Abstract

**Background and aims:** To explore the relationship between serum cystatin C and sudomotor function produced by the SUDOSCAN in subjects with type 2 diabetes mellitus.

**Methods:** The research incorporated 917 Chinese individuals with type 2 diabetes mellitus from May 2017 to May 2019. All patients underwent SUDOSCAN and examined cystatin C. SUDOSCAN was evaluated with electrochemical skin conductance in hands (HESC) and feet (FESC), asymmetry ratio in hands (HASYM) and feet (FASYM). Average FESC <60 µS was defined as sudomotor dysfunction. 917 patients were classified into 791 diabetic patients without sudomotor dysfunction, and 126 diabetic patients complicated with sudomotor dysfunction. The difference of cystatin C between two groups was compared firstly, the difference of SUDOSCAN metrics among tertiles of serum cystatin C was also compared. The spearman and multiple linear regression analyses were applied to analyze the association between serum cystatin C and SUDOSCAN metrics.

**Results:** The total prevalence of sudomotor dysfunction was 13.74%. Patients with sudomotor dysfunction had a higher level of cystatin C ($P<0.001$). With increasing tertiles of serum cystatin C, ESC declined, ASYM elevated, and the prevalence of sudomotor dysfunction increased ($P<0.001$). The spearman analysis performed an association between serum cystatin C and SUDOSCAN metrics including HESC ($r=-0.143$, $P<0.001$), FESC ($r=-0.178$, $P<0.001$), HASYM ($r=0.169$, $P<0.001$), FASYM ($r=0.174$, $P<0.001$). Multivariate regression linear analyses demonstrated cystatin C was independently linked with HESC ($B=-14.657$, $P<0.001$) and FESC ($B=-10.015$, $P=0.022$) levels after controlling for potential confounders.

**Conclusions:** Serum cystatin C is inversely linked with sudomotor function detected by SUDOSCAN in Chinese patients with type 2 diabetes mellitus.

Introduction

Diabetic peripheral neuropathy (DPN) is the most common diabetic complications, which makes serious damage to the nerves in our arms, hands, legs, and feet. Previous study revealed that more than half of people with diabetes were complicated with DPN [1]. Distal symmetric polyneuropathy (DSPN) is one of the most shared types of DPN, which characterized by chronic, symmetrical, prolonged length and sensorimotor polyneuropathy [2]. DSPN is a significant risk element for diabetic foot, so it can greatly increase the mortality and disability of subjects with type 2 diabetes mellitus (T2DM) [3]. It often affects distal diminutive nerve fibers and manifests as aching neuropathy, however, upon most occasions, symptoms of DSPN are insidious, up to 50% of patients without evident symptoms in the early stage of DSPN, symptoms are severe when they are diagnosed [4]. At present, the most trustworthy diagnosis of DPN is the biopsy, but it is difficult to carry out on a large scale because it is an invasive operation [5].

SUDOSCAN (Impeto Medical, Paris, France) is a new screening technique for the detection of DSPN through assessment of sweat gland sudomotor function as a reflection of early peripheral small fiber
neuropathy impairment [6]. As a simple and impersonal screening technique for DSPN, SUDOSCAN has been popular in Caucasian and Indian people [7]. The measurement of sudomotor function including electrochemical skin conductance (ESC, measured in µS). And the basic principle of detecting ESC is reaction between sweat chlorides and electrodes. Results are presented as HESC, FESC, symmetry ratio in hands (HASYM) and feet (FASYM) [8]. Sudomotor dysfunction can be detected by SUDOSCAN in the inchoate stage of DSPN. Compared with other detection methods, the ESC detection is more sensitive, hence more and more doctors are prone to use it for the inchoate diagnosis of DPN [9].

Cystatin C (Cys-C), as a small molecular substance, is an endogenous cysteine protease inhibitor. It has been used as a sensitive metric to evaluate renal function because of free filtration in glomeruli [10]. In the last few decades, some researchers have found serum Cys-C level was positively associated with the mortality of cardiovascular and cerebrovascular diseases like coronary heart disease, peripheral arterial disease, stroke and so on, which explains its roles beyond information about renal function [11]. In addition, serum Cys-C level was positively linked with the prevalence of central and peripheral neuropathy in T2DM [12, 13].

However, the link between serum Cys-C and sudomotor function was not explored clearly yet. In this study, we aim to explore the correlation between serum Cys-C and sudomotor function assessed by SUDOSCAN in Chinese subjects with T2DM.

