Abstract

AIM: To study the prevalence of persistent post-surgical pain (PPSP) and neuropathic pain (NP) after total knee replacement (TKR).

METHODS: MEDLINE and Embase databases were searched for articles published until December 2014 in English language. Published articles were included if they referred to pain that lasts at least 3 mo after primary TKR for knee osteoarthritis, and measured pain with pain specific instruments. Studies that referred to pain caused by septic reasons and implant malignment were excluded. Both prospective and retrospective studies were included and only 14 studies that match the inclusion criteria were selected for this review.

RESULTS: The included studies were characterized by the heterogeneity on the scales used to measure pain and pre-operative factors related to PPSP and NP. The reported prevalence of PPSP and NP seems to be relatively high, but it varies among different studies. There is also evidence that the prevalence of post-surgical pain is related to the scale used for pain measurement. The prevalence of PPSP is ranging at 6 mo from 16% to 39% and at 12 mo from 13.1% to 23% and even 38% of the patients. The prevalence of NP at 6 mo post-operatively is ranging from 5.2% to...
Although the cause of PPSP is not known, it seems that represents an important cause for patients’ dissatisfaction.

**CONCLUSION:** No firm conclusions can be reached regarding the prevalence of PPSP and NP and the related factors due to the heterogeneity of the studies.

**Key words:** Total knee replacement; Pain; Chronic pain; Neuropathic pain; Post-operative pain; Persistent post-surgical pain

Core tip: Persistent post-surgical pain (PPSP) is reported in a significant proportion of patients after total knee replacement. This proportion varies between the different studies and different factors have been implicated including the instrument used to measure pain. It is also obvious that in some of these patients the pain is neuropathic (NP) in origin or the NP pain coexists. Nevertheless, due to the heterogeneity of the studies, mainly on the scales used to assess pain and preoperative factors, we are unable to reach firm conclusions concerning the prevalence, and the risk factors of PPSP pain after total knee replacement. Additional studies focused on the prevalence and risk factors related to PPSP are needed.

**INTRODUCTION**

Total knee replacement (TKR) is a treatment of knee osteoarthritis to alleviate pain symptoms and improve mobility and physical functioning when other conservative treatments have failed. It is a very common and successful procedure since 1970s for late stage osteoarthritis and there is a continuously increasing number in demand for primary TKR performed worldwide each year. However, not all patients are satisfied after TKR. Pain after TKR is stronger determinant of satisfaction than function. An unfavorable pain outcome was seen in at least 8.0% and up to 26.5% of patients and contribute to functional disability after TKR.

From the post-surgical pain that is a result of a specific cause, some patients suffer from a persistent post-surgical pain (PPSP) with no specific origin that represents an important cause for patients’ dissatisfaction. Although the cause of PPSP is not known, it seems that some of the patients with PPSP after TKR suffer from neuropathic pain (NP). The International Association for the Study of Pain (IASP) defines: (1) as PPSP the pain that is being developed after surgery and exists beyond the time for normal healing and is present for at least 3-6 mo; and (2) NP is also defined by the IASP as the pain caused by a lesion or a disease of the somatosensory nervous system (IASP website, http://www.iasp-pain.org/). A wide variety of scores-tools have been used in order to assess the outcome postoperatively. Almost all scores or instruments -either objective (clinician-based) or subjective (patient-reported) or disease specific - being used for the study of the outcome, function and satisfaction after TKR, include some kind of pain assessment. However, a standard definition of pain severity at follow-up considered a difficult issue to be applied and the need to improve assessment and measurement of musculoskeletal pain in the clinical setting is recognized.

The purpose of this study is to present a review of the existing literature concerning the existence of PPSP and NP after TKR for at least 3 mo, including studies with main purpose the prevalence of the PPSP and NP after TKR using pain-specific instruments and not through other scores or instruments measuring functional outcome.

**MATERIALS AND METHODS**

**Literature search**

MEDLINE and Embase databases were searched for articles published until December 2014. The keywords “TKR”, “total knee arthroplasty”, “chronic postoperative pain”, “NP” and synonyms were used to maximize the efficiency of the search. Both prospective and retrospective studies were included.

