DIMENSION OF IN Variant MEASURES FOR AFFINE
ITERATED FUNCTION SYSTEMS

DE-JUN FENG

Abstract. Let \( \{S_i\}_{i \in \Lambda} \) be a finite contracting affine iterated function system (IFS) on \( \mathbb{R}^d \). Let \((\Sigma, \sigma)\) denote the two-sided full shift over the alphabet \( \Lambda \), and \( \pi : \Sigma \to \mathbb{R}^d \) be the coding map associated with the IFS. We prove that the projection of an ergodic \( \sigma \)-invariant measure on \( \Sigma \) under \( \pi \) is always exact dimensional, and its
Hausdorff dimension satisfies a Ledrappier-Young type formula. Furthermore, the result extends to average contracting affine IFSs. This completes several previous results and answers a folklore open question in the community of fractals. Some applications are given to the dimension of self-affine sets and measures.

1. Introduction

1.1. Motivation and the main result. Let \( \mathbb{R}^{d \times d} \) denote the set of real \( d \times d \) matrices. By an affine iterated function system (affine IFS) on \( \mathbb{R}^d \) we mean a finite family \( S = \{S_j\}_{j \in \Lambda} \) of affine mappings from \( \mathbb{R}^d \) to \( \mathbb{R}^d \), taking the form

\[
S_j(x) = M_j x + a_j, \quad j \in \Lambda,
\]

where \( M_j \in \mathbb{R}^{d \times d} \) and \( a_j \in \mathbb{R}^d \). Here, in contrast to the usual definition of affine IFS, we don’t assume that \( M_j \) are invertible or contracting (in the sense that \( \|M_j\| < 1 \) where \( \|\cdot\| \) is the matrix operator norm). We say that \( S \) is contracting if all \( M_j \) are contracting. It is well-known that if \( S \) is contracting, there exists a unique non-empty compact set \( K \subset \mathbb{R}^d \) such that

\[
K = \bigcup_{j \in \Lambda} S_j(K).
\]

We call \( K \) the self-affine set generated by \( S \). In particular, if all the maps in \( S \) are contracting similitudes, we call \( K \) a self-similar set.

Let \((\Sigma, \sigma)\) be the two-sided full shift over the alphabet \( \Lambda \), i.e. \( \Sigma = \Lambda^\mathbb{Z} \) and \( \sigma : \Sigma \to \Sigma \) is the left shift map. Endow \( \Sigma \) with the discrete product topology and let \( \mathcal{M}_\sigma(\Sigma) \) denote the space of \( \sigma \)-invariant Borel probability measures on \( \Sigma \).

Definition 1.1. Let \( m \in \mathcal{M}_\sigma(\Sigma) \). An affine IFS \( S = \{M_j x + a_j\}_{j \in \Lambda} \) is said to be average contracting with respect to \( m \) if, for \( m \)-a.e. \( x = (x_n)_{n=-\infty}^{\infty} \in \Sigma \), the top
Lyapunov exponent $\lambda(x)$ defined by

$$\lambda(x) = \lim_{n \to \infty} \frac{1}{n} \log \| M_{x_0} \cdots M_{x_{n-1}} \|$$

is strictly negative.

We remark that the above limit in defining $\lambda(x)$ exists and takes values in $[-\infty, \infty)$ for $m$-a.e. $x$. This follows from the Furstenberg-Kesten theorem [34] or Kingman’s sub-additive ergodic theorem [43].

Now let $m \in \mathcal{M}_e(\Sigma)$ and suppose that $\mathcal{S}$ is average contracting with respect to $m$. The canonical coding map $\pi : \Sigma \to \mathbb{R}^d$, given by

$$\pi(x) = \lim_{n \to \infty} S_{x_0} \circ S_{x_1} \circ \cdots \circ S_{x_n}(0)$$

$$= \lim_{n \to \infty} \left( a_{x_0} + M_{x_0} a_{x_1} + \cdots + M_{x_0} \cdots M_{x_{n-1}} a_{x_n} \right),$$

is well-defined on $\Sigma$ up to a set of zero $m$-measure ([15, 14]); see Section 3 for a self-contained proof. The push-forward measure $m \circ \pi^{-1}$, given by

$$m \circ \pi^{-1}(F) = m(\pi^{-1}(F)) \quad \text{for any Borel set } F \subset \mathbb{R}^d,$$

is called an invariant measure or stationary measure for $\mathcal{S}$. When $m$ is ergodic, $m \circ \pi^{-1}$ is called an ergodic invariant measure for $\mathcal{S}$. Moreover if $m$ is a Bernoulli product measure, $m \circ \pi^{-1}$ is called a self-affine measure generated by $\mathcal{S}$; if in addition, $\mathcal{S}$ consists of similarities, then $m \circ \pi^{-1}$ is called a self-similar measure.

