CONTINUITY OF THE SRB ENTROPY OF CONVEX PROJECTIVE STRUCTURES

PATRICK FOULON AND INKANG KIM

Abstract. The space of convex projective structures has been well studied with respect to the topological entropy. But, to better understand the geometry of the structure, we study the entropy of the Sinai-Ruelle-Bowen measure and show that it is a continuous function.

in memoriam Rufus Bowen

1. Introduction

A topological manifold $M$ can be equipped with a $(G,X)$-structure where $X$ is a model space and $G$ is a group acting on $X$, so that $M$ has an atlas $\{(\phi_i,U_i)\}$ from open sets $\{U_i\}$ in $M$ into open sets in $X$ and the transition maps $\{\phi_i \circ \phi_j^{-1}\}$ are restrictions of elements in $G$. Depending on the choice of $(G,X)$, many interesting geometric structures can arise. For instance, if $M$ is a closed surface with genus at least 2, a hyperbolic structure corresponds to $(\text{PSL}(2,\mathbb{R}),\mathbb{H}^2)$, a real projective structure to $(\text{PGL}(3,\mathbb{R}),\mathbb{R}\mathbb{P}^2)$, and a complex projective structure to $(\text{PSL}(2,\mathbb{C}),\mathbb{C}\mathbb{P}^1)$.

Given a geometric structure, there exist a developing map $D: \tilde{M} \to X$ which is a local homeomorphism and a holonomy representation $\rho: \pi_1(M) \to G$, so that $D$ is $\rho$-equivariant. In this paper, we study the real projective structures $(\text{PGL}(n+1,\mathbb{R}),\mathbb{R}\mathbb{P}^n)$, and especially the strictly convex real projective structures $\mathcal{P}_n(M)$ on a closed manifold $M$, that is when $\Omega = D(\tilde{M})$ is a strictly convex open domain of $\mathbb{R}\mathbb{P}^n$.

The set $\mathcal{P}_n(M)$ of equivalence classes of such strictly convex real projective structures, in the case of a closed surface, is known as Hitchin component in a character variety $[13,23]$. It has drawn much attention recently and many aspects of the set have been studied. The space
has been identified as the holomorphic vector bundle over Teichmüller space \([4, 11, 12, 26, 30]\) using affine sphere theory. It is also identified with the space of Anosov representations \([27]\). Explicit coordinates are studied \([7, 8, 19, 22]\) and the space has a mapping class group invariant Kähler metric \([24]\). In this paper, we want to address the dynamical aspects related to the geodesic flow on the tangent bundle in any dimension. Crampon developed many aspects of this point of view in his papers \([15, 16, 17, 18]\). There are several measures invariant under the geodesic flow, but we single out one measure, the Sinai-Ruelle-Bowen measure, abbreviated SRB measure. That measure provides, especially in dimension two, some deep insight concerning the shape of the boundary at infinity. We will elaborate on this in the text.

The most studied invariant measure is the Bowen-Margulis measure. A key property used by Crampon is that this measure is reversible, i.e., it is invariant under the flip map \(\sigma(x, [v]) = (x, [-v])\). The most eminent consequence is that the sum of the positive Lyapunov exponents associated to that measure is \(n - 1\), as in the hyperbolic metric case.

Using the Ruelle inequality for the Bowen-Margulis measure, Crampon deduces that the topological entropy is less than or equal to \(n - 1\) with equality only in the hyperbolic case. One key feature of the SRB measure is that the Ruelle inequality becomes an equality, known as the Pesin formula. When there is an invariant volume form, that form gives, after normalization, the density of the SRB measure. But we know from Benoist \([3]\) that if the convex structure is not the hyperbolic model, then there is no such an invariant volume form for the flow. Nevertheless, in general the SRB measure is characterised by the fact that its conditional measures on unstable leaves are absolutely continuous to the Lebesgue measure (Ledrappier-Young \([29]\)). This is why it turns out to be a key ingredient to better understand the geometry of projective structures. We also observe a global irreversible effect along the orientation of time. We will elaborate on this in Corollary \([12, 3]\).

**Theorem 1.1.** Let \(M\) be a closed manifold of dimension \(n\). Then the map \(h_{SRB} : P_n(M) \to \mathbb{R}\) is continuous, where \(h_{SRB}\) denotes the Sinai-Ruelle-Bowen measure entropy of the geodesic flow defined on the convex real projective manifold.

