INTRODUCTION

Bladder outlet obstruction (BOO) is a common cause of lower urinary tract symptoms (LUTS) in elderly men over 50 yr of age (1). BOO results from various etiologic factors that may have functional and anatomical components (2). Because of the complex etiological aspects, the issue of how to accurately evaluate BOO in men with LUTS has been debated for decades (3-5). Thus, when considering management of men with LUTS suggestive of BOO, it is important to take into account the specific aspects of BOO.

Currently, pressure-flow studies (PFS) are widely accepted as the gold standard diagnostic method for identifying BOO (5). Even though PFS is essential for the evaluation of BOO before invasive treatment is considered, many clinicians do not perform PFS as they consider it is invasive, time-consuming and expensive (6). In clinical practice, most often non-invasive methods are used to evaluate men with LUTS such as the maximal flow rate, postvoid residual volume, prostate size, and International Prostate Symptom Score (I-PSS). International guidelines suggest that mandatory and recommend-
International Prostatic Symptom Score.

Non-invasive Parameters Predicting Bladder Outlet Obstruction 273

We compared these two groups with respect to age, maximal flow rate ($Q_{\text{max}}$), voided volume, postvoid residual volume, serum PSA level, prostate volume, I-PSS, and the urodynamic variables. The Statistical Package for the Social Sciences, version 12.0 (SPSS Inc., Chicago, IL, USA) was used for the statistical analysis. The patient characteristics were analyzed by the Student’s t-test and chi-square test. Univariate analysis was conducted using the chi-square test and linear regression analysis. The multivariate analysis was performed with the bivariate logistic regression. $P<0.05$ was accepted as statistically significant.

**RESULTS**

The characteristics of each patient group are shown in Table 1. Patients with BOO had a lower $Q_{\text{max}}$ (7.34 ± 3.12 vs. 11.49 ± 5.24) ($P<0.05$) and lower voided volume. Also patients with BOO had a higher serum PSA level (3.45 ± 4.12 vs. 2.45 ± 3.42) ($P<0.05$) and a larger prostate volume (50.95 ± 28.16 vs. 41.63 ± 21.64) ($P<0.05$). For the urodynamic parameters, patients with BOO had a significantly higher rate of involuntary detrusor contraction (34.3%, 47/137 vs. 24.3%, 71/292) and poor compliance (19.1%, 26/137 vs. 6.3%, 18/292) compared to the patients without BOO. However, no significant differences were found for age, postvoid residual volume, maximal cystometric capacity, and symptom scores between the two groups ($P>0.05$, Table 1).

The univariate analysis showed that several parameters had significant predictive value for BOO (Table 2); an older age,

### Table 1. Comparison of clinical parameters between patients with bladder outlet obstruction (BOO) and without BOO

| Parameters                              | Bladder outlet obstruction | $P$ value |
|-----------------------------------------|----------------------------|-----------|
| Age (yr)                                | Present (n=137)            | Absent (n=292) |          |
| Q$_{\text{max}}$ (mL/sec)               | 69.90 ± 7.67              | 67.08 ± 7.60 | 0.412    |
| Voided volume (mL)                      | 199.47 ± 116.39           | 288.23 ± 137.75 | 0.122    |
| Postvoid residual volume (mL)           | 139.42 ± 110.90           | 105.01 ± 120.40 | 0.92*    |
| Maximal cystometric capacity (mL)       | 346.57 ± 110.52           | 386.29 ± 106.10 | 0.256*   |
| Involuntary detrusor contraction (%)    | 47 (34.3)                 | 71 (24.3)    | 0.037*   |
| Poor compliance (%)                     | 26 (19.1)                 | 18 (6.3)     | 0.001*   |
| BOOI                                    | 63.87 ± 26.91             | 19.01 ± 14.67 | 0.001*   |
| Prostate specific antigen (ng/dL)       | 3.45 ± 4.12               | 2.45 ± 3.42  | 0.047*   |
| Total prostate volume (mL)              | 50.95 ± 28.16             | 41.63 ± 21.64 | 0.033*   |
| Transition zone volume of prostate (mL) | 25.42 ± 22.72             | 18.53 ± 16.62 | 0.002*   |
| IPSS (sum)                              | 19.32 ± 8.80              | 19.82 ± 8.07 | 0.089*   |
| Voiding symptom                         | 10.97 ± 5.81              | 11.79 ± 5.57 | 0.516*   |
| Storage symptom                         | 8.31 ± 3.91               | 8.09 ± 3.71  | 0.225*   |
| Quality of life                          | 4.07 ± 1.34               | 4.22 ± 1.42  | 0.678*   |

*Student’s t-test; *Chi-square test were used for data analysis.

### Table 2. Univariate analysis of predicting factors for bladder outlet obstruction (BOO) with using chi-square test

| Parameters                              | BOO rate (%) | $P$ value |
|-----------------------------------------|--------------|-----------|
| Age (yr)                                |              | 0.003     |
| 50-59                                   | 51.8         |           |
| 60-69                                   | 6.3%         | 26.3      |

increase in the rate of obstruction and a decrease of the $Q_{\text{max}}$. Patients with BOO had a higher rate of significant postvoid residual volume (more than 100 mL) and serum PSA level (more than 4 ng/dL). The multivariate analysis showed that only $Q_{\text{max}}$ and poor compliance were significant predictive factors for BOO (Table 3).

