_{r_1}^{w(1)} T_{r_2}^{w(2)} \cdots T_{r_N}^{w(N)} \prod_{j=1}^{N} \left( \frac{(x - j)^{p-1-r_j}}{\prod_{k=1}^{p} (x - j - u_k)} \right)$$ (5.25)

where $S_N$ is the symmetric group and $T_{r_i}^{ab}$ are the Yangian generators.

Looking at the poles of $H(x)$, it is easy to see that there are exactly $Np$ poles (including multiplicities). A basis for this center (using quantum determinant) was also given in [14]. Hence, using this property and the above remark, we can deduce

**Corollary 5.5** The center of $W_p(N)$ is $Np$-dimensional and is given by $D_{Np}/I_p$. A basis of this center is canonically associated to the Casimir operators of $gl(Np)$.

Let us remark that the $p$ first Casimir operators can be chosen as elements of the $W_p(N)$ basis, while the next $p(N-1)$ ones are polynomials in the basis generators. Note that a different way to get these central generators has been given in [19]. It uses a determinant formula for $gl(Np)$ expressed for $J_{gf}$, namely:

$$\det(J_{gf} - \lambda I) = (-1)^{Np} \lambda^{Np} + \sum_{n=0}^{Np-1} C_{Np-n} \lambda^n$$ (5.26)
More generally, the same reasoning leads to the following center for $S_rY(N)_p$:

$$Z(S_rY(N)_p) = \mathcal{U}(d_{r+1}, \ldots, d_{pN})/T_p$$

(5.27)

It is generated by the last $(Np - r)$ independent Casimirs of $gl(Np)$.

6 Conclusion

We have shown that the finite $\mathcal{W}(gl(Np), N.sl)(p)$ algebras are nothing but truncated Yangians $Y(gl(N))_p$, i.e. coset of the Yangian $Y(gl(N))$ by the relations $T_{(n)}^{ab} = 0$ for $n \geq p$. The resulting coset is an algebra, but the Yangian Hopf structure does not survive to the quotient. This property enlightens the algebra homomorphism between Yangians and finite $\mathcal{W}$-algebras, and which was given in [1]. Using this property, we have been able to present these $\mathcal{W}$-algebras as exchange algebras, with the help of the Yangian R-matrix. This more abstract presentation is not linked to an Hamiltonian reduction, as were usually defined the $\mathcal{W}$-algebras. It could be of some help in the seek of a geometrical interpretation of $\mathcal{W}$-algebras. As a consequence, we have also given a complete classification of the finite dimensional irreducible representations for these $\mathcal{W}$-algebras. This classification completes the one given in [1] for $\mathcal{W}(sl(2n), 2.sl(n))$ algebras. Physically, one can hope to construct lattice models associated to $\mathcal{W}$-algebras, starting from models with Yangian symmetry.

Now that the relation between Yangians and $\mathcal{W}$-algebras is well-understood, one can hope to construct R-matrices for general $\mathcal{W}$-algebras: work is in progress in this direction. Conversely, one can think of generalizing the notion of Yangian as certain limits of $\mathcal{W}(G, H)$ algebras in which a (quasi) Hopf structure can be recovered. This would provide a wide class of new types of quantum groups.

Let us also remark that two other approaches for Yangians and $\mathcal{W}$-algebras could be related. On the one hand, one can construct Yangians as the projective limit of the centralizer of $gl(n)$ in $\mathcal{U}(gl(m + n))$ [24] (see also [25]), and on the other hand, some finite $\mathcal{W}$-algebras (of type $\mathcal{W}(gl(2n), n.sl(2))$) have been realized as commutants of a $gl(2n)$ parabolic subalgebra in a certain localization of $\mathcal{U}(gl(2n))$ [19]. It seems to us quite natural to look for a global description of these two point of view.

Of course, the case of conformal $\mathcal{W}$-algebras (i.e. extensions of the Virasoro algebra) has to be considered. It could be related to a multi-parametric generalization of Yangians. Would such a generalization be possible, one could think of an ”RTT presentation” of Virasoro algebra: this would allow to relate “usual” $\mathcal{W}$-algebras with the deformed $\mathcal{W}$-algebras presentation, a link which is not clear up to now, since two different deformed algebras can be constructed [26, 27]. Note finally that the construction of some conformal $\mathcal{W}$-algebras (such as the Virasoro and the $\mathcal{W}_3$ algebras) as commutant in a localization of an affine Kac-Moody algebra (see above paragraph) as been already achieve [13]: this could be a way to generalize the notion of Yangians, using the centralizer construction.
Acknowledgments

We warmly thank Daniel Arnaudon, Michel Bauer and Paul Sorba for fruitful and clarifying discussions and Alexander Molev for his enlightening comments about representations of Yangians.

