Abstract

Nitrogen in manure occurs mainly in organic forms (e.g., proteins) and as ammonium (NH4+). Some composted manures contain small amounts of nitrate. Ammonium and nitrate are plant-available forms of N, while organic N is not immediately plant-available. Before organic N can be taken up, however, it must first be converted to inorganic forms. This process, which is completed by soil microbes as a by-product of organic matter decomposition, is called mineralization. The mineralization rate is therefore the rate at which organic N is made plant available. In manure forage systems, mineralization accounts for much or most of crop needs. To calculate the N fertilizer value of manure and to construct crop N budgets, an estimate of the rate of mineralization is useful. An understanding of the mineralization rate concept can help improve manure management to meet crop N demands. However, proper management of organic manures requires a capacity to predict their effect of N dynamics in inceptisol and their availability to crops. The quality of organic material is reflected in the carbon (C), nitrogen (N) and C/N ratio. Generally, manures with low C/N ratio (lesser than 10:1) result in greater N availability at the early stage of decomposition. Therefore it gives real benefits of applying these organic materials to soil.

Introduction

In recent past, there is a renewal interest on the use of organic resources in agricultural for maintaining soil organic matter, improving soil quality and supplying plant nutrient for sustainable crop production. The use of organic waste in the amendment of agricultural soils can be beneficial for crops, and the same time, provide an efficient and cost effective method for its disposal. The organic fraction of manure can significantly increase soil aggregation, infiltration, microbial activity, structure, and water-holding capacity and can reduce soil compaction and erosion. Therefore, it gives real benefits of applying these organic materials to soil. The determination of N mineralization potential in soil after organic amendments allows the evaluation of N dynamics in the soil and its true effectiveness in economic and ecological effect (Pedra et al., 2011).

The incorporation of organic manures into soil is considered a good management practices because it stimulates soil microbial activity and increases soil fertility through mineralization. Inceptisol are in medium range of organic matter which is the backbone for the sustainability of soil fertility and
productivity. An improved understanding of the competing processes of N mineralization and N immobilization, along with their temporal dynamics, may improve our ability to manage N cycling, increase Nitrogen use efficiency (NUE) by minimizing N losses whatever the form, and increase the sustainability of agricultural systems that utilize typically applied organic N sources (Cabrera et al., 2005).

Stanford and Smith (1972) were establishing the N mineralization capacity through long term incubation procedures. Kinetics parameters in mineralization study can be potentially used to access the mineralization-immobilization process in soils under varying environmental and management conditions. Nitrogen-use efficiency can be enhanced through the understanding of N-mineralization potential of different organic sources. The aim of present study was to determine and compare N mineralization rate, under laboratory condition amended with different organic residues in Inceptisol. The suitability of organic residues as a source of N depends to great extent on its mineralization of N in relation to crop demand.

Materials and Methods

The eight value added organic manures in 1 kg Inceptisol of Typic Haplustept family air dried 2 mm sieve soil were used for conducting experiment in plastic bowl with capacity of 1.5 kg at field capacity moisture regimes (0.33 bar), maintained by double distillery water throughout the incubation period in three replications under Completely Randomized Design. The organic manures sources were applied at the rate of 100 mg N kg⁻¹ soil (Table 1) and treatment details are following:

| T  | Organic Manure               | Source                                      |

Physico-chemical and Chemical properties of soil

Soil moisture at field capacity determined by Pressure plate membrane apparatus method (Richards, 1949), pH (1:2.5, Soil: water) Potentiometry and EC (1:2.5, Soil:water) Conductometry method, Organic carbon by Wet oxidation as explain by Jackson, 1973), Calcium carbonate by Acid neutralization (Allison and Moodie, 1965), Available N Alkaline permanganate (Subbiah and Asija, 1956), Available phosphorus 0.5M NaHCO₃ at pH 8.5 ascorbic acid (Watanabe and Olsen, 1965), Available potassium by Neutral Normal NH₄OAc (Knudsen et al., 1982), Micronutrient( Mn, Fe, Cu, Zn ) by DTPA extractable method (Lindsay and Norvell, 1978) and NH₄-N and NO₃ –N determined with 2M KCl solution (1:10 sample: extrant ratio) by steam distillation in presence of MgO and Devardas alloy method respectively as explain by Keeney and Nelson (1982). The 5 g soil from each bowl was weighted for analysis of NH₄-N and NO₃-N at 15 days interval up to 90 days.