Given a strictly convex real projective manifold \(M\) and the geodesic flow invariant SRB measure \(\mu_{SRB}\), by ergodicity of the SRB measure, there exists a set \(W_{SRB} \subset HM = (TM \setminus \{0\})/\mathbb{R}_+^*\) with \(\mu_{SRB}(W_{SRB}) = 1\), and \(\chi_1, \cdots, \chi_p \in \mathbb{R}\) called the Lyapunov exponent relative to the SRB measure, such that, for any \(w \in W_{SRB}\), there exists a geodesic flow...
invariant decomposition $THM = \oplus E_i$ and for any $v \in E_i$, $\chi_i(w, v) = \chi_i$, where $\chi_i(w, v)$ are Lyapunov exponents. See Sections 2 and 2.2 for definitions and properties.

**Corollary 1.2.** Let $M_t$ be a smooth family of real projective structures on $M$. Then

1. The sum $\chi^+$ of the SRB positive Lyapunov exponents vary continuously in $t$.
2. The entropy $h_{SRB}$ of the SRB measure satisfies inequality
   
   $$h_{SRB} = n - 1 + \frac{1}{2} \eta \leq n - 1$$

   where $\eta$ is the SRB almost sure value of $\eta(w) = \sum \eta_i(w) \text{dim} E_i(w)$, the sum of parallel Lyapunov exponents. By Ruelle inequality, $\eta \leq 0$ and the equality holds if and only if the structure is hyperbolic.
3. (Irreversibility) Let $dvol$ be any continuous volume form. Then
   
   $$\lim_{s \to \infty} \frac{1}{s} \log \left( \frac{d(\phi^s)^*(dvol)}{dvol} \right) = \sum \eta_i \text{dim} E_i = \eta.$$

   As shown by Crampon [18], the Lyapunov exponents have to do with the convexity of the boundary of $\Omega$. It is particularly meaningful when the dimension of $\Omega$ is 2. The boundary $\partial \Omega$ in the neighborhood of a point $p$ can be written as the graph of a convex function $f$ near the origin. Such a function $f$ is said to be *approximately $\alpha$-regular* at $p$ for $\alpha \in [1, \infty]$, if

   $$\lim_{t \to 0} \frac{\log \left( \frac{f(t) + f(-t)}{2} \right)}{\log |t|} = \alpha(p).$$

   This quantity is invariant under affine and projective transformations. Approximately $\alpha$-regular means if $\alpha < \infty$ that the function behaves like $|t|^\alpha$ near the origin.

**Corollary 1.3.** There is a set $F_{SRB} \subset \partial \Omega$ of full Lebesgue measure and a real number, $2 \leq \alpha_{SRB} < \infty$, called the regular exponent for the boundary, such that for any $p \in F_{SRB}$ we have

$$\alpha(p) = \alpha_{SRB}$$

The map $\alpha_{SRB} : P_2(M) \to \mathbb{R}$ is continuous.

Furthermore, we have

$$\chi^+ \alpha = 2.$$
Remarks.

- This shows that if a stritcly convex projective structure is not the standard hyperbolic structure then the boundary is “very” flat. In particular for almost every point $p$ on the boundary the local representing graph admits at least a second derivative at $p$ that vanishes. But the boundary is nowhere $C^2$. This remark makes more precise the work of Benoist [3] showing that the curvature of the boundary is localized on a set of null Lebesgue measure.

- In higher dimensions, similar exponents were introduced by Crampon and the general statement that we obtain is that their harmonic mean varies continuously.

- Something worth noticing and a bit surprising is there exists no ideal regular odd-sided geodesic polygon if $\Omega$ is not conic. See the proof of Corollary [1,3] and remark therein.

Acknowledgement. We thank F. Ledrappier for numerous discussions.

2. PRELIMINARIES

2.1. Projective structure. Let $M$ be an $n$-dimensional closed manifold equipped with a strictly convex projective structure so that $D : \tilde{M} \to \mathbb{RP}^n$ is a developing map with $D(\tilde{M}) = \Omega$. Then it inherits a Hilbert metric defined in the following way. Let $x, y \in M$. Then choose $\tilde{x}, \tilde{y}$ in the same fundamental domain, and define $d(x, y) := d_\Omega(D(\tilde{x}), D(\tilde{y}))$ where the Hilbert metric $d_\Omega$ defined as below and the corresponding Finsler norm on $T\Omega$ is denoted by $F$. More precisely, for $x \neq y \in \Omega$, let $p, q$ be the intersection points of the line $\overline{xy}$ with $\partial \Omega$ such that $p, x, y, q$ are in this order. The Hilbert distance is defined by