A General settings on $gl(Np)$

We have gathered here the notations and properties we need about $gl(Np)$ algebra.

We consider the $gl(Np)$ algebra in its fundamental representation ($Np \times Np$ matrices), and take a basis adapted to the decomposition with respect to the $sl(2)$ algebra principal in $N.sl(p) \equiv sl(p) \oplus \ldots \oplus sl(p)$. This decomposition makes naturally appear the "factorization" $gl(Np) = gl(N) \otimes gl(p)$, valid in the fundamental representation, and the $sl(2)$ principal in $sl(p)$.

A.1 The principal embedding of $sl(2)$ in $sl(p)$

We will denote by $M_{j,m}$ (with $-j \leq m \leq j$ and $1 \leq j \leq p$) the $p \times p$ matrices resulting from the decomposition in $sl(2)$ multiplets:

\[
[e_+, M_{j,m}] = \frac{j(j+1) - m(m+1)}{2} M_{j,m+1} \quad (A.1)
\]

\[
[e_-, M_{j,m}] = M_{j,m-1} \quad (A.2)
\]

\[
[e_0, M_{j,m}] = m M_{j,m} \quad (A.3)
\]

\[
[e_0, e_\pm] = \pm e_\pm \quad \text{and} \quad [e_+, e_-] = e_0 \quad (A.4)
\]

where $e_{\pm,0}$ are the generators of the $sl(2)$ algebra principal in $sl(p)$. The normalizations in (A.1)-(A.2), although not symmetric, are adapted to the $\mathcal{W}$-algebra framework. When working with $gl(p)$ instead of $sl(p)$, we will add the $j = 0$ generator, proportional to the identity matrix.

The decomposition of $M_{j,m}$ in terms of the $p \times p$ matrices $E_{ab}$ reads

\[
M_{j,m} = \sum_{k=1}^{p-m} a_{j,m}^k E_{k,k+m} \quad \text{with} \quad a_{j,m}^k = \sum_{i=0}^{j-m} (-1)^{i+j+m} \binom{j-m}{i} a_{j,j}^{k-i} \quad (A.5)
\]

for $0 \leq m \leq j$

\[
M_{j,m} = \sum_{k=1}^{p+m} a_{j,m}^k E_{k,-m+k} \quad \text{with} \quad a_{j,m}^k = \sum_{i=0}^{j-m} (-1)^{i+j+m} \binom{j-m}{i} a_{j,j}^{k-i-m} \quad (A.6)
\]

for $-j \leq m \leq 0$
The generators $e_{\pm,0}$ of the $sl(2)$ algebra are proportional to the $M_{1,m}$ generators:

$$e_+ = \sum_{k=1}^{p-1} \frac{k(p-k)}{2} E_{k,k+1} = \frac{1}{2} M_{1,1}$$

$$e_0 = \sum_{k=1}^{p} \frac{(p+1-k)}{2} E_{k,k} = -\frac{1}{2} M_{1,0}$$

$$e_- = \sum_{k=1}^{p-1} E_{k+1,k} = -\frac{1}{2} M_{1,-1}$$

Let us remark that we have the following generating function for the coefficients $(p) a_{j,m}^k$ (where $(p)$ refers to the $gl(p)$ algebra under consideration):

$$(p) a_{j,m}^k = \left[ \frac{j!}{p! (k-1)! (j-m)!} \right] \left[ \frac{d^p d^j d^{j-m} d^{k-1}}{du^p dz^j dy^{j-m} dx^{k-1}} a(x, y, z, u) \right]_{x=y=0}$$

with

$$a(x, y, z, u) = \frac{u}{(1+y(1-x))(1-u[1+z+x(1-u)])}$$

The scalar product is given by

$$\eta_{j,m;\ell,n} = (M_{j,m}, M_{\ell,n}) = tr(M_{j,m} \cdot M_{\ell,n}) = (-1)^m \eta_j \delta_{j,\ell} \delta_{m+n,0}$$

with

$$\eta_j = (2j)! (j!)^2 \left( \frac{p+j}{2j+1} \right)$$

where the dot stands for the matrix product and $tr$ is the trace of matrices (in the $p$-dimensional representation).