The main purpose of this paper is to study the dimension of invariant measures for affine IFSs. Recall that for a probability measure $\eta$ on a metric space $X$, the local upper and lower dimensions of $\eta$ at $x \in X$ are defined respectively by

$$\overline{\dim}_{\text{loc}}(\eta, x) = \limsup_{r \to 0} \frac{\log \eta(B(x, r))}{\log r}, \quad \underline{\dim}_{\text{loc}}(\eta, x) = \liminf_{r \to 0} \frac{\log \eta(B(x, r))}{\log r},$$

where $B(x, r)$ stands for the closed ball of radius $r$ centered at $x$. If

$$\overline{\dim}_{\text{loc}}(\eta, x) = \underline{\dim}_{\text{loc}}(\eta, x),$$

the common value is denoted as $\dim_{\text{loc}}(\eta, x)$ and is called the local dimension of $\eta$ at $x$. We say that $\eta$ is exact dimensional if there exists a constant $C$ such that the local dimension $\dim_{\text{loc}}(\eta, x)$ exists and equals $C$ for $\eta$-a.e. $x \in X$. It is well-known that if $\eta$ is an exact dimensional measure in $\mathbb{R}^d$, the Hausdorff and packing dimensions of $\eta$ coincide and are equal to the involved constant $C$, and so are some other notions of dimension (e.g. entropy dimension); see [67, 21]. Recall that the Hausdorff and packing dimensions of $\eta$ are defined by

$$\dim_{\text{H}}(\eta) = \inf\{ \dim_{\text{H}} F : \eta(F) > 0 \text{ and } F \text{ is a Borel set} \},$$

$$\dim_{\text{P}}(\eta) = \inf\{ \dim_{\text{P}} F : \eta(\mathbb{R}^d \setminus F) = 0 \text{ and } F \text{ is a Borel set} \},$$

where $\dim_{\text{H}} F, \dim_{\text{P}} F$ stand for the Hausdorff and packing dimensions of $F$, respectively (cf. [22]).
A folklore open problem in fractal geometry asks whether every ergodic invariant measure for an affine IFS is exact dimensional. As the main result of this paper, we give the following confirmative answer.

**Theorem 1.2.** Let $S = \{M_j x + a_j \}_{j \in \Lambda}$ be an affine IFS on $\mathbb{R}^d$ and $m \in \mathcal{M}_\sigma(\Sigma)$. Suppose that $S$ is average contracting with respect to $m$. Let $\mu = m \circ \pi^{-1}$. Then

(i) $\dim_{\text{loc}}(\mu, x)$ exists for $\mu$-a.e. $x \in \mathbb{R}^d$.

(ii) Assume furthermore that $m$ is ergodic. Then $\mu$ is exact dimensional and $\dim_H \mu$ satisfies a Ledrappier-Young type dimension formula.

The precise dimension formula of $\mu$ and some of its applications will be given in Sections 1.2-1.3. Below we first give some background information about the above study.