**Methods**

**Participants**

The research enrolled 917 T2DM inpatients at the endocrinology department of the General Hospital of Eastern Theater Command from May 2017 to May 2019. The whole of them conformed to the 1999 WHO diagnostic criteria for diabetes [14]. Exclusion criteria included: 1. Individuals with severe illness or acute stress such as heart failure, liver failure, acute or chronic inflammatory disorders, malignant disease and surgery. 2. Subjects with abnormal renal function (eGFR < 60 ml/min/1.73 m2). 3. Subjects who had a history of using oral medications that may affect the nervous system. 4. Subjects with the rest of metabolic disorder like the lack of vitamin B12. The research was supported by the local ethics committee.

**Anthropometric indices and laboratory examination**

Medical history including age, gender, diabetes duration, height, weight, smoking was gained through medical records. Systolic blood pressure (SBP), diastolic blood pressure (DBP) were measured, body mass index (BMI) was calculated. Blood and urine samples were gathered overnight fasting for hemoglobin A1C (HbA1c), uric acid (UA), total bilirubin (T-BIL), direct bilirubin, (D-BIL), triglyceride (TG), total cholesterol (TC), high density lipoprotein (HDL), low density lipoprotein (LDL), fasting blood glucose (FBG), 2-hour postprandial blood glucose (PBG), serum urea nitrogen (BUN), cystatin C (Cys-C), free fat acid (FFA), homocysteine (Hcy) and serum creatinine (Scr). eGFR was counted using Chronic Kidney
Disease- Epidemiology Collaboration (CKD-EPI) equation [15]. Serum Cys-C level was measured by immunoturbidimetry.

**SUDOSCAN test**

SUDOSCAN (Impeto Medical, Paris, France) as a quick, nonintrusive and quantitative device, was applied to assess sudomotor function on the basis of sweat chloride concentrations. The appliance had two parts of electrodes which are connected to a computer. Patients placed their limbs on the electrodes only about two or three minutes and an incremental low voltage (< 4 V) was applied to the electrodes automatically. Quantification data were showed as HESC, FESC, HASYM and FASYM. Sudomotor dysfunction refers to average FESC is < 60 µS. 917 patients were classified into 791 diabetic patients without sudomotor dysfunction, and 126 diabetic patients complicated with sudomotor dysfunction. The operation is painless, rapid and no specific preparation is needed. What's more, the quantitative results are unaffected by room temperature [16].

**Statistical analysis**

SPSS 22.0 software was applied for statistical analyses. All data were presented as the mean ± standard deviation (SD), median (upper and lower quartiles) or proportions according to different data types. For continuous variables, Student's t-test was used to compare two groups, and one way ANOVA was applied to contrast more than two samples. Wilcoxon rank-sum test was applied for abnormal distributions. Chi-square test was used for categorical variables. Spearman's rank correlation was performed to evaluate the association of serum Cys-C and SUDOSCAN metrics. And multiple linear regression analysis was carried out to explore the link between serum Cys-C and SUDOSCAN metrics after adjusting for age, diabetes duration, Cys-C, SBP, DBP, BMI, HbA1C, TC, HDL, FFA, Scr and eGFR. $P < 0.05$ was considered statistically significant.

**Results**

*Clinical characteristics of individuals with and without sudomotor dysfunction.*

The whole of baseline information was shown in Table 1. The mean age of all participants was 54.76±12.42 years, and the median duration of diabetes was 7 (2, 11) years. The total prevalence of sudomotor dysfunction was 13.74%. Compared without sudomotor dysfunction group, patients with sudomotor dysfunction were older and had a longer duration of diabetes ($P<0.001$). Besides, patients with sudomotor dysfunction showed increased levels of BUN, UA and Cys-C, and lower levels of eGFR and FFA ($P<0.05$).

*Clinical characteristics and SUDOSCAN parameters of subjects among tertiles (T1-T3) of serum Cys-C level.*

Farther statistics after dividing participants into groups on the basis of tertiles for serum Cys-C level. Table 2 showed the following points. First of all, participants with the highest tertiles of serum Cys-C were
older and had a longer duration of diabetes ($P<0.001$). What’s more, patients with the highest tertiles of serum Cys-C had higher SBP, BUN, SCr, UA and Hcy, lower eGFR, TC, FBG and HbA1C ($P<0.05$). Of note, patients with the highest tertiles of serum Cys-C had higher HASYM, FASYM and lower hand ESC, foot ESC ($P<0.001$).

**Prevalence of sudomotor dysfunction in different tertiles of serum Cys-C level.**

Patients were divided into three groups according to the tertiles of serum Cys-C level, the prevalence of sudomotor dysfunction increased with the increase of Cys-C. ($P<0.001$) (Figure 1).