In the following, we will need the Clebsch-Gordan like coefficients given by:

$$M_{j,m} \cdot M_{\ell,n} = \sum_{r=|j-\ell|}^{j+\ell} \sum_{s=-r}^r < j, m; \ell, n | r, s > M_{r,s}$$

As for usual Clebsch-Gordan coefficients, one can prove (using commutators by $e_{\pm,0}$) that $r$ must be in $[|j-\ell|, j+\ell]$ and that $s$ must be equal to $-m-n$. However, since we are in the fundamental of $sl(p)$, the coefficients will be truncated in such a way that only the values $r \leq p$ are kept in the decomposition (A.13). We will still call them Clebsch-Gordan coefficients.

Using the scalar product, one can compute these coefficients to be

$$< j, m; \ell, n | r, s > = \frac{(-1)^s}{\eta_r} tr(M_{j,m} \cdot M_{\ell,n} \cdot M_{r,0})$$
A.2 Few results about the Clebsch-Gordan like coefficients

Using the cyclicity of the trace, one shows

$$< j, m; \ell, n | r, s > = (-1)^{s+m} \frac{\eta_j}{\eta_r} < \ell, n; r, -s | j, -m >= (-1)^{s+n} \frac{\eta_\ell}{\eta_r} < r, -s; j, m | \ell, -n >$$  \hspace{1cm} (A.15)

We will also use the property

$$< j, m; \ell, n | r, s > = \frac{(j-m)!(\ell-n)!(r+s)!}{(j+m)!(\ell+n)!(r-s)!} < \ell, -n; j, -m | r, s >$$  \hspace{1cm} (A.16)

where the coefficients are due to the non-symmetric basis we have chosen.

With these two properties, one can compute:

$$< r, -r; k, k | j, -j > = (-1)^k \frac{\eta_{j+k}}{\eta_j} \delta_{r,j+k}$$  \hspace{1cm} (A.17)

$$< k, k; r, -r | j, -j > = (-1)^k \frac{\eta_{j+k}}{\eta_j} \delta_{r,j+k}$$  \hspace{1cm} (A.18)

$$< r, 1-r; k, k | j, 1-j > = (-1)^k \frac{j \eta_{j+k}}{j+k \eta_j} \delta_{r,j+k}$$  \hspace{1cm} (A.19)

$$< k, k; r, 1-r | j, 1-j > = (-1)^k \frac{j \eta_{j+k}}{j+k \eta_j} \delta_{r,j+k}$$  \hspace{1cm} (A.20)

$$< r, -r; k, k | j, 1-r > = (-1)^{k+1} \frac{k j \eta_{j+k-1}}{\eta_j} \delta_{r+1,j+k}$$  \hspace{1cm} (A.21)

$$< k, k; r, -r | j, 1-r > = (-1)^k \frac{k j \eta_{j+k-1}}{\eta_j} \delta_{r+1,j+k}$$  \hspace{1cm} (A.22)

We will also need the following coefficients:

$$< k, k; 1-k, 1 | k, 1 > = (-1)^{k+1} \frac{\eta_k}{\eta_1} \equiv c_k$$  \hspace{1cm} (A.23)

$$< k, 1-k; k, 1 | k, 1 > = -c_k$$  \hspace{1cm} (A.24)

$$< k, k; k-1, 1-k | 1, 1 > = \frac{1}{k(2k-1)} c_k$$  \hspace{1cm} (A.25)

$$< k-1, 1-k; k, 1 | k, 1 > = \frac{1}{k(2k-1)} c_k$$  \hspace{1cm} (A.26)

$$< k+1, 1-k; k, 1 | k, 1 > = -\frac{(k+1)(p^2-(k+1)^2)}{2k+3} c_k$$  \hspace{1cm} (A.27)

$$< k, k; k+1, 1-k | 1, 1 > = -\frac{(k+1)(p^2-(k+1)^2)}{2k+3} c_k$$  \hspace{1cm} (A.28)
A.3 Basis for $gl(Np)$

We can use the above basis of $gl(p)$ to construct a basis for $gl(Np)$. Using the $N \times N$ matrices $E_{ab}$, the generators $\Upsilon_{ab}^m$ of $gl(Np)$ in the fundamental will be represented by

$$\pi_F(\Upsilon_{ab}^m) = M_{ab}^m = E_{ab} \otimes M^m$$

(A.29)

