A hypoxic environment is thought to be important for the maintenance of stemness and suppressing cell senescence, in stem cells. Therefore, a hypoxic condition is induced during cell expansion and/or induction of intended differentiation. However, the induction of these conditions requires a specially equipped hypoxia chamber and expensive gas mixtures, which are expensive and space-consuming. Owing to these restrictions, appropriate hypoxic conditions cannot be provided during cell transportation, which is increasingly required for regenerative medicine. Hence, a simple and economical culture system is required. The purpose of this study was to investigate the effects of short-term hypoxic conditions on human mesenchymal stem cell (MSC) proliferation, viability, and senescence, utilizing the CulturePal system (CulturePal-Zero and CulturePal-Five), a novel and simple hypoxic culture system with a built-in deoxidizing agent. The \(O_2\) concentration in the CulturePal-Zero was observed to reduce to \(<0.1\%\) within 1 h, and to 5\% within 24h in the CulturePal-Five system. Cell proliferation under these hypoxic conditions showed a sharp increase at 5\% \(O_2\) concentration, and no noticeable cell death was observed even at severe hypoxic conditions (\(<0.1\%\) \(O_2\)) up to 72h. The \(p_{16}^{\text{INK4A}}\) (cell senescence marker) mRNA expression was retained under hypoxic conditions up to 72h, but it was up-regulated under normoxic conditions. Interestingly, the \(p_{16}^{\text{INK4A}}\) expression altered proportionately to the \(O_2\) concentration. These results indicated that the short-term hypoxic condition, at an approximate \(O_2\) concentration of 5\%, would be suitable for promoting cell proliferation and repressing cell senescence, without aggravating the MSC viability. Therefore, the CulturePal systems may be suitable for providing an appropriate hypoxic condition in stem cell research and transportation.

**Introduction**

Under *in vivo* conditions, stem cells exist in a hypoxic environment, which is thought to be an important factor for the maintenance of its phenotype\(^1\). In addition, *in vitro* cell culture exposed to normoxia is subjected to oxidative stress, and causes cell senescence\(^2\). Therefore, to maintain stemness and avoid oxidative stress, the use of a hypoxic culture, resembling *in vivo* environments, has been recommended\(^3\)\(^4\).

Mesenchymal stem cells (MSCs) are somatic stem cells, and are promising candidates for applications in cell therapies due to their multipotency and immunotolerance\(^5\)\(^6\). Hypoxic conditions have been previously reported to promote MSC proliferation\(^7\)\(^8\), maintain the undifferentiated state of the cell\(^9\)\(^11\), and induce differentiated state when cultivated under differentiative culture conditions\(^9\). In addition, hypoxic conditions have been shown to suppress cell senescence\(^8\)\(^12\). However, there have been contrasting reports stating that the hypoxic conditions exert little effect on cell proliferation or induction of differentiation\(^11\)\(^13\)\(^14\). Therefore, the effect of hypoxia on MSCs remains controversial, necessitating further research. However, it is clear that the regulation of gas concentrations, such as that of oxygen (\(O_2\)) and carbon dioxide (\(CO_2\)), is an essential parameter for the modulation of cell phenotype and metabolism.

In general, hypoxic conditions are induced by exchanging atmospheric air with a gas mixture (95\% \(N_2\)/5\% \(CO_2\)) within a specially equipped hypoxia chamber. However, such equipment is expensive and requires a lot of space, when several gas concentrations and/or other conditions are investigated simultaneously.

With the development in regenerative medicine there has arisen an increasing need for an effective cell transportation protocol, in order to deliver manufactured cells such as stem cells and primary cells to patients. Although the use of
appropriate gas conditions are considered important to maintain or improve cell quality, its regulation is quite cumbersome because it requires the use of complicated equipment. Therefore, the control of cell quality by the regulation of gas conditions during transportation is still a difficult process.