**Inclusion and exclusion criteria**

Published articles were included only if they referred to pain that lasts at least 3 mo after primary TKR and if the main reason of TKR was knee OA. Studies were excluded if they were abstracts, case studies, reviews, editorials and if they referred to pain caused by septic reasons and implant malalignment. Studies that assessed a mixed cohort of patients (e.g., knee and hip replacement patients) were included in the review and only data relevant to the TKR patients were extracted. Studies in other language than English were excluded.

A total of 112 articles were found. Only 14 studies that match the inclusion criteria and measured pain with pain specific instruments were selected for this review.

**RESULTS**

**PPSP after TKR (Table 1)**

**Studies:** We identified 5 prospective and 3 retrospective studies. Three of the studies found to have as primary aim the documentation of the existence and the prevalence of PPSP after TKR, while another

| Ref. | Design/patients | Aim of the study | Scores-scales | Follow-up | Pain | Factors |
|------|-----------------|------------------|---------------|-----------|------|---------|
| Brander et al[19] Prospective n = 116 | To describe the natural history of pain after TKR To identify factors predicting excessive post-surgical pain | VAS and other measures of patient health | Pre-op. | Pre-op.: 72.3% | Factors related with post-op pain at 12 mo (1) Pre-operative pain; and (2) Pre-operative depression and anxiety |
| Forsythe et al[20] Prospective n = 55 | To document: the prospective pain experience following TKR To determine if: (1) comorbidities; (2) preoperative pain; or (3) preoperative pain catastrophizing scores are predictors of chronic pain after TKR | MPQ PCS | Pre-op. | Significant reduction only between pre-op and 3-mo post-op values. After 3-mo pain had reached a plateau Pain catastrophizing scores didn't show any significant differences | Predictive of chronic postoperative pain: (1) No. of comorbidities and (2) Pre-operative pain catastrophizing scores |
| Ritter et al[21] Retrospective n = 7326 | To quantify the effect of sex on the clinical outcome and survivorship of a specific TKR AGC, Biomet, Warsaw, Ind | KSS PS | Throughout 5 yr Pain after TKR was less for men but there was no statistically significant difference between men and women | Improvement after TKR is similar for men and women No significant difference in post-operative pain between men and women | Significant and independent postoperative determinants of number of PPSP: (1) No. of pain problems elsewhere; and (2) The presence of major depression |
| Wykle et al[22] Retrospective n = 632 | To assess the (1) prevalence; (2) severity; (3) sensory qualities; and (4) postoperative determinants of persistent pain after primary THR and TKR | WOMAC Pain Scale SFMPQ pD-Q Two-item Patient Health Questionnaire (PHQ-2) | Median: 41 mo Range: 34-49 mo Persistent post-surgical pain (PPSP): 44% Severe-extreme PPSP: 15% Constant PPSP: 5% Likely neuropathic pain: 6% | No significant difference in post-operative pain between men and women Significant and independent postoperative determinants of number of PPSP: (1) No. of pain problems elsewhere; and (2) The presence of major depression |
| Polkowski et al[23] Prospective n = 309 | To explore the relationship between early-grade preoperative OA with pain and dissatisfaction after TKR | Group A: Pain after TKR Group B: Consecutive series of 100 TKR’s performed the same period by the same surgeon Group C: Asymptomatic TKR Group D: Symptomatic TKR performed the same period Pain Intensity rating: NRS QST Anxiety Form of the State Trait Anxiety Inventory | 1-5 yr Early-grade OA pre-op: Group A: 4.9% Group B: 5% Group C: 6% Group D: 10%. | A high percentage of patients referred for unexplained pain after TKR had early-grade OA pre-operatively |
| Noiseux et al[24] Prospective n = 215 | To discover whether any preoperative assessment could predict high pain scores and functional limitations postoperatively | Group: Pre-op. Post-op.: 6 mo Moderate to severe pain At rest: Pre-op.: 17% Post-op.: 5% With range-of-motion: Pre-op.: 52% Post-op.: 16% | Significant predictors (for moderate or severe TKR pain with knee motion after 6 mo): (1) Severe preoperative knee pain with range-of-motion; and (2) Anxiety |
| Pérez-Prieto et al[25] Prospective n = 716 Depressed: n = 200 | To evaluate quality of life, function, pain and satisfaction outcomes in patients, with and without depression, undergoing TKR | Group: Depressed patients reported significant higher pain scores than non-depressed patients pre- and post-operatively Net changes (postoperative - preoperative): No significant difference Depression leads to (1) Poorer preoperative and postoperative scores in all but the mental domains; and (2) But similar net score changes (improvement) with a high rate of patient satisfaction | | |
one assessed PPSP retrospectively in patients after both TKR and THR.9