The generators of the $sl(2)$ algebra principal in $N.sl(p)$ are then

$$\epsilon_{\pm,0} = 1_N \otimes \epsilon_{\pm,0}$$

(A.30)

where $\epsilon_{\pm,0}$ are the $p \times p$ matrices defined above. We have the following commutation relations

$$[\epsilon_+, M_{ab}^j] = \frac{1}{2}(j(j + 1) - m(m + 1))M_{ab}^{j,m+1}$$

(A.31)

$$[\epsilon_-, M_{ab}^j] = M_{ab}^{j,m-1}$$

(A.32)

$$[\epsilon_0, M_{ab}^j] = mM_{ab}^{j,m}$$

(A.33)

$$[\epsilon_0, \epsilon_{\pm}] = \pm \epsilon_{\pm} \quad \text{and} \quad [\epsilon_+, \epsilon_-] = \epsilon_0$$

(A.34)

together with

$$[M_{ab}^{00}, M_{cd}^{00}] = \delta_{bc}M_{ad}^{00} - \delta_{ad}M_{cb}^{00}$$

(A.35)

This last commutator reveals the $gl(N)$ algebra which commutes with the $sl(2)$ subalgebra under consideration.

More generally, the product law (in the fundamental representation) reads

$$M_{ab}^{j,m} \cdot M_{cd}^{\ell,n} = \delta_{bc} \sum_{r=|j-\ell|}^{j+\ell} \sum_{s=-r}^{r} <j, m; \ell, n| r, s > M_{ad}^{r,s}$$

(A.36)

which leads to the following commutation relations (valid in the abstract algebra):

$$[\Upsilon_{ab}^m, \Upsilon_{cd}^n] = \sum_{r=|j-\ell|}^{j+\ell} \sum_{s=-r}^{r} \left( \delta_{bc} <j, m; \ell, n| r, s > \Upsilon_{ad}^{r,s} - \delta_{ad} <\ell, n; j, m| r, s > \Upsilon_{cb}^{r,s} \right)$$

(A.37)

The scalar product is

$$\eta_{ab,cd}^{j,m;\ell,n} = (\Upsilon_{ab}^m, \Upsilon_{cd}^n) = tr(M_{ab}^{j,m} \cdot M_{cd}^{p,n}) = \delta_{a,d} \delta_{b,c} \eta_{ab,cd}^{j,m;\ell,n}$$

(A.38)

B Deformations and cohomology

We include here some definitions (in the context of Chevalley cohomology) to be self-content. For more details about deformations and their relation to cohomology, we refer to [28] and ref. therein.
B.1 Few words about Chevalley cohomology

We begin with an algebra $\mathcal{A}$, and first introduce the space $C^n(\mathcal{A}, \mathcal{A})$ of $n$-cochains with values in $\mathcal{A}$, i.e. skew-symmetric linear maps from $\land^n \mathcal{A}$ to $\mathcal{A}$. The Chevalley derivation $\delta$ maps $n$-cochains to $(n+1)$-cochains as:

$$(\delta \chi_n)(u_0, \ldots, u_n) = \sum_{i=0}^{n} (-1)^i \{ u_i, \chi_n(u_0, u_1, \ldots, \hat{u}_i, \ldots, u_n) \} + \sum_{0 \leq i < j \leq n} (-1)^{i+j} \chi_n(\{u_i, u_j\}, u_0, u_1, \ldots, \hat{u}_i, \ldots, \hat{u}_j, \ldots, u_n)$$

where, as usual, $\hat{u}_i$ means that $u_i$ has to be discarded in the list (or product, or sum, or whatever) we consider.

It can be shown that $\delta$ squares to zero:

$$(\delta(\delta \chi_n))(u_{-1}, u_0, u_1, \ldots, u_n) = 0 \quad \forall u_{-1}, u_0, u_1, \ldots, u_n ; \forall \chi_n ; \forall n \quad (B.39)$$

Thus, we introduce the cohomology associated to $\delta$, i.e. we focus on $\text{Ker}\delta$. Elements of $\text{Ker}\delta$ are called cocycles, and we will see that they play a direct role in the deformation of Lie algebras. The space of $n$-cochains (with values in $\mathcal{A}$) is denoted $Z_n(\mathcal{A}, \mathcal{A})$:

$$\text{Ker}\delta = \bigoplus_n Z_n(\mathcal{A}, \mathcal{A})$$

Since $\delta^2 = 0$, we have $\text{Im}\delta \subset \text{Ker}\delta$: each $n$-cochain provides a $(n+1)$-cocycle. The elements $\delta \chi_n$ correspond to “trivial” cocycles: they are called coboundaries, and the corresponding space denoted $B_n(\mathcal{A}, \mathcal{A})$. The cohomology describes the non-trivial cocycles, i.e. it is the space $H_n(\mathcal{A}, \mathcal{A}) = Z_n(\mathcal{A}, \mathcal{A})/B_n(\mathcal{A}, \mathcal{A})$, $H(\mathcal{A}, \mathcal{A}) = \bigoplus_n H_n(\mathcal{A}, \mathcal{A}) = \text{Ker}\delta/\text{Im}\delta$. Due to its definition, the Chevalley cohomology is naturally associated to Lie algebras. When the cochains take values in $\mathbb{C}$ instead of $\mathcal{A}$, the space $H_2(\mathcal{A}, \mathbb{C})$ classifies the non-trivial central extensions of $\mathcal{A}$: see for instance $[29]$ where central extensions of generalized loop algebras are classified and computed. In the case we are considering, $C(\mathcal{A}, \mathcal{A})$ is related to deformations of $\mathcal{A}$.

B.2 Deformations

We start again with an algebra, with generators $u_\alpha$ ($\alpha \in \Gamma$).

$$\{ u_\alpha, u_\beta \} = f^{\alpha\beta}{}_{\gamma} u_\gamma$$

Actually, we will consider its enveloping algebra $\mathcal{A}$, and introduce a deformation of it

$$\{ u_\alpha, u_\beta \}_h = f^{\alpha\beta}{}_{\gamma} u_\gamma + \sum_{n=1}^{\infty} h^n \varphi_n(u_\alpha, u_\beta)$$

where the antisymmetric bilinear forms $\varphi_n$ take values in $\mathcal{A}$: they are all elements of $C_2(\mathcal{A}, \mathcal{A})$. 

28
Asking the bracket \( \{\cdot,\cdot\}_\hbar \) to obey the Jacobi identity leads to the following equations:

\[
\begin{align*}
\delta \varphi_1 & = 0 \\
\delta \varphi_n & = \sum_{j+k=n} \left( \varphi_j(\varphi_k(u,v),w) + \varphi_j(\varphi_k(v,w),u) + \varphi_j(\varphi_k(w,u),v) \right) \quad \text{for } n > 1
\end{align*}
\]

where the operation \( \delta \) defined in section [B.1] has naturally appeared.

These equations indicate that \( \varphi_1 \) is a cocycle, while \( \varphi_n \) is determined by the \( \varphi_p \)'s (\( p < n \)) up to a cocycle. Note that \( \delta \varphi_n \) is a coboundary, so that the \( \varphi_p \), \( p < n \), must be such that the r.h.s. of \([B.41]\) is also a coboundary (it can be proven that this r.h.s. is indeed a cocycle, i.e. is annihilated by \( \delta \)). If the third cohomological space is not trivial, the r.h.s. of \([B.41]\) may be a cocycle while being not a coboundary: this leads to the usual assumption that the third cohomological space classify the obstructions to deformations. In other words, it could appear that, in the attempt to construct a deformation, the chosen \( \varphi_p, p < n \) are such that the l.h.s. of \([B.41]\) is a non-trivial cocycle, so that one cannot solve this equation at level \( n \). In that case, the deformation would be ill-defined.

Fortunately, in the case we will consider below, we already know that we have well-defined deformations, and we have not to deal with a possible obstruction.

Note also that if \( \varphi_n \) is a coboundary

\[
\varphi_n(u_\alpha, u_\beta) = \delta \chi_n(u_\alpha, u_\beta) = \{u_\alpha, \chi_n(u_\beta)\} - \{u_\beta, \chi_n(u_\alpha)\} - \chi_n(\{u_\alpha, u_\beta\})
\]

we can perform a change of basis

\[
\tilde{u}_\alpha = u_\alpha - \hbar^n \chi_n(u_\alpha)
\]

such that in this new basis, the term in \( \hbar^n \) has disappeared:

\[
\{\tilde{u}_\alpha, \tilde{u}_\beta\}_\hbar = f^{\alpha\beta}_\gamma \tilde{u}_\gamma + \sum_{m=1}^{n-1} \hbar^m \tilde{\varphi}_m(\tilde{u}_\alpha, \tilde{u}_\beta) + \sum_{m=n+1}^{\infty} \hbar^m \tilde{\varphi}_m(\tilde{u}_\alpha, \tilde{u}_\beta)
\]

where \( \tilde{\varphi}_m, m > n \) are new cochains resulting from the change of variables. In that sense, a coboundary leads to a trivial deformation. However, one has to be careful that to "trivialize" the full deformation, the change of basis has to be done recursively and the coboundarity at level \( n \) has to be checked once the change of basis at level \( n - 1 \) has been done (since the cochains are modified at higher order).
