ABSTRACT

BACKGROUND: Tornwaldt cyst (TC) is a relatively rare but benign disease. Although these lesions are asymptomatic and found incidentally during routine ENT examination, the can present with unexplained sinonasal symptoms, such as nasal obstruction, post nasal drip and occipital headache.

AIM: To study the clinical presentations and outcome of Tornwaldt nasopharyngeal cyst cases diagnosed and managed in our center.

METHODS: Patients with symptomatic TC who were operated and followed up at our center were selected for this study.

RESULTS: 3 patients with a diagnosis of TC by naso-endoscopy, CT and MRI were included in this study. All patients were males, with age ranging from 54 to 86 years. A trans-nasal endoscopic surgical removal of the cyst was done for all patients with no intra or post-operative complications. All patients were free of symptoms and disease reassurance at follow up.

CONCLUSION: Although relatively rare, TC should be suspected in any patient complaining of unexplained sinonasal symptoms. Endoscopic surgical excision is a safe and effective maneuver with no cyst recurrence.

1. Introduction

Tornwaldt cyst (TC) is a relatively rare but benign disease. It is a developmental lesion within the midline of the nasopharynx [1]. An incidence of 1.4–3.3% was reported by some authors in the literature [2,3].

The disease usually presents between the age of 15–30 [4,5], with the majority of cysts being undiagnosed due to their small size and benign nature. If they grow, however, they can cause a verity of symptoms that might include, nasal obstruction, postnasal drip, headache, nick stiffness and Eustachian tube dysfunction [4].

This article aims to study the clinical presentations and outcome of Tornwaldt nasopharyngeal cyst cases diagnosed and managed in our center.

2. Subjects and methods

During the period from 2014 until 2019, 3 patients with symptomatic TC who were operated and followed up at our institution were included in this study. All patients were evaluated by nasoendoscopic examination, CT/MRI scans, and pathological examination prior to surgical management. All patients were followed up post operatively to assess resolution of symptoms and disease recurrence.

Ethical clearance was obtained from the Institutional Review Board (IRB) at our institution. Written consent was obtained from all patients prior to the involvement of the study.

The research work has been reported in line with the PROCESS criteria [6].

3. Results

3.1. 3 illustrative cases

3.1.1. Case 1

An 86-year-old male patient, presented to our ENT clinic complaining of a 3 months history of left ear fullness. Other ear
symptoms, including otalgia and otorrhea were denied by the patient.
Nasoendoscopic examination revealed the presence of a well
circumscribed, smooth nasopharyngeal mass (Graph 1). Autoscopic
examination showed a dull tympanic membrane on left ear.
Audiogram revealed a left ear moderate to severe mixed hearing
loss.
CT PNS, done outside in another facility revealed soft tissue in
the nasopharynx (Graph 2).
A biopsy was taken in the clinic, histopathology report showed
multiple fragments with chronic inflammation and congested ves-
sels. No evidence of malignancy.
Complete surgical excision was done endoscopically.
The patient remained symptoms free with no signs of recurrence
at 2 years follow up.

3.1.2. Case2
A 54-year-old male patient, presented to our ENTclinic, a known
case of chronic suppurative otitis media with a surgical history of
left ventilation tube insertion, complaining of left ear hearing loss.

Naso-endoscopic examination revealed the presence of a
nasopharyngeal cystic lesion. Autoscopic examination showed
adhesive tympanic membrane type IV.
Audiogram revealed a left ear moderate conductive hearing loss.
A CT scan was done, which revealed the presence of a nasopa-
hrngeal cyst occupying the roof and posterior nasopharyngeal wall
(Graph 3).
A biopsy was taken in the clinic, histopathology report showed
benign lymphoid hyperplasia. No evidence of malignancy.
Complete surgical excision was done endoscopically.
On the one month-follow up, patient reported complete resolution
of symptoms with no evidence of recurrence of the cyst upon
examination.

3.1.3. Case3
A 55-year-old male patient, presented to our ENT clinic, com-
plaining of long term cough with excessive throat secretions.
Nasoendoscopic examination revealed the presence of an ante-
rior septal perforation with a cystic mass originating from the roof
of the nasopharynx.
An MRI and a CT scan were done. The CT scan revealed the
presence of a localized cystic nasopharyngeal mass with periph-
eral enhancement (Graph 4), while he MRI revealed the presence of
a nasopharyngeal cyst occupying the roof and posterior nasopa-
hrngeal wall (Graph 5).
A biopsy was taken in the clinic, histopathology report showed
chronic inflammation. No evidence of malignancy.
Surgical marsupialization was done endoscopically. Patient
remained symptoms free with no recurrence for 3 years.

4. Discussion
Tornwaldt cyst (TC) was first described in literature by of Dr.
Gustoff L. Tornwaldt in the 19th century as one of the causes of
pharyngeal discomfort [7]. This cyst develops as a result of defected
embryological development at the point where the notochord
retains its union with the pharyngeal ectoderm [8]. It may also be
required by means of surgical trauma, in particular nasopharyn-
gitis, chemoradiation or adenoidectomy [9,10], which has been
implicated as the etiological factor in approximately 75% of cases [11].

Tornwaldt’s cyst is mainly classified based on drainage to one of two categories, crusting and cystic. The cystic type has an obstructed drainage pathway resulting in a cyst formation, while the crusting type drains spontaneously into the nasopharynx [12].

The vast majority of these cysts are asymptomatic, and may go decades undiagnosed. If these cysts get larger in size or become infected, a variety of symptoms can manifest. These include occipital headache, seizures, dizziness/vertigo, pharyngeal discomfort, estuation tube dysfunction, pharyngitis, halitosis and post nasal drip [13–16].

Naso-endoscopic examination of the nasopharynx typically reveals a well encapsulated lesion, stationed in the posterior Middle line in the superior recess of the nasopharynx [17].

Imaging studies can be used to confirm the diagnosis, if in doubt. MRI is the gold standard modality. It is the most sensitive modality for detecting the cyst, evaluating its size, content and anatomical relationship to surrounding structures [17]. The cyst has a high signal intensity on T1-weighted, T2-weighted and fluid-attenuated inversion-recovery, with no enhancement with gadolinium contrast [18]. Computerized tomography can be used as well, with the TC appearing as a well circumscribed, low density lesion [19].

As long as the cyst is asymptomatic, not intervention is required. If symptomatic, however, the cyst can be managed surgically by means of excision or marsupialization [14]. Surgical management can lead to complete resolution of symptoms in the vast majority of patients [1].

5. Conclusion

This paper delineates the diverse clinical presentation of Tornwaldt’s cyst. The cyst can be easily diagnosed by means of nasoendoscopy or imaging studies, supported by histopathological examination. Long term follow up for our patients have proven the effectiveness and safety of endoscopic surgical excision with no recurrence detected up to 3 years post operatively. Although relatively rare, TC should be suspected in any patient complaining of such symptoms and be managed accordingly.

Declaration of Competing Interest

The authors declare that there is no conflict of interest regarding the publication of this paper.

Funding

There is no financial support and sponsorship.

Ethical approval

This research has been approved by the IRB committee at KFSH Dammam.

Consent

Written informed consent was obtained from all patients for publication of this case series.
Author’s contribution

ZAINAB ALSHUHAYB: conceptualization, validation, data curation, writing - original draft. Writing.
