A B S T R A C T

The bamboo treatment process starts with cutting, soaking in water, draining in free air, reinforcing in the fireplace, first-stage adhesive coating, hose-clamp installation, second-stage adhesive coating, and sand resurfacing. Data was taken from experimental testing of bamboo materials and bond strength tests of bamboo reinforcement in the laboratory of the Faculty of Engineering, University of Brawijaya Malang. The aim of treating and strengthening bamboo reinforcement is to overcome low-load capacity and prevent collapse due to slippage in bamboo reinforced concrete elements. Adhesive coating is employed to increase durability and prevent water absorption, while installing hose-clamps increases bamboo reinforcement slip resistance. The process outlined here represents the way to approach bamboo reinforcement, and laboratory data is processed into graphic images and tables of bond strength of bamboo reinforcement providing the basis for further research. This article comprises a standard operating procedure for treatment of bamboo reinforcement, graphic images, documentation photos, and data tables. The data is related to "Enhancing bamboo reinforcement using a hose-clamp to increase bond-stress and slip resistance" [1].

1. Data

In this article, data is presented in the form of the standard operating procedure (SOP) for bamboo reinforcement treatment, graphic images, documentation photos, and data tables. Standard operating procedure (SOP) of bamboo reinforcement treatment starts with cutting, soaking in water, draining in free air, reinforcing in the first-stage adhesive coating, hose-clamp installation, second-stage adhesive coating, and sand resurfacing as shown in Figs. 4–11.

Raw data of bond stresses and failure patterns in bamboo reinforcement pull-out tests of seven treatments are presented in Table 1, while analysis data in the form of a graph of the relationship between bond stress and variations in bamboo reinforcement treatment is shown in Fig. 1. A data graph of the load-deflection relationship of a bamboo reinforced concrete beam, with LVDT readings from after the collapse of the beam, is shown in Fig. 2. The raw data from Fig. 2 is provided in the following link: http://bit.ly/2PvYuXS. Fig. 3 shows the load-deflection relationship of bamboo reinforced concrete beams compared to results from previous researchers. The raw data from Fig. 3 is shown in the following link: http://bit.ly/2NxiYgq.

2. Experimental design, materials, and methods

Bamboo petung (Dendrocalamus asper), features purplish black bamboo shoots, covered with feathers (miang) which resemble brown to black velvet. The large vertebrae are 40–50 cm long, and 12–18 cm in diameter. Overall, petung bamboo reaches 20 m in height, with a curved tip, with color

Fig. 3. The load-deflection relationship of BRC beams compared to previous research results [2].
varying from green, dark green, purplish green, whitish green, or with white spots because of lichen. The nodes are surrounded by aerial roots. The thickness of the bamboo wall is between 11 and 36mm (Brink, M, 2008) in Wikipedia Indonesia [3].

Standard operating procedure (SOP) for preparing bamboo reinforcement includes installing hose-clamps, waterproof coating, sand coating, pull-out test setting, and flexural test setting.

Step 1: Bamboo cutting.

The bamboo used was at least three years old, with white spots, as shown in Fig. 4. Bamboo stems used are 6 m long from their base. This is because stems exhibit stronger mechanical properties and thickness up to 6 m. After logging, bamboo is cut to the size planned, and soaked in water for more than

a month. Bamboo reinforcement pieces are cut to a length of approximately $1100 \times 15\text{mm}$. The number of nodes varies between two and three pieces.

Step 2: Drying of bamboo in free air for $\pm 1$ month [1,2,4] after soaking in water, as shown in Fig. 5.

Step 3: Fireplace treatment and adjustment of dimensions, as shown in Fig. 6.

Step 4: Fireplace and treating the surface of the bamboo reinforcement with a grinding machine, as shown in Fig. 7.

Step 5: Preparation of materials and tools, including, Sikadur®-752, fine sand, hose-clamps, and brushing, as shown in Fig. 8.

Step 6: The initial coating of adhesive Sikadur®-752, and installation of hose-clamps on the bamboo reinforcement, as shown in Figs. 9 and 10.

Instructions for installing hose-clamps:

- The initial stage of Sikadur®-752 adhesive surfacing is carried out after the fireplace treatment, based on the planned dimensions.
- Sikadur®-752 surfacing is carried out until it is even.
- Installation of hose-clamps is carried out after the first Sikadur®-752 layer is dry.
- The hose-clamps are installed in two ways, namely (1) by loosening the nut-bolts of the hose-clamps and directly inserting from the end of the bamboo reinforcement, or (2) opening the hose-clamps and installing them at the point of the installation plan.
- Hose-clamps are tightened with a screwdriver, turned until it stops. There should be no additional tightening, so as to avoid defects and waterproof coating leaks on the bamboo reinforcement.
- After the clamps are installed, a second Sikadur®-752 surfacing is carried out.
- The coating of sand on bamboo reinforcement is applied after the second layer of Sikadur®-752 adhesive is half dry, as shown in Fig. 11.