$$d_\Omega(x, y) = \frac{1}{2} \log \left( \frac{|p - y||q - x|}{|p - x||q - y|} \right)$$

where $|\cdot|$ is a Euclidean norm in an affine chart containing $\Omega$. This metric coincides with the hyperbolic metric if $\partial \Omega$ is a conic. Note that the Hilbert metric on $M$ also depends on the boundary of $\Omega$. The Hilbert metric is Finsler rather than Riemannian. The Finsler norm $F = ||\cdot||$ is given, for $x \in \Omega$ and a vector $v$ at $x$, by

$$||v||_x = \left( \frac{1}{|x - p^-|} + \frac{1}{|x - p^+|} \right) |v|$$

where $p^\pm$ are the intersection points of the line with $\partial \Omega$, defined by $x$ and $v$ with the obvious orientation, and where $|\cdot|$ is again a Euclidean norm.
If $\Omega$ admits a compact quotient manifold $M = \Omega / \Gamma$, then $\partial \Omega$ is $C^{1+\alpha}$, $\Gamma$ is Gromov hyperbolic and the geometry behaves like a negatively curved case. See [3, 5].

For a given $w = (x, [\xi]) \in H\Omega = (T\Omega \setminus \{0\})/\mathbb{R}_+$, the unstable manifold $W^{su}$ passing through $w$ is defined to be

$$W^{su}(w) = \{ (y, [\phi]) \in H\Omega | \xi(-\infty) = \phi(-\infty), y \in H_{\sigma_w} \}.$$ 

Here $\xi(-\infty)$ denotes $\gamma_\xi(-\infty)$ where $\gamma_\xi$ is the geodesic determined by $\xi$, and $\sigma_w = (x, [-\xi])$ is a flip map, and $H_w$ is the horosphere based at $\xi(\infty)$ passing through $x$. Similarly one can define a stable manifold

$$W^{ss}(w) = \{ (y, [\phi]) \in H\Omega | \xi(\infty) = \phi(\infty), y \in H_w \}.$$ 

These stable and unstable manifolds are $C^1$ if $\partial \Omega$ is $C^1$.

The tangent spaces of $W^{su}$ and $W^{ss}$ form unstable and stable vectors in $TH\Omega$, i.e., along the geodesic flow, they expand or decay exponentially. All the objects defined above descend to the quotient manifold $M$ and it is known [3] that the geodesic flow on $HM$ is Anosov with invariant decomposition

$$THM = \mathbb{R}X \oplus E^s \oplus E^u,$$

where $X$ is the vector field generating the geodesic flow.

2.2. Lyapunov exponents and Sinai-Ruelle-Bowen measure.

2.2.1. Lyapunov exponent. Let $\phi = \phi^t$ be a $C^1$ flow on a Riemannian manifold $W$. A point $w \in W$ is said to be regular if there exists a $\phi^t$-invariant decomposition

$$TW = E_1 \oplus \cdots \oplus E_p$$

along $\phi^t w$ and real numbers

$$\chi_1(w) < \cdots < \chi_p(w),$$

such that, for any vector $Z_i \in E_i \setminus \{0\}$,

$$\lim_{t \to \pm\infty} \frac{1}{t} \log \| d\phi^t(Z_i) \| = \chi_i(w),$$

and

$$\lim_{t \to \pm\infty} \frac{1}{t} \log |\det d\phi^t| = \sum_{i=1}^p \dim E_i \cdot \chi_i(w).$$

(1)

The numbers $\chi_i(w)$ associated with a regular point $w$ are called the Lyapunov exponents of the flow at $w$. Due to Oseledets’ multiplicative ergodic theorem [32], the set of regular points has full measure.
Theorem 2.1. Let $\phi$ be a $C^1$ flow on a Riemannian manifold $W$ and $\mu$ a $\phi^t$-invariant probability measure. If
\[ \frac{d}{dt}|_{t=0} \log ||d\phi^t|| \in L^1(W, \mu), \]
then the set of regular points has full measure.