To overcome these issues, a simple culture system that does not require gas incubators and gas cylinders must be developed. The AnaeroPack (Mitsubishi Gas Chemical Company Inc., Tokyo, Japan) and the AnaeroGen (Oxoid, Basingstoke, United Kingdom) systems are currently being applied for the simple cultivation of anaerobes \cite{13}, or to induce hypoxic injury in mammalian cells \cite{16, 17}. However, these systems have been unable to control and modulate the O₂ concentration in mammalian cell cultivations, although some methods have been reported where the AnaeroPack system has been applied for the induction of hypoxic conditions \cite{18, 19}. The CulturePal system (Trial Products; Mitsubishi Gas Chemical Company Inc.) is a novel gas concentration regulating reagent for the induction of a hypoxic atmosphere. This reagent contains sodium ascorbate as the principal constituent, which absorbs O₂ and generates CO₂ by oxidative degradation, as well as a CO₂ absorber to control the CO₂ levels. Two series of the CulturePal system have been developed—the CulturePal-Zero and CulturePal-Five. CulturePal-Zero is designed to modulate the O₂ and CO₂ concentration levels to <0.1% and 3–7%, while the CulturePal-Five regulates the concentration to 3–7% and 3–7%, respectively. We hypothesized that the CulturePal systems would be a suitable and simple system providing short-term hypoxic conditions, and for the regulation of gas concentrations during cell transportation. However, the capacity of this system to induce hypoxic responses, replicating the results obtained in a conventional gas atmosphere-controlling chamber, remains to be tested.

Therefore, the purpose of this study was to investigate the effects of short-term hypoxic conditions induced by the CulturePal hypoxic culture system with a built-in deoxidizing agent, on MSC proliferation, viability, and senescence.

**Materials and methods**

**Induction of hypoxic conditions and measurement of O₂ and CO₂ concentrations**

The general procedure for use of the CulturePal system is as demonstrated in Figure 1. The foil package was opened (Figure 1A), the reagent placed in an air-tight jar containing the culture (Figure 1B), and the lid closed immediately (Figure 1C).

The reagent is activated upon contact with air, and the hypoxia is initiated (Figure 1D). In order to assess the time-lapse changes in O₂ and CO₂ concentration under hypoxia conditions induced by the CulturePal-Zero and CulturePal-Five systems, the reagents were placed in a 2.5-L airtight jar (Mitsubishi Gas Chemical Company Inc.) each. The O₂ and CO₂ concentrations were measured at 1, 4, 24, 72, and 168h after induction of hypoxia using a CheckMate II (PBI-Dansensor A/S, Ringsted, Denmark). The experiments were repeated four times.

**Cell culture and hypoxic exposure**

Human MSCs derived from the bone marrow were purchased from PromoCell (C-12974; Heidelberg, Germany) and expanded in MEM alpha + GlutaMAX medium (Gibco [Life Technologies], Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (HyClone [Thermo Fisher Scientific], Waltham, MA, USA), 50 U/mL penicillin and 50 μg/mL streptomycin (Nacalai Tesque Inc., Kyoto, Japan). The culture was incubated in a CO₂ incubator (95% air atmosphere, 5% CO₂, 37°C, and 95% humidity: defined normoxia) up to the third or fourth passage. The medium was changed at 3-day intervals. Following the third/fourth passage, the culture plates or dishes were placed in a 2.5-L airtight jar with CulturePal-Zero, CulturePal-Five (hypoxia), or without the CulturePal reagent (normoxia). The lid of the airtight jar was closed immediately, except for that of the normoxia sample. These jars were placed in the CO₂ incubator and incubated for 24 or 72h. The cell cultures in some of the culture dish samples were observed under a phase-contrast microscope (OLYMPUS, Tokyo, Japan) in order to observe the morphological changes in the cell.