Factors-variables related to PPSP: Multiple variables have been considered to play an important role at persistent postoperative pain. At times, different aspects of risk factors have been examined. In these studies, preoperative factors that were examined were comorbidities, preoperative pain scores20,21, and pain catastrophizing scores20,21. But only one study found to quantify the effect of sex on postoperative pain outcomes24 while another one assessed the relationship of PPSP and the Grade of knee osteoarthritis according to the scale of Kellgren and Lawrence23. Quality of life, pain and satisfaction were measured in depressed and non-depressed patients to identify differences that might exist in the scores22.

Pain scales or scores: Pain intensity mainly was measured using validated patient reported measures of pain, the most common were the Visual Analogue Scale (VAS)19,23, which is a well evaluated tool, the McGill pain questionnaire (MPQ)9,20, the Knee Society Score22,24 and the Numerical Rating Scale (NRS)21. To cover the influence of psychological factors on TKR outcomes Pain Catastrophizing Scale (PCS) was used to measure pain catastrophizing20,21, while the Two-item Patient Health Questionnaire (PHQ-2)22, Geriatric Depression Scale21,22, Medical Outcomes Study 36-Item Short Form Health, Mental Composite Score22 and Anxiety Form of the State Trait Anxiety Inventory (STAI)22 were used to measure depression and anxiety.

A recent study25 evaluated the tools that used to measure pain intensity, Knee injury and Osteoarthritis Outcome Score (KOOS) and VAS and how they affect the pain outcomes.

Pain assessment times and post-operative follow-up: At the most of the studies there was a continuous follow-up. Assessments took place preoperatively20,21,25 and postoperatively at 1 mo19,29, 3 mo19,30, 6 mo19,22,21, 12 mo20,21,22,24 and up to 1 year postoperatively19,21,22,25.

Prevalence of pain: A significant reduction of pain after TKR was observed between preoperative scores and postoperative scores; from 72% to 44%.19 A further reduction was observed up to 3 mo postoperatively where pain reached a plateau20. At 6 mo post-operatively, pain at movements was found in 16% of patients21 while pain at rest was significantly reduced in 5% of the patients.21 Others found PPSP in 18.4% of the patients at 6 mo19. PPSP has been reported at 1 year post-operatively in 13.1% of the patients29 while in another study, 44% of the patients reported to had PPSP at a mean of 4 years after TKR9. Interestingly, in one study where the same patients were tested using two different scales at one year post-operatively, the prevalence of PPSP was different; in 25% of the patients using the KOOS and in 52% using the VAS26.

Factors related to PPSP: Preoperative factors that affected pain scores were depression scores9,19, affecting both preoperative and postoperative pain scores22, early grade...
of osteoarthritis, number of comorbidities and pain problems elsewhere. Gender didn’t seemed to affect postoperative outcomes at all. A high correlation was found between preoperative pain catastrophizing scores and the existence of PPSP and its intensity. Which is in accordance with other reviews that is referred that patient’s pain catastrophizing might play an important role in chronic pain intensity.

NP after TKR (Table 2)

Studies: The existence and prevalence of NP have been reported by a small number of studies. Three prospective studies with the study population ranged from 77 to 120 patients, and 1 retrospective study with a number of 632 patients were designed for this purpose. However, other studies that aimed to evaluate specific treatments for NP recorded its prevalence too.

Pain scales or scores: Scores, initially were used to establish the existence of pain in some of these studies. These scores were Mpg, VAS and NRS.

Additionally, NP was assessed by painDetect Questionnaire (PD-Q), Leeds Assessment of Neuropathic Symptoms and Signs scale and MpQ. The contribution of depression’s and anxiety’s presence and severity to the existence of NP were examined. PHQ-2, Beck Depression Inventory (BDI), the Hospital Anxiety and Depression score and the STAI were used for this purpose.