**The association between clinical characteristics and metrics of SUDOSCAN.**

The association between serum Cys-C and metrics of SUDOSCAN was constructed with Spearman’s rank correlation analysis. Serum Cys-C level negatively associated with hand and foot ESC ($P<0.001$). What’s more, serum Cys-C level positively associated with HASYM and FASYM ($P<0.001$). Age, diabetes duration and SBP inversely associated with hand and foot ESC, positively associated with HASYM and FASYM ($P<0.05$). eGFR positively associated with hand and foot ESC, inversely associated with HASYM and FASYM ($P<0.05$). BMI only positively correlated with hand ESC ($P<0.05$). Of note, there was no relationship between HbA1C and parameters of SUDOSCAN. (Table 3)

**Multivariate regression linear analyses of association between serum Cys-C and parameters of SUDOSCAN.**

Multivariate regression linear analyses were adjusted for age, diabetes duration, Cys-C, SBP, DBP, BMI, HbA1C, TC, HDL, FFA, Scr and eGFR. The data demonstrated cystatin C was independently linked with HESC and FESC levels. But the link was disappeared for HASYM or FASYM. Besides, for FESC, the older age and the longer diabetes duration were risk factors, the higher BMI, HDL and eGFR were protected factors. For HASYM, elevated SBP was a dangerous factor, rather DBP was a protect factor. Finally, for FASYM, elevated BMI and TC were protect factors. (Table 4)

**Discussion**

Overall, our study revealed serum Cys-C inversely associated with sudomotor function, which detected by SUDOSCAN. Patients with sudomotor dysfunction had a higher level of cystatin C ($P<0.001$). With increasing tertiles of serum cystatin C, ESC declined, ASYM elevated, and the prevalence of sudomotor dysfunction increased ($P<0.001$).

As one of the most vital risk factors for diabetic foot, DSPN can greatly increase the mortality and disability of individuals with T2DM [3]. The main manifestation of DSPN is the destruction of small unmyelinated sympathetic nerve fibers, so it is difficult to detect early DSPN. The traditional and common methods to explore small fiber neuropathies including skin biopsy, quantitative sudomotor axon reflex test (QSART) and neuropad [2]. The most trustworthy diagnosis of DPN is the biopsy, but it is difficult to carry out on a large scale, because it is an invasive operation [17]. QSART is a recommended method, but
it takes more time. Also, neuropad is not a quantitative test, and it has low sensitivity and specificity [2]. ESC measurement detecting by SUSOSCAN is an emerging method in recent years [18]. American Association of Clinical Endocrinologists (AACE) guidelines in 2015 mentioned sudomotor function can be applied to assess early neuropathy [19]. Sudomotor function test can be used in a wide range because it is fast, impersonal quantitative and not complicated.

Previous studies found longer diabetes duration, older age, higher HbA1c levels had a dangerous effect on the incidence of DPN [20]. Consistent with these, our study also found age and diabetes duration were negatively associated with FESC. But there was no relationship between HbA1c and any metrics of SUSOSCAN, we speculated that glycemic variability may play a greater role in the sudomotor dysfunction, exactly as a recent study demonstrated glycemic variability metric like time in range play a greater role in the prevalence of diabetic cardiovascular autonomic neuropathy [21]. What’s more, as small sympathetic unmyelinated C-fibers innervate sweat glands, we found SBP negatively associated with ESC, positively correlated with HASYM and FASYM. So the older people who are easy to suffer from a higher level of SBP, should pay more attention to the examination of Cys-C level and sudomotor function. Finally, a mild relationship between BMI and sudomotor dysfunction was found. However, most researchers have found BMI had a dangerous effect on DPN. However, Xu et al hold a diverse view: lower BMI might be a latent risk factor for DPN [22]. Also, a new research from China in which they reported that lower BMI had a dangerous effect on diabetic complications [23]. In the multivariate regression linear analyses, we also found TC was negative with HASYM and FASYM, this is probably because lower TC may indicated that nutrition in patients with DPN was imbalance, which may negatively affected the rehabilitation of DPN [22].