**Cell proliferation under differing O₂ concentrations**

The MSCs were harvested from the culture dishes using phosphate buffer saline (PBS) with 0.25% trypsin and 0.02% ethylene diamine tetraacetic acid (EDTA). These were then re-seeded on 96-well culture plates at a density of 5.0 × 10⁴ cells/well (n = 15 wells/group). The cells were pre-cultured in normoxia for 20h. Subsequently, the culture plates were exposed to hypoxia for 24 or 72h using the procedure described in the previous section. The cell count was quantified using the cell counting kit-8 (Dojindo Molecular Technologies, Rockville, USA), according to manufacturer’s instructions. Briefly, 10 μL of the cell counting kit-8 solution was added to each well, and the plate included for 2h in the CO₂ incubator. The absorbance was measured at 450 nm using a microplate reader (Multiskan FC Microplate Photometer; Thermo Fisher Scientific).

---

Figure 1. Use of the CulturePal system for hypoxia cell culture
(A) The foil package was opened, and (B) placed in the airtight jar containing the culture medium. (C) The lid was then closed immediately. (D) The hypoxia was initiated in this culture system.
Cell viability at varying $O_2$ concentrations

The MSCs were re-seeded on 35 mm glass-bottom culture dishes (CELLview Glass Bottom Dish; Greiner Bio-One Co. Ltd., Tokyo, Japan) at a seeding density of $1.0 \times 10^5$ cells/well, and pre-cultured at normoxia for 20h. Subsequently, the culture dishes were exposed to hypoxia conditions using the procedure described in the previous section. Cell viability was assessed using a LIVE/DEAD Viability/Cytotoxicity Assay Kit (Life Technologies), as per the manufacturer’s instructions, 24 or 72h after induction of hypoxia. Briefly, the cells were washed twice with PBS, and treated with 0.5 µM of calcein AM and 4µM of ethidium homodimer-1 (EthD-1) for 30 min at room temperature. The live cells, labeled with calcein AM, produce a green fluorescence, whereas the dead cells, labeled with EthD-1, fluoresce a red color. The labeled cells were observed under a fluorescence microscope (FluoView FV10i; OLYMPUS), and the live (green) and dead (red) cells from 16 views (1272.8 µm x 1272.8 µm/view) were counted from four wells per group. Cell viability was calculated as the proportion of the number of the live cells to the total number of cells counted.

Utilizing $p16^{INK4A}$ mRNA expression at varying $O_2$ concentrations as a cell senescence marker

The MSCs were re-seeded on 60 mm culture dishes at a density of $3.0 \times 10^5$ cells/well ($n = 3$ wells/group), and pre-cultured in normoxia conditions for 2 days. Subsequently, the culture dishes were exposed to hypoxia using the procedure detailed in the previous section. At 24 or 72h after induction of hypoxia, the total RNA was extracted using the RNeasy Mini Kit, according to the manufacturer’s protocol (Qiagen, Limburg, Netherlands). The purity of the extracted RNA was tested using the NanoDrop2000 (Thermo Fisher Scientific). The total RNA (1 µg) was reverse-transcribed to synthesize cDNA. A real-time quantitative polymerase chain reaction (qRT-PCR) was performed on the Applied Biosystems 7500 Real-Time PCR System (Life Technologies) using the commercially available, TaqMan gene expression assays (Life Technologies): the $p16^{INK4A}$ (Hs00923894_m1), and eukaryotic 18S rRNA (18S: Hs03003631_g1). Standardized enzyme and cycling conditions developed for the 7500 Real-Time PCR System were used for PCR cycling. 18S was used as the control housekeeping gene. Template cDNA, corresponding to 10 ng of RNA, was added to each PCR reaction mix, and all biological samples were run in technical duplicates, for each gene. The data obtained by qRT-PCR was analyzed by the comparative threshold cycle method. Briefly, the quantity of $p16^{INK4A}$ was normalized to that of 18S, the value of the calibration sample (the cells cultured in normoxia for 24h) was set to 1, and the values for each of the other conditions were determined relative to that of the calibration sample.