2.3. In the case of convex projective structures. There exists an extended Finsler norm $\bar{F}$ on $HM = (TM\setminus\{0\})/\mathbb{R}^*_+$ and the Lyapunov exponent is defined to be
\[ \lim_{t \to \pm \infty} \frac{1}{t} \log \bar{F}(d\phi^t(Z_i)) = \chi_i(w). \]

Let $\Omega$ be a strictly convex domain with $C^1$ boundary equipped with a Hilbert metric. There is a notion of parallel transport $T^t$ due to Foulon [20, 21]. The parallel Lyapunov exponent of $v \in T_x\Omega$ along $\phi^t(x, [\psi])$ is defined to be
\[ \eta((x, [\psi]), v) = \lim_{t \to \infty} \frac{1}{t} \log F(T^t(v)). \]

Then Crampon [17] showed that a point $w = (x, [\psi]) \in H\Omega$ is regular if and only if there exists a decomposition
\[ T_x\Omega = \mathbb{R}\psi \oplus E_0(w) \oplus (\bigoplus_{i=1}^p E_i(w)) \oplus E_{p+1}(w), \]
and real numbers
\[ -1 = \eta_0(w) < \eta_1(w) < \cdots < \eta_p(w) < \eta_{p+1} = 1, \]
such that for any $v_i \in E_i \setminus \{0\}$,
\[ \lim_{t \to \pm \infty} \frac{1}{t} \log F(T^t_w(v_i)) = \eta_i(w), \]
and
\[ \lim_{t \to \pm \infty} \frac{1}{t} \log |\det T^t_{w}| = \sum_{i=0}^{p+1} \dim E_i(w) \eta_i(w) := \eta(w). \]
Here $E_0$ and $E_{p+1}$ could be zero.

The relation between Lyapunov and parallel Lyapunov exponents is; for stable $Z^s$ and unstable $Z^u$ vectors in $T_wH\Omega$,
\[ \chi(Z^s) = -1 + \eta(w, d\pi(Z^s)), \chi(Z^u) = 1 + \eta(w, d\pi(Z^u)), \]
where $\pi : H\Omega \to \Omega$ is the projection. See Proposition 1 of [17] for details.

Remark 2.2. The reversibility of the geodesic flow induces for regular points a special property observed by Crampon namely
\[ \eta((x, [\psi]), v) = -\eta(\sigma(x, [\psi]), \sigma(v)) \]
This means that if a trajectory of the flow is regular then the two opposite boundaries at $\infty$ are strongly related.

Hence one can summarize these facts as:

$\mathcal{TH} \Omega = \mathbb{R} X \oplus (\oplus_{i=0}^{p+1} (E_i^s \oplus E_i^u))$

where $E_i^s = J^X(E_i^u)$ for some pseudo-complex structure $J^X$ and $\chi^-_i$ is a Lyapunov exponent for $E_i^s$, $\chi^+_i$ for $E_i^u$, $E_i = E_i^s \oplus E_i^u$

$\chi^+_i = 1 + \eta_i$, $\chi^-_i = -1 + \eta_i$, $\chi^+_i = \chi^-_i + 2$,

$-2 = \chi^-_0 < \chi^-_1 < \cdots < \chi^-_{p+1} = 0 = \chi^+_0 < \chi^+_1 < \cdots < \chi^+_{p+1} = 2$.

Note that

$\chi^+ = \sum \dim E^u_i \chi^+_i = \sum \dim E^u_i (1 + \eta_i) = \sum \dim E^u_i + \sum \dim E^u_i \eta_i$

$= (n - 1) + \sum \dim E^u_i \eta_i$.

But

$\eta = \sum \dim E^u_i \eta_i = 2 \sum \dim E^u_i \eta_i$.

Hence

(4) \[ \chi^+ = (n - 1) + \frac{1}{2} \eta. \]

The Lyapunov exponents have to do with the convexity of the boundary of $\Omega$. For 2-dimensional $\Omega$, the neighborhood of each point of the boundary $\partial \Omega$ can be written as the graph of a convex function $f$ near the origin. Such a function $f$ is said to be approximately $\alpha$-regular at the origin for an $\alpha \in [1, \infty]$, if

$\lim_{t \to 0} \frac{\log \frac{f(t) + f(-t)}{2}}{\log |t|} = \alpha.$

This quantity is invariant under affine and projective transformations. Approximately $\alpha$-regular for $\alpha$ finite means that the function behaves like $|t|^\alpha$ near the origin.

Let $\Omega$ be a strictly convex open domain in $\mathbb{R}^2\mathbb{P}$ with $C^1$ boundary. Let $\xi \in \partial \Omega$. Let $w = (x, [\psi]) \in \mathcal{H} \Omega$ be such that $\psi(\infty) = \xi$. Let $\mathcal{H}_w$ be a horocycle based at $\xi$ and passing through $x$. It is shown in [17] (Theorem 1) (or [15] (Proposition 3.4.12)) that for any $v(w) \in T_x \mathcal{H}_w$,

(5) \[ \eta(w, v(w)) = \frac{2}{\alpha(\xi)} - 1. \]
Remark 2.3. According to the remark about reversibility, for all regular trajectory \((x, [\psi])\) we have

\[ \frac{1}{\alpha(\xi)} + \frac{1}{\alpha(\sigma(\xi))} = 1 \]

where \(\sigma(\xi) = \psi(-\infty)\).