Pain assessment times and post-operative follow-up: Pain assessment at these studies took place preoperatively, and postoperatively at 3-5 d, 6 wk, 1 mo, 3, 6 and 9 mo and up to 1 year postoperatively.

NP prevalence: A high correlation was found between VAS pain scores and NP at 3 mo, 1 year and 3 years post-op. Six weeks postoperatively a peak at the graph was observed with 27% having possible and 8% of the patients having likely NP. At 3 mo that proportion reduced to 19% with possible and 4% with likely NP.

Buvanendran et al. identified a rate of NP of 5% at 6 mo postoperatively, while in another study was found 13% of the patients having Complex Regional Pain Syndrome after TKR at both 3 and 6 mo. It is reported that at mean 4 years after TKR 6% of the patients have pain of likely neuropathic origin. The use of perioperative pregabalin reduced the incidence of NP at 0%, while placebo pregabalin didn’t seem to reduce NP.

Studies including TKR patients concerning the existence, prevalence and etiology of NP (Table 3)

Studies: A retrospective study assessed the existence and the preoperative predictors of NP in 632 TKR patients and 662 THR patients, and two prospective studies in 100 TKR patients and 89 patients after breast surgery. Another prospective study, also examined the relationship between postoperative trajectories and NP, in 112 TKR and UKR patients.

Pain scales or scores: Scores that used to assess NP were PD-Q and Diagnosing Neuropathic Pain Questionnaire, Shortform McGill Pain Questionnaire, NRS and Brief Pain Inventory were used to define the existence of pain postoperatively.

Factors studied: Preoperative factors of NP that were examined were depression, anxiety, pain catastrophizing, cognitive and emotional functioning. Depression was assessed with PHQ-2 and STAI. Spielberger STAI and PCS were used to assess anxiety and pain catastrophizing. Cognitive functioning was assessed with Trail-Making Test A + B, Rey-Osterrieth Complex Figure-copy and immediate recall, Coping Strategies Questionnaire and Brief Version of the Survey of Pain Attitudes.

Pain assessment times and post-operative follow-up: Assessments took place preoperatively, at day 1 to 8, 3 mo, 6 mo, 12 mo and 3 to 4 years postoperatively.

Factors: Acute postoperative pain, cognitive functioning, pain coping, emotional functioning and problems of pain elsewhere found to be predictors of PPSP and NP.

Prevalence: Seventy five percent of the patients seen to have NP preoperatively, according to Attal et al., 2014, while in another study NP seemed to appear on 30.7% of the patients. At 3 mo postoperatively, NP ranged between 11% and 42.2% of the patients. Six and 12 mo postoperatively patients with NP reduced at 32% and 26%, respectively. At 3 to 4 years postoperatively only 6% of TKR patients had NP.

DISCUSSION

The number of the 14 studies that used pain-specific instruments to measure pain after TKR is small and studies that approach and record NP after TKR are much less.

According to these studies, a significant proportion of patients have persistent post-operative pain for years after TKR and part of these patients suffer from pain of neuropathic origin.

Factors found to be related to persistent postoperative pain after TKR include emotional functioning such as depression and pain catastrophizing, number of comorbidities and pain problems elsewhere and operations in knees with early grade of osteoarthritis.

Nevertheless, due to the heterogeneity of the studies, mainly on the scales used to assess pain and

preoperative factors, we are unable to reach firm conclusions concerning the prevalence, and the risk factors of persistent post-operative pain after TKR. Additional studies focused on the prevalence and risk factors related to persistent postoperative pain are needed.

COMMENTS

Background

Persistent-post-surgical pain of unknown origin and neuropathic pain (NP) is considered a major underestimated problem for patients and for clinicians too.

There are several studies that measure pain with a wide variety of scores-tools.

Research frontiers

According to our acknowledgment this is the first review that analyses the prevalence of both persistent post-surgical pain (PPSP) and NP after total knee replacement (TKR), while pain is measured only with pain-specific instruments. Risk factors that might play an important role in the prediction and the prevalence of persistent postoperative pain were also analyzed.

Innovations and breakthroughs

PPSP measured by pain-specific instruments only by a few studies. From this review, it is obvious that post-surgical pain and NP exists in a significant