**DISCUSSION**

The results of this study showed that male LUTS patients with BOO had a higher serum PSA level and a larger prostate volume than those without BOO. Although other investigations reported that prostate volume and serum PSA level were poorly correlated with BOO (15, 16), our results suggest that BOO was associated with prostate size and serum PSA level; these factors may indicate progression of benign prostatic hyperplasia. However, no significant differences were found for age, postvoid residual volume, maximal cystometric capacity, and symptom scores between the men with BOO and those without BOO. In addition, only two parameters, the $Q_{\text{max}}$ and poor compliance, were significant independent predictive factors for BOO by the multivariate analysis. Sonke et al. (17) demonstrated that frequently used diagnostic parameters such as prostate volume, postvoid residual volume and I-PSS were not useful for the prediction of BOO, and the correlation between these parameters and the PFS findings was poor. Vesely et al. (2) reported similar findings; no correlation was noted for the degree of obstruction and the differences in these parameters, in addition to the $Q_{\text{max}}$. They reported that the simple, non-invasive diagnostic methods were not accurate for the diagnosis of BOO.

On the other hand, Steele et al. (18) showed that combining the symptom scores, maximal flow rate, and prostate volume were useful non-invasive parameters for predicting BOO, although these parameters had poor predictive power when used alone. Tanaka et al. (19) also demonstrated that men with LUTS and BOO can be identified by the prostate volume, $Q_{\text{max}}$, postvoid residual volume, and I-PSS with a 90% positive predictive value. Thus, the ability of these variables to predict BOO remains controversial.

Recently, other factors used to predict BOO have been reported and include intravesical prostatic protrusion, prostatic urethral angle, and the detrusor wall thickness. Nose et al. (20) suggested that the sensitivity of intravesical prostatic protrusion grade increased in direct proportion to the grade of obstruction; they confirmed that the IPP grading system was useful for the diagnosis of BOO. Oelke et al. (6) conducted a prospective study to find non-invasive tests for the evaluation of BOO; they suggested ultrasound measurements of detrusor wall thickness was better than the $Q_{\text{max}}$, postvoid residual volume or prostate volume for the diagnosis of BOO. Cho et al. (21) also showed that prostatic urethral angle was an important factor associated with BOO in patients with LUTS; they reported that patients without anatomical obstruction could be successfully treated with a transurethral incision of the bladder neck, which resulted in the resolution of bladder neck elevation. However, these novel methods require further confirmation.

Although not a few urologists treat patients with LUTS suggestive of BOO based on the suspicion of anatomic obstruction due to prostate enlargement, BOO is considered to be often combined with functional factors such as secondary bladder dysfunction (22, 23). If men with LUTS have BOO combined with an overactive bladder, resolution of the obstruction by reduction of the prostate size may not cure the patient’s symptom. Consistent with this concept, the present study showed that secondary bladder function changes, such as detrusor overactivity or poor compliance, were more common in patients with BOO. Several investigations have shown that secondary bladder dysfunction was independently associated with BOO (24, 25). The hypothetical explanations for BOO induced bladder dysfunction have been illustrated in animal and human models (26-28). According to prior experimental results, BOO induces marked remodeling of the bladder wall, which includes cellular hypertrophy, hyperplasia and reorganization of the relative structural relationship between connective tissue and smooth muscle elements (26, 27). As the duration of BOO increases, bladder function may decompensate, characterized by functional instability such as an overactive bladder, poor compliance, increasing postvoid residual volume, and decreased contractility (28). Thus, a combination of pathophysiological factors must be considered when treating men with BOO. Based on the results of present study, we suggest BOO must be treated in males with LUTS as BOO subsequently induces deleterious bladder change. And we are planning to perform further study to investigate the impact of BOO on bladder function.

In conclusion, even though several non-invasive methods used for the evaluation of BOO, only maximal flow rate plays

---

**Table 3. Multivariate logistic regression of predicting factors for bladder outlet obstruction**

| Variables                           | $P$ value | Adjusted odds ratio | 95% confidence interval |
|-------------------------------------|-----------|---------------------|-------------------------|
| Maximal flow rate (mL/sec)          | 0.001     | 0.78                | 0.711 - 0.857           |
| Voided volume (mL)                  | 0.636     | 1.01                | 0.997 - 1.005           |
| Involuntary detrusor contraction     | 0.539     | 0.82                | 0.452 - 1.515           |
| Poor compliance                     | 0.039     | 0.45                | 0.213 - 0.965           |
| Serum prostate specific antigen (PSA) (ng/dL) | 0.243 | 1.05                | 0.968 - 1.138           |
| Total prostate volume (mL)          | 0.077     | 1.02                | 0.997 - 1.054           |
| Transition zone volume of prostate (mL) | 0.326 | 0.98                | 0.947 - 0.947           |
a significant role in predicting of BOO in Korean men with LUTS. Thus, abnormal finding of uroflowmetry indicates the need for performing PFS. In addition, BOO is significantly associated with detrusor dysfunction, therefore, secondary bladder dysfunction must be emphasized in the management of male patients with LUTS suggestive of BOO.