Periodic orbits are regular trajectories, and all these quantities can be expressed via the representation. Suppose \(\gamma\) is a hyperbolic isometry whose eigenvalues are \(\lambda_1 > \lambda_2 > \lambda_3\) and \(\gamma^+ = \psi(\infty)\). Then it is shown in Proposition 5.5 of [16] (or in Section 3.6 of [15]) that

\[ \eta(w, v(w)) = -1 + 2 \frac{\log \lambda_1}{\log \frac{\lambda_2}{\lambda_3}}, \]

hence

\[ \alpha(\gamma^+)^{-1} = \frac{\log \frac{\lambda_1}{\lambda_2}}{\log \frac{\lambda_1}{\lambda_3}}. \]

2.3.1. Invariant measures. For a geodesic flow on \(H\Omega\), the maximal entropy \(h_\mu(\phi)\) of the probability measure \(\mu\) is known to be realized at the Bowen-Margulis measure. This entropy is equal to the topological entropy \(h_{\text{top}}(\phi)\) of the geodesic flow \(\phi\) and it is also equal to the exponential growth of the lengths of closed geodesics:

\[ \lim_{R \to \infty} \frac{\log \#\{[\gamma] | \ell(\gamma) \leq R\}}{R}. \]

This is again equal to the critical exponent of the associated Poincaré series. It is proved by Crampon [16] that the entropy of Bowen-Margulis measure of strictly convex real projective structures on a closed surface is between 0 and 1. But there exists another invariant measure called Sinai-Ruelle-Bowen measure, abbreviated SRB measure. It is characterized as follows. First we recall a fundamental theorem known as Margulis-Ruelle inequality:

\[ \text{Theorem 2.4. Let } M = \Omega/\Gamma \text{ be a strictly convex compact projective manifold. Let } \mu \text{ be a geodesic flow invariant probability measure on } HM. \text{ Then} \]

\[ h_\mu(\phi) \leq \int \chi^+ d\mu, \]

where \(\chi^+ = \sum \dim E_i \cdot \chi_i^+\) denotes the sum of positive Lyapunov exponents.
An invariant measure that achieves equality in Margulis-Ruelle inequality is called Sinai-Ruelle-Bowen measure.

Another description of this measure $\mu_{SRB}$ is: there exists a set $V$ of full Lebesgue measure such that for each continuous function $f : M \to \mathbb{R}$ and for every $x \in V$,

$$\lim_{T \to \infty} \frac{1}{T} \int_0^T f(\phi^s(x))ds = \int f d\mu_{SRB}.$$ 

Ledrappier-Young [29] proved the following characterization of a Sinai-Ruelle-Bowen measure:

**Theorem 2.5.** Let $M$ be a compact, strictly convex real projective manifold. Then the geodesic flow invariant measure $\mu$ is the SRB measure if and only if it has absolutely continuous conditional measures on unstable manifolds.

2.4. **Deformation of the representation.** Ehresmann-Thurston described the deformation of geometric structures in terms of the deformation of developing maps. This theory is rigorously rephrased by Bergeron-Gelander [6].

**Proposition 2.6.** If $\rho_t : \pi_1(M) \to SL(n, \mathbb{R})$ is a smooth deformation of strictly convex real projective structures, then there exists a continuous associated deformation $D_t$ of the developing map such that its image $\Omega_t$ and the boundary $\partial \Omega_t$ in Hausdorff topology vary continuously, hence the Hilbert metric $d_t$ and the geodesic flow $\phi^t$ vary continuously. Furthermore the convexity forces also the continuity of $\partial \Omega_t$ in $C^1$-topology.

**Proof.** For any two points $x, y \in M$, and two lifts $\tilde{x}, \tilde{y} \in \tilde{M}$, we know that $D_t \tilde{x}, D_t \tilde{y}$ vary continuously according to Bergeron-Gelander. Then the line connecting $D_t \tilde{x}, D_t \tilde{y}$ varies continuously. Now we need to determine two points on $\partial \Omega_t$ where this line intersects and show that they vary continuously. For each $\gamma \in \pi_1(M)$, let $\gamma^+_t$ be the line corresponding to the largest eigenvalue, $\gamma^-_t$ the line corresponding to the smallest eigenvalue, and $E^+_t$ the sum of eigenspaces complementary to $\gamma^-_t$. Then it is known that $\gamma^+_t \in \partial \Omega_t$ and $T_{\gamma^+_t} \partial \Omega_t = E^+_t$. Since $\rho_t$ varies continuously, $\gamma^+_t$ and $E^+_t$ vary continuously. For any given finite set $\gamma_1, \cdots, \gamma_k \in \pi_1(M)$, $\Omega_t$ is included in the convex set formed by $\cap HE^+_t$ where $HE^+_t$ is the half space containing $\Omega_t$. By enlarging the set, we can see that $\Omega_t$ and $\partial \Omega_t$ vary continuously. $\square$