Cys-C, as a sensitive metric to evaluate renal function because of free filtration in glomeruli, may provide more information about diabetes mellitus beyond renal function [24]. In the last few decades, some researchers have found positive associations between serum Cys-C level and the risk for T2DM [25]. Qian et al confirmed the level of serum Cys-C was positively linked with retinopathy in characters of T2DM [26]. Qamar et al found that serum Cys-C level could be applied as an inchoate evaluation for the renal dysfunction in T2DM individuals with normal urine protein [27]. Zhao et al demonstrated serum CysC linked with a high prevalence of diabetic foot ulceration in T2DM [28]. Also, there were studies research the link between Cys-C and diabetic neuropathy. One study found serum Cys-C level was positively linked with cardiovascular autonomic neuropathy in subjects with T2DM [29]. Hu et al demonstrated high Cys-C concentration was closely linked with DPN and the cutoff value of serum Cys-C indicating DPN was 1.25mg/L in men and 1.05 mg/L in women [30]. Different researchers have also proven that Cys-C has a significant effect on central and peripheral nervous diseases [31-32]. In the central nervous system, Cys-C functioned as an endogenous cysteine protease inhibitor. It has been testified Cys-C plays a regulatory role on agglomeration and sedimentation of amyloid [33]. Compared to normal people, subjects had higher serum Cys-C, who suffered from mild cognitive impairment, Alzheimer's or Parkinson's [34-36]. In addition, the CysC level in cerebrospinal fluid varied significantly in demyelinating diseases such as Guillain Barre Syndrome [37]. Nagai et al also demonstrated Cys-C was linked with the apoptosis of
neurons [38]. Consistent with these studies, our study showed a robust link between serum Cys-C level and sudomotor dysfunction in Chinese T2DM. Subjects with sudomotor dysfunction had a higher level of cystatin C. With increasing tertiles of serum cystatin C, ESC declined, ASYM elevated, and the prevalence of sudomotor dysfunction increased. More importantly, serum Cys-C inversely linked with sudomotor function like FESC and HESC. Serum Cys-C level was bound up with eGFR, and there was a higher level of eGFR in individuals complicated sudomotor dysfunction, eGFR positively linked with ESC and inversely linked with ASYM. Nevertheless, after adjusting for age, diabetes duration, Cys-C, SBP, DBP, BMI, HbA1C, TC, HDL, FFA, Scr, the relationship between eGFR and HESC disappeared.

At present, the destructive mechanism between serum Cys-C and sudomotor dysfunction is not fully clarified, which may include the following points. Cys-C may participate in the pathological process of diabetic microvascular complications through inflammation, oxidative stress, degradation of extracellular matrix and vascular remodeling [39]. Cys-C and its degradation products can activate neutrophils, thus mediating inflammatory response, and increasing the concentration of C-reactive protein. A high concentration of C-reactive protein can lead to dysfunction of vascular endothelial or destruction of endothelial cells directly [40]. Besides, Cys-C can inhibit homocysteine catabolase, the high level of homocysteine can lead to oxidative stress, destruction of vascular endothelial cells [41].

Serum Cys-C measurement is simple and routine, and is highly accessible in every community hospital. Therefore, serum Cys-C level can be applied easily as one of the risk factors for sudomotor dysfunction. Careful consideration of SUDOSCAN screening is needed when managing subjects with T2DM and a high level of serum Cys-C concentration.

Nevertheless, our study has a few limitations. First of all, our study only enrolled individuals with T2DM, so it was not possible to explore the relationship between other types of diabetes and sudomotor function. Secondly, this was a cross-sectional study, so it was impossible to explore the causality between serum Cys-C and sudomotor dysfunction.

**Conclusion**

In conclusion, our data showed that serum Cys-C inversely linked with sudomotor function like FESC and HESC, which were detected by SUDOSCAN. Besides, serum Cys-C level positively associated with HASYM and FASYM. Further prospective research is needed to identify the risk role of serum Cys-C for sudomotor dysfunction in subjects with T2DM.

a SBP, systolic blood pressure, DBP, diastolic blood pressure, T-BIL, total bilirubin, D-BIL, direct bilirubin, BUN, blood urea nitrogen, SCr, serum creatinine, eGFR, estimated glomerular filtration rate, UA, uric acid, Cys-C, cystatin C, TC, total cholesterol, TG, triglyceride, HDL, high density lipoprotein, LDL, low density lipoprotein.
lipoprotein, Hcy, homocysteine, FFA, free fat acid, FBG, fasting blood glucose, PBG, postprandial blood glucose, HbA1C, hemoglobin A\textsubscript{1}C, BMI, body mass index.

Normally distributed values in the table are presented as the means ± SD, non-normally distributed values are presented as medians (25% and 75% interquartiles) and categorical variables are presented as frequencies (percentages). Student's t-test for comparison of two samples with a normal distribution, Wilcoxon rank-sum test for abnormal distributions.X2-test for categorical variables.

Table 2 Clinical characteristics and SUDOSCAN parameters of individuals among tertiles (T1-T3) of serum Cys-C level.
|                           | T1 (<0.92 mg/L) | T2 (0.92-1.12 mg/L) | T3 (>1.12 mg/L) | x2/F/z | P   |