The problem of the existence of local dimensions has a long history in smooth dynamical systems, as well as in the study of IFSs. It is of great importance in dimension theory of dynamical systems and fractal geometry. In [67], Young proved that an ergodic hyperbolic measure invariant under a $C^2$ surface diffeomorphism is always exact dimensional. (Here by hyperbolic one means that the measure has no zero Lyapunov exponent.) For a hyperbolic measure $\mu$ in high-dimensional $C^2$ systems, Ledrappier and Young [44] proved the existence of $\delta^u$ and $\delta^s$, the local dimensions along stable and unstable local manifolds, respectively, and the upper local dimension of $\mu$ is bounded by the sum of $\delta^u$ and $\delta^s$; moreover they obtained a formula for $\delta^u$ and $\delta^s$ in terms of conditional entropies and Lyapunov exponents, which nowadays is called “Ledrappier-Young formula”. Eckmann and Ruelle [18] indicated that it is unknown whether the local dimension of $\mu$ is equal to the sum of $\delta^u$ and $\delta^s$ if $\mu$ is a hyperbolic measure. Then the problem was referred as Eckmann-Ruelle conjecture, and was finally answered confirmatively by Barreira, Pesin and Schmeling in 1999 for $C^{1+\alpha}$ diffeomorphisms [10]. Later, the result of exact dimensionality was further extended by Qian and Xie [58] and Shu [64] to $C^2$ expanding endomorphisms and $C^2$ non-degenerate endomorphisms, respectively.

For the study of IFSs, it is well-known that if $S$ is a contractive IFS consisting of similarity maps, or more generally, a contracting $C^1$ conformal IFS, then under an additional separation condition (the so-called open set condition), the push-forward measure of any ergodic invariant measure under the coding map is exact dimensional with dimension given by the classical entropy divided by the Lyapunov exponent (cf. [12, 38, 54]). The result essentially follows from the Shannon-McMillan-Breiman theorem in entropy theory. However, the problem becomes much more complicated without assuming the open set condition. In [28], by introducing a notion of projection entropy and adopting some ideas from [44], Feng and Hu proved that for any contracting $C^1$ conformal IFS, the push-forward measure of every ergodic invariant measure under the coding map is exact dimensional, with dimension given by the projection entropy divided by the Lyapunov exponent. Later this result was further extended to some random self-similar measures [24, 63] and push-forward measures of ergodic invariant measures for some random conformal IFSs [49]. It is worth pointing out that the exact dimensionality of overlapping self-similar measures was
first claimed by Ledrappier; nevertheless no proof has been written out (cf. [55, p. 1619]). This property was also conjectured later by Fan, Lau and Rao in [26].

The first result for affine IFSs is due to Bedford [11] and McMullen [48], who independently calculated the Hausdorff and box-counting dimensions of a special class of planar self-affine sets (which are now called Bedford-McMullen carpets) and showed that they are usually different. McMullen [48] also implicitly proved the exact dimensionality of self-affine measures on the Bedford-McMullen carpets, and calculated the precise value of the dimension. Later, Gatzouras and Lalley [35] and Barański [1] obtained similar results for a class of more general carpet-like self-affine sets in the plane. In [42], Kenyon and Peres extended Bedford and McMullen’s result to higher dimensional self-affine carpets, and moreover, they proved the exact dimensionality and gave a Ledrappier-Young type dimension formula for arbitrary ergodic invariant measure on these carpets. For more related results on carpet-like self-affine sets, see the survey paper [23].

In [28], Feng and Hu proved that for each contracting invertible affine IFS in $\mathbb{R}^d$,

Theorem 1.2 holds under an additional assumption that the linear parts of the IFS commute (i.e. $M_i M_j = M_j M_i$). It remained open whether this additional assumption could be removed. Very recently, Bárány and Käenmäki [4] made a substantial progress. They proved that for contracting invertible affine IFSs, every planar self-affine measure (more generally, every self-affine measure in $\mathbb{R}^d$ having $d$ distinct Lyapunov exponents) is exact dimensional, and moreover, under certain domination condition on the linear parts $\{M_j\}$, the push-down of every quasi-Bernoulli measure on the self-affine set is exact dimensional, with dimension given by a Ledrappier-Young type formula. Some other partial results were also obtained in [2, 59, 31]. Along another direction, it is proved that for a given ergodic $m \in \mathcal{M}_o(\Sigma)$, $m \circ \pi^{-1}$ is exact dimensional for “almost all” contracting invertible affine IFSs satisfying $\|M_j\| < 1/2$ ([40, 39, 61]); however, the result does not apply to any concrete case.

Theorem 1.2 finally gives a full confirmative answer to the problem of the existence of local dimensions in the context of affine IFSs. It completes the aforementioned previous works on the problem.

Exact dimensionality and Ledrappier-Young type dimension formula play a significant role in many of the recent advances in dimension theory of self-affine sets and measures (see e.g. [2, 3, 4, 5, 6, 7, 8, 9, 17, 25, 37, 50, 57, 59]). In the remaining part of this section, we will present some applications of Theorem 1.2 along the line of this development.