Note that each point in $\mathcal{P}_n(M)$ is a class of $(D, \rho)$ where $D : \tilde{M} \to \mathbb{R}P^n$ is a developing map and $\rho : \pi_1(M) \to PGL(n + 1, \mathbb{R})$ is a holonomy representation. To each such pair $(D, \rho)$ are associated $\Omega_D = D(\tilde{M})$,.
the Hilbert metric and the geodesic flow, hence \( h^D_{SRB} \) the SRB entropy. If two structures \((D, \rho)\) and \((D', \rho')\) are equivalent, then \( \rho \) and \( \rho' \) are conjugate and \( \Omega_D \) and \( \Omega_{D'} \) are diffeomorphic by a projective map. Since the entropy is invariant under conjugacy, we have a well-defined map \( h_{SRB} : \mathcal{P}_n(M) \to \mathbb{R} \). It is known that \( \mathcal{P}_n(M) \) is a component of a character variety by Benoist [3]. Hence it is enough to study the continuity along a continuous path.

3. Continuity of the Sinai-Ruelle-Bowen measure entropy and application

Throughout this section \( M \) is a compact smooth manifold, \( D : \tilde{M} \to \mathbb{R}P^n \) is a developing map, and \( \rho : \pi_1(M) \to PSL(n+1, \mathbb{R}) \) is the holonomy map of a strictly convex real projective structure. Let \( g^h \) be the Hilbert metric of \( \Omega = D(\tilde{M}) \), \( F \) the Hilbert norm on \( TM \), and \( \phi^t \) the geodesic flow associated with the Hilbert metric. Then it is known that this flow is Anosov and it is \( C^{1,\alpha} \) due to Benoist [3].

Let \( g \) be a \( C^\infty \)-Riemannian metric on \( M \). Suppose \( \psi^t \) is a flow with the same trajectory as \( \phi^t \) but unit speed with respect to \( g \). If

\[
X = \frac{d\phi^t}{dt}, \\
Z = \frac{d\psi^t}{dt},
\]

then

\[
X = mZ.
\]

We know that

\[
F(d\pi X) = g(d\pi Z) = 1
\]

where \( \pi : HM \to M \) is a projection. Then

\[
1 = m(x, [v])F(d\pi(Z(x, [v])),
\]

and set

(7)

\[
\beta = m^{-1} = F(d\pi Z)
\]

Lemma 3.1. \( \psi^t \) and \( Z \) are \( C^\infty \) and \( \phi^t \) and \( X \) are \( C^{1,\alpha} \). Furthermore \( \beta : HM \to \mathbb{R}^+ \) is \( C^{1,\alpha} \).

Proof. The geodesic foliation of a strictly convex projective structures is smooth because locally it is the foliation by straight lines in a projective chart. This was previously observed by Benoist. The fact that \( \phi^t \) is \( C^{1,\alpha} \) is also due to Benoist. The \( C^{1,\alpha} \)-ness comes from the \( C^{1,\alpha} \)-ness of Finsler norm, which is again due to the \( C^{1,\alpha} \)-ness of \( \partial \Omega \). The generator of the geodesic flow, \( X \) is also \( C^{1,\alpha} \), being tangent to a smooth foliation and being normalized with respect to the Hilbert metric. But if we reparameterize the flow, using a smooth Riemannian metric, the
resulting vector field $Z$ is smooth, so it is for the induced flow. However $F$ is $C^{1,\alpha}$, hence $\beta$ is $C^{1,\alpha}$.

We have the following theorem about the change of time, due to Anosov and Sinai [2, 33].

**Theorem 3.2.** If $\phi$ is a $C^1$-Anosov flow and $\psi$ is obtained from $\phi$ by multiplying a positive $C^1$-function on the speed, then $\psi$ is again Anosov.