Statistical analysis

All values are presented as mean ± standard deviation. Statistical significance was determined by one-way analysis of variance, with the post-hoc multiple comparison Tukey-Kramer test. The differences observed were considered significant if the $p$ value was less than 0.05.
Table 1. Mean and standard deviations of O$_2$ and CO$_2$ concentrations in the hypoxial culture jars

| %     | Time | 1h   | 4h   | 24h  | 72h  | 168h |
|-------|------|------|------|------|------|------|
|       |      |      |      |      |      |      |
| CulturePal-Zero | | | | | | |
| O$_2$ | 0.02 ± 0.005 | <0.10 | <0.10 | <0.10 | <0.10 |
| CO$_2$| 3.90 ± 0.141 | 4.00 ± 0.141 | 3.45 ± 0.100 | 3.35 ± 0.100 | 3.35 ± 0.100 |
| CulturePal-Five | | | | | | |
| O$_2$ | 7.55 ± 0.238 | 6.43 ± 0.206 | 5.01 ± 0.155 | 4.53 ± 0.222 | 4.41 ± 0.248 |
| CO$_2$| 4.75 ± 0.173 | 5.23 ± 0.095 | 4.35 ± 0.191 | 3.38 ± 0.206 | 2.38 ± 0.206 |

Morphological changes in the cells at varying O$_2$ concentrations

The MSCs displayed a fibroblast-like morphology at all conditions, 24h after the induction of hypoxia (Figure 3). On the other hand, 72h after hypoxia induction, the MSCs exposed to <0.1% O$_2$ displayed morphological alterations such as a rounded shape. No apparent morphological changes were seen in the cells maintained in 21% O$_2$ and 5% O$_2$ conditions (Figure 3).

Cell proliferation at different O$_2$ concentrations

No significant differences were observed in the cell proliferation pattern between the groups, 24h after hypoxia induction (Figure 4). The MSC cell count increased in all groups at 72h. A comparison of cell counts between the groups at 72h revealed that 5% and <0.1% O$_2$ conditions resulted in the highest and lowest cell counts, respectively (Figure 4).

Cell viability at varying O$_2$ concentrations

The cell morphology was visualized by calcein AM staining (green). We observed a shrunken shape in the cells incubated at <0.1% O$_2$ conditions, 72h after the induction of hypoxia (Figure 5A). However, the cell viability at 24 and 72h was observed to be very high (over 94%) even under <0.1% O$_2$ conditions. However, cells cultured at <0.1% O$_2$ conditions were slightly, but significantly less viable than those cultured in 21% O$_2$, 72h post-induction (p < 0.05, Figure 5B).

p16$^{INK4A}$ mRNA expression at different O$_2$ concentrations

At 24h after the induction of hypoxia, p16$^{INK4A}$ mRNA expression was observed to be significantly down-regulated in <0.1% O$_2$, compared to 21% O$_2$ and 5% O$_2$ culture.
The effect of hypoxia on mesenchymal stem cells using a simple culture system

Discussion

In this study, we employed the CulturePal trial reagents for the simple induction of hypoxic conditions, and investigated the time-lapse changes in O₂ and CO₂ concentrations in the systems. Furthermore, we also investigated the effects of short-term hypoxia on human MSC proliferation, viability, and p16INK4A mRNA expression, by utilizing the CulturePal systems. The CulturePal-Zero was able to induce severe hypoxia (<0.1% O₂) within 1h, which was maintained at least up to 168h. The CulturePal-Five system showed a drop in O₂ concentration down to approximately 5% within 24h, which was maintained up to 168h. The CO₂ concentration was also regulated to 3–5%, between 1h and 72h post-induction, in both systems. Simultaneous investigations utilizing several different gas concentrations necessitate an equivalent number of CO₂ incubators. Additionally, when other conditions such as culture temperature are altered, more incubators are required. In the case of investigations requiring a heat or cold shock stimulus, which is provided by a temperature-controlled water baths, the containers have to be hermetically sealed in order to prevent contaminations. This can cause alteration in the chamber gas concentrations. Therefore, control of the gas concentration within the container is imperative, although difficult. These issues could be overcome by application of the CulturePal systems as a single unit can be used for simultaneous investigations at three different O₂ conditions (21%, 5%, and <0.1% O₂). In addition, if the experiment requires 5% O₂ or <0.1% O₂ environment only, a conventional thermal incubator can be used for incubation, dispensing the need for expensive gas chambers and incubators. Based on these observations, we conclude that, although the CulturePal systems cannot be used to maintain a standard gas concentration during a culture medium exchange, it could be efficiently used to provide short-term hypoxic conditions or hypoxic stress. This system is also suitable for cell transportation, as a gas-atmosphere regulating reagent.