The proof of Theorem 1.2 is based on some ideas from the work of Ledrappier and Young [44]. It also adopts and extends some ideas used in [28, 4, 58] for the construction of measurable partitions and the density estimates of associated conditional measures. Since our construction of measurable partitions is much different from these works (see Remark 4.3), and the IFSs in consideration may be non-invertible and non-contractive, many estimates of conditional measures need to be rebuilt or re-justified. A key part of our arguments is on the estimation of the so-called “transverse dimension” of these conditional measures, where significant efforts are made to handle the situation when the linear parts of the IFS do not
satisfy any domination condition (in such case the angles of Oseledets subspaces maybe substantially small). Our strategy is to build an induced dynamics so that we are able to focus on the trajectories where the angles of Oseledets subspaces are significantly large.

1.2. Dimension formulas. Throughout this subsection, under the assumptions of Theorem 1.2, we further assume that \( m \) is ergodic. We are going to present certain dimension formulas for \( \mu = m \circ \pi^{-1} \) and related conditional measures.

First notice that in this ergodic case, the condition (3) in Definition 1.1 is equivalent to
\[
\lambda := \lim_{n \to \infty} \frac{1}{n} \int \log \| M_{x_0} \cdots M_{x_{n-1}} \| \, dm(x) < 0.
\]

By Oseledets’ multiplicative ergodic theorem [51], there exist an integer \( 1 \leq s \leq d \), numbers \( \lambda = \lambda_1 > \cdots > \lambda_s \geq -\infty \), positive integers \( k_1, \ldots, k_s \) with \( \sum_{i=1}^s k_i = d \), and measurable linear subspaces
\[
\mathbb{R}^d = V^0_x \supseteq V^1_x \supseteq \cdots \supseteq V^s_x = \{0\}, \quad x \in \Sigma,
\]
such that for \( m \)-a.e. \( x = (x_n)_{n=-\infty}^\infty \),
\[
\begin{align*}
& (i) \quad M_{x_{n-1}} V^i_x \subset V^{i+1}_{x_n}, \\
& (ii) \quad \dim V^i_x = \sum_{j=i+1}^s k_j, \\
& (iii) \quad \lim_{n \to \infty} \frac{1}{n} \log \| M_{x_{n-1}} \cdots M_{x_{n-v}} \| = \lambda_{i+1} \quad \text{for} \quad v \in V^i_x \setminus V^{i+1}_x.
\end{align*}
\]

The numbers \( \lambda_1, \ldots, \lambda_s \) are called the Lyapunov exponents of \( (M_j)_{j \in \Lambda} \) with respect to \( m \), and \( k_i \) the multiplicity of \( \lambda_i \), \( i = 1, \ldots, s \). Recall that \( \pi(x) \) is well-defined for \( m \)-a.e. \( x \). Hence there exists a Borel set \( \Sigma' \subset \Sigma \) with \( \sigma(\Sigma') = \Sigma' \) and \( m(\Sigma') = 1 \) such that \( \pi \) is well-defined on \( \Sigma' \) and the above properties (i)-(iii) hold for \( x \in \Sigma' \).

We remark that these linear subspaces \( V^i_x \) only depend on \( i \) and \( x^- := (x_j)_{j=-\infty}^{-1} \) since by (i)-(iii), one has
\[
V^i_x = \left\{ v \in \mathbb{R}^d : \lim_{n \to \infty} \frac{1}{n} \log \| M_{x_{n-1}} \cdots M_{x_{n-v}} \| \leq \lambda_{i+1} \right\}.
\]

Using this property, we construct a family of measurable partitions \( \xi_0, \ldots, \xi_s \) of \( \Sigma' \) as follows:
\[
\xi_i(x) := \{ y \in \Sigma' : y^- = x^-, \pi y - \pi x \in V^i_x \},
\]
here \( \xi_i(x) \) is the \( \xi_i \)-atom that contains \( x \) (see Sections 2.2 and 4 for the details). Moreover, let
\[
\mathcal{P} = \{ [j]_0 \cap \Sigma' : j \in \Lambda \}
\]
be the canonical partition of \( \Sigma' \), where \( [j]_0 := \{ x = (x_n)_{n=-\infty}^\infty \in \Sigma : x_0 = j \} \). Define
\[
h_i = H_m(\mathcal{P} | \hat{\xi}_i), \quad i = 0, \ldots, s,
\]
where \( H_m(\cdot | \cdot) \) stands for the conditional entropy and \( \hat{\xi}_i \) is the \( \sigma \)-algebra generated by \( \xi_i \) (see Section 2.1 for the definitions).