Organic manure analysis

The well decomposed organic manures samples were air dried under shed and adopting appropriate standard methods such as Potentiometric for pH and Conductometry for EC(1:10 compost : water) as explain by Jackson (1973).Total nitrogen by Microkjeldahl method (Bremner and Mulvaney, 1982), Total phosphorus by Vandomolybdo -phosphate Yellow colour (Jackson, 1973), Total potassium by Flame photometer (Chapman and Pratt, 1961) while Organic carbon by Ignition method Gorsuch (1970).

Result and Discussions

Characterization of organic manure

The pH of different organic manures ranged from 5.0 to 8.6 with mean value of 7.47, FYM recorded higher pH (8.6) while lower pH (5.0) in coco-pit compost. Electrical conductivity of poultry manure (6.31 dS m⁻¹) was higher and lowest in press mud compost (1.25 dS m⁻¹). The concentration of carbon in organic manures
differed considerably ranging from 20.61% in spent mushroom compost to 33.94% in poultry manure with mean value (26.80 %). The N concentration in organic manures ranged from 0.71 % in coco-pit compost to 3.09 % in poultry manure. The concentration of total P in organic manures differed considerably ranging from 0.35% in coco-pit compost to 1.98 % in press mud compost. Variation in total K concentration among the organic manures was small ranging from 0.33% in coco-pit compost to 0.94 in spent mushroom compost with mean value (0.60 %).

It was evident from the data following decreasing trend was obtained:
N concentration: poultry manure > urban compost > vermicompost > press mud compost > FYM > spent mushroom compost > press mud cake > coco-pit compost.
C/N ratio: coco-pit compost > press mud cake > FYM > urban compost > vermicompost > poultry manure.
C/P ratio: coco-pit compost > poultry manure > urban compost > FYM > spent mushroom compost > vermicompost > press mud cake > coco-pit compost.

Nitrogen mineralization

The F.Y.M, vermicompost, press mud cake, press mud compost, poultry manures, coco-pit compost, urban compost and spent mushroom compost were incorporated in soil @ 100 mg of N kg-1 soil and incubated for total 90 days at field capacity moisture. The mineralization of N into NH4-N and NO3-N at different intervals was studied.

Ammoniacal nitrogen (NH4- N)
The soil amended with organic manures released significantly higher amount of NH4-N than that of soil alone. Amongst organic manures, poultry manure recorded highest amount of cumulative NH4-N (223.24 mg kg-1) this could be due to higher N content and narrower C/N ratio. The next best treatment was urban compost followed by vermicompost. It was lowest in control (126.76 mg kg-1). The result indicated that the combined application of organic manures released higher amount of N than soil alone. This could be attributed to the rate of decomposition and amount of N mineralized varies with type of organic material added (Gupta and Tripathi, 1986).

The NH4-N release pattern from organic manures amended soil also recorded identical trend but magnitude of rate of mineralization followed the order; poultry manure > urban compost > vermicompost > press mud compost > FYM > spent mushroom compost > press mud cake > coco-pit compost > control.

Nitrate nitrogen (NO3- N)
The soil amended with organic manures released significantly higher amount of NO3- N than that amended with soil alone throughout incubation period. The rate of release NO3- N was slow in the beginning and released with a peak appearing at 45 days aerobic incubation.

There after NO3- N release decreased gradually beyond 45 days in all the soil amended with organic manure treatments. Generally poultry manure > urban compost >vermicompost> press mud compost > FYM > spent mushroom compost >press mud cake > coco-pit compost > control was the decreasing order of organic manures on the basis of NO3- N values during mineralization. The cumulative NO3-N was more due to poultry manure (396.67 mg kg-1), urban compost (370.18 mg kg-1) and vermicompost (353.15 mg kg-1) respectively. This could be due to higher N content and narrower C/N ratio of poultry manure, urban compost and vermicompost respectively. It was lowest in control (208.11 mg kg-1). This result indicated that the combined application of organic manures released higher amount of NO3-N than control or soil alone. This could be attributed to application of manures which on mineralization release inorganic N steadily.