In our experiment, the rate of proliferation of MSCs was observed to be highest in 5% O₂ and the lowest in <0.1% O₂ conditions (Figure 4). These results are consistent with those of previous studies, where physiological hypoxia was observed to enhance MSC proliferation[17, 20, 21]. We also evaluated the cell viability at the three gas concentrations, and discovered that MSCs could maintain their viability even at <0.1% O₂ concentration conditions up to 72h after induction of hypoxia (Figure 5B), although some morphological alterations were observed (Figure 3), and the proliferative ability was observed to decrease under these severely hypoxic conditions (Figure 4). These results are also consistent with those of previous studies[17, 20, 21], where MSCs were reported to withstand severe hypoxia (<1% O₂) for at least 48h by increasing the availability of glucose, which facilitates the generation of energy under limited O₂ availability conditions. Therefore, MSCs, which are extremely durable under hypoxic conditions, could be utilized in cell therapies.

Cell senescence occurs in primary cells with long-term in vitro cultivation as a result of telomere shortening, oxidative stress, DNA damage, and aberrant mitogenic signaling[22]. The senescent cells demonstrated decreased cell proliferation and differentiation abilities[23], which decreased their potential for tissue regeneration. Hence, it is
important to prevent cell senescence during cell culture and transportation. p16INK4A is a well-known marker for cell senescence, as well as a tumor suppressor gene[24]. It has been reported that the down-regulation of p16INK4A mRNA expression resulted in a decrease in senescence, and restoration of the proliferative activity[24]. Our results have shown retained p16INK4A expression up to 72h at 5% O2 and <0.1% O2 conditions, demonstrating the reduced cell senescence characteristics. p16INK4A was up-regulated at 21% O2 conditions, indicating an induction of cell senescence. Therefore, we demonstrated that a hypoxic condition prevents the induction of cell senescence, which is consistent with the results of previous studies using O2 concentration-controlled chamber[9, 12]. Furthermore, p16 expression was significantly down-regulated in <0.1% O2 conditions compared to that in 5% O2 conditions, indicating that the repression of p16INK4A expression by hypoxic stimulus is correlated with the O2 concentration. To the best of our knowledge, ours is the first study reporting this phenomenon. Therefore, we suggest that 5% O2 concentration conditions would be suitable for maintenance of MSC quality. In addition, we have confirmed that this hypoxic culture system could easily replicate the experiments, using a short-term gas concentration-controlled chamber.

We have, however, identified two limitations in this study. First, the actual gas concentrations within the culture medium could not be measured. The O2 has to diffuse through the culture medium to reach the cells, which causes lower O2 tension near the cell surface compared to that controlled in the gas phase[25]. Second, our experiments were conducted on commercially available cells. It is important to confirm the reproducibility of our study results in cells obtained from individuals, and from different pathological states.

Conclusion

A short-term hypoxic condition induced at 5% O2 concentration promotes cell proliferation and represses up-regulation of the p16INK4A expression, without aggravating the cell viability of human MSCs. Furthermore, the mRNA expression of cell senescence marker p16INK4A might be altered proportionally to O2 concentration. Finally, we believe the CulturePal systems are suitable for providing an appropriate hypoxic condition for stem cell research and stem cell transportation.