**Remark 3.3.** In our case, $\psi$ is a $C^\infty$-Anosov flow. This is the $C^\infty$ foliation by straight lines with $C^\infty$ parametrization. Now using the result of Parry [33] we get,

$$\mu^\phi_{SRB} = \beta \mu^\psi_{SRB} / \int_{HM} \beta d\mu^\psi_{SRB}$$

and using a theorem of Abramov [1]

$$h_{SRB}(\phi) = h_{SRB}(\psi) / \int_{HM} \beta d\mu^\psi_{SRB}.$$ 

The continuity of the SRB entropy for $C^\infty$ Anosov flow is due to Contreras [14] (theorem B). 

**Theorem 3.4.** If $\lambda$ is a $C^r$-Anosov flow, there exists a neighborhood $U$ of $\lambda$ in $C^r$ topology such that the function $\psi \mapsto h_{SRB}(\psi)$ is $C^{r-2}$.

To control the denominator let us recall that the SRB measure is the unique equilibrium state associated with the infinitesimal volume expansion which is here a smooth function. Since the scaling factor $\beta$ is $C^{1,\alpha}$, we may again invoke [14] (theorem C) that we may specialize to SRB measures as follows

**Theorem 3.5.** If $\lambda$ is a $C^r$-Anosov flow, there exists a neighborhood $U$ of $\lambda$ in $C^r$ topology such that if $\mu_\lambda$ is its SRB measure then for any $0 < \alpha < 1$ small enough the map $\lambda \in U \rightarrow \mu_\lambda \in C^\alpha(M, \mathbb{R})^*$ is $C^{r-1}$.

Now we prove that the entropy of SRB along a smooth deformation varies continuously.

**Theorem 3.6.** Let $\rho_t : \pi_1(M) \rightarrow SL(n+1, \mathbb{R})$ be a smooth deformation of strictly convex projective structures. Then $t \mapsto h_{SRB}(\rho_t)$ is a continuous map.

**Proof.** Since $\Omega_t = D_t(\widetilde{M})$ is continuously determined by $\rho_t$ as in Section 2.4 both $\Omega_t$ and $\partial\Omega_t$ depend continuously on $t$ with respect to the Hausdorff topology. Fix a $C^\infty$ Riemannian metric on $M$. Now since $\rho_t$
depends smoothly on \( t \), the reparameterized geodesic flow \( \psi_t \) depends smoothly on \( t \). By Equation (7),

\[
\beta_t = F_t(d\pi Z_t)
\]

is continuous in \( t \). Then, by Equation (9), and since \( h(\psi_t)_{SRB} \) varies continuously by Theorem 3.4, it is enough to show that the denominator varies continuously.

**Lemma 3.7.** Let \( \alpha \) be as in theorem 3.5. If \( f_i \in C^\alpha(M, \mathbb{R}) \) converges to \( f \in C^\alpha(M, \mathbb{R}) \) in \( C^0 \) topology and probability measures \( \mu_i \) converge to \( \mu \) in \( C^\alpha(M, \mathbb{R})^* \), then

\[
\int_M f_i d\mu_i \to \int_M f d\mu.
\]

**Proof.**

\[
| \int f_i d\mu_i - \int f d\mu | \leq | \int f_i d\mu_i - \int f d\mu_i | + | \int f d\mu_i - \int f d\mu |
\]

\[
\leq |f_i - f|_{\infty} + | \int f d(\mu_i - \mu) |.
\]

The first term goes to zero since \( f_i \to f \) in \( C^0 \) topology and the second term goes to zero since \( \mu_i \to \mu \) in \( C^\alpha(M, \mathbb{R})^* \).

**Corollary 3.8.** Along the smooth deformation of convex real projective structures, the sum \( \eta \) of parallel Lyapunov exponent varies continuously.

**Proof.** Since the geodesic flow \( \phi \) is ergodic with respect to the SRB probability measure \( \mu \), and the measurable function \( \chi^+ \) is \( \phi \)-invariant, \( \chi^+ \) is almost constant. Furthermore, by the property of the SRB measure, \( h_{\mu}(\phi) = \int \chi^+ d\mu \), the entropy \( h_{\mu}(\phi) \) must be equal to \( \chi^+ \). Since the entropy varies continuously along the smooth deformation, \( \chi^+ \) varies continuously along the smooth deformation. The claim follows from Equation (2).