Nitrogen mineralization (NH4-N+NO3-N)
The N mineralization values ranges between 90.18 and 126.13 mg kg -1at 0 and 45 days incubation thereafter it was declined at 90 days incubation (46.04 mg kg-1) in poultry manure while lowest was noticed in unamend soil or control and range was 40.36-73.15 mg kg-1 at 45 days incubation and 22.07 mg kg-1 at 90 days incubation. Amongst the organic manures poultry manure recorded highest rate of N mineralization (619.91 mg kg-1) the next best was urban compost (553.06 mg kg-1) followed by vermicompost (528.47 mg kg-1). This could be
due to higher N content and narrower C/N ratio of poultry manure, urban compost and vermicompost respectively. The ability of eight organic manures to release N was in the following order; poultry manure > urban compost >vermicompost> press mud compost > FYM > spent mushroom compost > press mud cake > cocom-pit compost. The lowest rate of N mineralization in cocom-pit compost may be attributed to low N content and wider C/ N ratio was compared to the rest of organic manures. In general to summarize all the organic manures had almost reached the potential N mineralization incubation period 30 to 45 days indicating that organic manures may release N rapidly and provide sufficient N during amount of N mineralized by organic manures amended soil indicated that Total N content and C/N ratio of organic manures were extremely important in predicting the amount of N mineralized.

The present study was conducted with view to evaluate the Characterization of organic manure, kinetics of N mineralization by using organic manures in Inceptisol and to find out the best fit mathematical model for assessing nitrogen mineralization in Inceptisol. The salient findings of investigation are summarized below:

The pH of ranged from 5.0 in cocom-pit compost to 8.6 in FYM, EC 1.25 dS m⁻¹ in press mud compost to 6.31 dS m⁻¹ in poultry manure. The carbon in concentration in organic manure ranged from 20.61 per cent in spent mushroom compost to 33.94 per cent in poultry manure with mean value (26.80 %). The N concentration in organic manure ranged from 0.71 per cent in cocom-pit compost to 3.09 per cent in poultry manure, P concentration 0.35 per cent in cocom-pit compost to 1.98 per cent in press mud compost, K concentration 0.33 per cent in cocom-pit compost to 0.94 per cent in spent mushroom compost. There was wide variation in C/N and C/P ratio of organic manures ratios. The C/N ratio of organic manure varied inversely to their N concentration.

The NH₄-N release pattern from organic manures amended soil also recorded identical increasing trend up to 45 days and thereafter decreasing trend was noticed. However, magnitude of rate of mineralization followed in the order: poultry manure > urban compost >vermicompost >press mud compost > FYM > spent mushroom compost > press mud cake > cocom-pit compost. The lowest cumulative release of NH₄-N (142.54 mg N Kg⁻¹) was noticed in cocom-pit compost. The highest cumulative release of NH₄-N (223.24 mg N Kg⁻¹) was observed in poultry manure. The rate of release of NH₄-N was slow in the beginning and followed by sharp increase reaching, a peak at 45 days of incubation followed by gradual decline thereafter in all the organic manures amended treatments.

The poultry manure (396.67 mg kg⁻¹), urban compost (370.18 mg kg⁻¹) and vermicompost (353.15 mg kg⁻¹) observed the more cumulative NO₃-N as compared with rest of the treatments. The soil amended with organic manures released significantly higher amount of NO₃- N than control treatment throughout the incubation period. The maximum, amount of NO₃- N release was noticed at 45 days after incubation in all the sources of organic manures and control treatment. The decreasing order of release of nitrate nitrogen is poultry manure > urban compost > vermicompost > press mud compost > FYM > spent mushroom compost > press mud cake > cocom-pit compost. Among the source the cocom-pit recorded the lowest release of soil NO₃- N throughout the incubation period but it was higher than control treatment.

Significantly the highest mineralized NH₄-N + NO₃-N was observed due to the application of poultry manure over all the sources of organic manure and control treatments throughout the incubation period. In general, the use of all the sources of organic manure significantly increased the release of NH₄-N + NO₃-N as compared with control. The highest peak rate of N was attained at 45 days of incubation in all the treatments. Thereafter it gradually declined significantly at 90 days of incubation period. The application of poultry manure resulted in higher release rate of NH₄-N + NO₃-N mineralization throughout incubation period. Amongst the organic manures poultry manure recorded the highest rate of N mineralization (619.914mg kg⁻¹) the next best was urban compost (553.06 mg kg⁻¹) followed by vermicompost (547.28 mg kg⁻¹). In general, all the organic manures reached the potential N mineralization incubation period 35 to 45 days.