In particular, in the case of dimension 2 surfaces, it can be stated as

**Corollary 3.9.** Along the smooth deformation of the convex structure, \( \alpha \) varies continuously.

Now we give a proof for Corollary 1.2
Proof. The continuity follows from the main Theorem\[1.1\] and the other claims follow from results in \[15\] and equalities \(\chi^+_i = 1 + \eta_i, \chi^-_i = -1 + \eta_i, \chi^+\alpha = 2\). (4) Let \(\omega\) be a volume form. Note that \(THM = E^u \oplus E^s \oplus \mathbb{R}X\) where \(X\) is the vector field generating the geodesic flow \(\phi^s\) of the Hilbert metric. Choose a Riemannian metric \(g\) so that for each point \(w \in T_wHM, e_1(w), \ldots, e_{n-1}(w)\) are bases of \(E^u(w)\) consisting of unit vectors, and \(b_1(w), \ldots, b_{n-1}(w)\) bases of \(E^s(w)\) consisting of unit vectors. Since \(M\) is compact and \(\omega\) is a continuous volume form,

\[
\omega(e_1, \ldots, e_{n-1}, b_1, \ldots, b_{n-1}, X) < N
\]
on \(HM\) for some positive \(N\). Since the flow \(\phi^s\) preserves the splitting of \(E^u, E^s\),

\[
d\phi^s(e_i(w)) \in E^u(\phi^s(w)), d\phi^s(b_i(w)) \in E^s(\phi^s(w)), d\phi^s(X) = X.
\]

Then

\[
\lim_{s \to \infty} \frac{1}{s} \log \left( \frac{d(\phi^s)^*(\omega)(e_i, b_i, X)}{\omega(e_i, b_i, X)} \right) = \lim_{s \to \infty} \frac{1}{s} \log \left( \frac{\omega(d\phi^s(e_i, b_i, X))}{\omega(e_i, b_i, X)} \right) = \lim_{s \to \infty} \frac{1}{s} \log(|\det d\phi^s|) = \sum \chi_i \dim E_i = \eta.
\]

The last equality follows from the fact that \(\chi^+_i = 1 + \eta_i, \chi^-_i = -1 + \eta_i\) in Equation (3) and the second to last equality follows from Equation (1).

Proof. For Corollary \[1.3\] and geometric discussion. By ergodicity of the SRB measure, there exists a flow invariant set \(W_{SRB} \subset HM\) of full measure with respect to the SRB measure on which the sum \(\chi^+\) of positive Liapunov exponents is constant and coincide with the value of the SRB entropy. Furthermore, this shows that the sum of exponents \(\eta\) for the parallel transport is, on that set, a non positive number \(\eta \leq 0\) such that \(h_{SRB} = n - 1 + \frac{1}{2}\eta\) according to Eqn (4) and Crampon’s inequality for any invariant measure. We observe that \(\eta = 0\) is equivalent to being Riemannian hyperbolic case. In the hyperbolic case every orbit of the flow is regular. We will observe that this is no longer true when \(\eta < 0\), which is what we will assume in the sequel. The set \(W_{SRB} \subset HM\) being of full SRB measure, for almost all unstable leaf with respect to the invariant transverse measure induced by the SRB measure, almost every trajectory with respect to the conditional measure on that unstable leaf is regular and the sum of exponents for the parallel transport is \(\eta\). We know that the conditional measure on
unstable leaves of the SRB measure are absolutely continuous with respect to the Lebesgue measure therefore for each such unstable leaf \( L^u(x, [v]) \) there exists a subset of full Lebesgue measure \( S_{L^u(x, [v])} \subset \partial \Omega \) such that for any boundary point \( \xi \in S_{L^u(x, [v])} \) is approximately regular with exponent

\[
\alpha(\xi) = \frac{2}{1 + \frac{\eta}{2}} \geq 2
\]

(10)

Again, the equality is achieved only in the hyperbolic case. We can go further and observe some strange effect that will shed some light on the transversal measure of the SRB measure. Such an unstable leaf is associated to a point \( \xi^- \) on the boundary such that all the geodesics under consideration emanate from that point at \(-\infty\). However we know that any regular geodesic is also also regular by reversing time and then all the reversed geodesics have opposite parallel transport exponent. Then the approximately regular exponent at \( \xi^- \) is \( \alpha(\xi^-) = \frac{2}{1 + \frac{\eta}{2}} \leq 2 \). Such points have a measure 1 with respect to the transverse SRB measure which is therefore orthogonal to Lebesgue as soon as it is not hyperbolic. To sum up, there exists on the boundary a set of full Lebesgue measure of points on which the convex is “flatter” than a conic and a zero Lebesgue measure of points where the convex is “sharper” than a conic. A funny remark is that when \( \eta < 0 \) there is no triangle with regular geodesics but there are many even sided regular polygons with that regularity.

\[ \square \]