Now we are ready to present the dimension formula for \( m \circ \pi^{-1} \).
Theorem 1.3. Let $S = \{M_j x + a_j\}_{j \in \Lambda}$ be an affine IFS on $\mathbb{R}^d$ and $m$ be an ergodic $\sigma$-invariant measure on $\Sigma$. Suppose that $S$ is average contracting with respect to $m$. Let $\mu = m \circ \pi^{-1}$. Then

$$\dim_H \mu = \sum_{i=0}^{s-1} \frac{h_{i+1} - h_i}{\lambda_{i+1}},$$

where $h_i$ are defined as in (1.5).

Next we give similar dimension formulas for certain conditional measures associated with $m$. For $i = 0, \ldots, s$, let $\{m^\xi_x\}$ be the system of conditional measures of $m$ associated with the partition $\xi_i$ (cf. Section 2.2). For a linear subspace $W$ of $\mathbb{R}^d$, let $W^\perp$ denote the orthogonal complement of $W$ in $\mathbb{R}^d$, and let $P_W : \mathbb{R}^d \rightarrow W$ denote the orthogonal projection from $\mathbb{R}^d$ to $W$.

Theorem 1.4. Under the assumptions of Theorem 1.3, for any $0 \leq i < j \leq s$ and $m$-a.e. $x \in \Sigma'$, the measures $m^\xi_x \circ \pi^{-1}$, $m^\xi_x \circ \pi^{-1} \circ (P_{(V_j^\perp)^{-1}})^{-1}$ are exact dimensional with

$$\dim_H (m^\xi_x \circ \pi^{-1}) = \sum_{\ell=1}^{s-1} \frac{h_{\ell+1} - h_{\ell}}{\lambda_{\ell+1}},$$

$$\dim_H \left( m^\xi_x \circ \pi^{-1} \circ (P_{(V_j^\perp)^{-1}})^{-1} \right) = \sum_{\ell=1}^{j-1} \frac{h_{\ell+1} - h_{\ell}}{\lambda_{\ell+1}},$$

Moreover, for $m$-a.e. $x \in \Sigma'$ and any $1 \leq j \leq s$,

$$\dim_{\text{loc}} \left( m \circ \pi^{-1} \circ (P_{(V_j^\perp)^{-1}})^{-1} \circ P_{(V_j^\perp)^{\perp}}(\pi x) \right) = \sum_{\ell=0}^{j-1} \frac{h_{\ell+1} - h_{\ell}}{\lambda_{\ell+1}}.$$

From the above theorem, we can deduce certain dimension conservation property for the measures $m^\xi_x \circ \pi^{-1}$ and $\mu$. To state the result, let $G(d, k)$ denote the Grassmannian manifold of $k$-dimensional linear subspaces of $\mathbb{R}^d$. For a Borel probability measure $\eta$ on $\mathbb{R}^d$ and $W \in G(d, k)$, let $\{\eta_{W,z} = \eta_{z^W}\}_{z \in \mathbb{R}^d}$ denote the system of conditional measures of $\eta$ associated with the measurable partition $\xi_W$ given by

$$\zeta_W = \{W + a : a \in W^\perp\}.$$  

These conditional measures are also called the slicing measures of $\eta$ along the subspace $W$ (cf. [47, §10.1]). Following Furstenberg [33], we give the following.

Definition 1.5. $\eta$ is said to be dimension conserving with respect to the projection $P_W$, if

$$\dim_H \eta = \dim_H \eta_{W,z} + \dim_H (\eta \circ (P_W)^{-1})$$

for $\eta$-a.e. $z \in \mathbb{R}^d$.

For $i \in \{0, \ldots, s-1\}$, define $\Pi_i : \Sigma' \rightarrow G(d, \sum_{j=i+1}^s k_j)$ by

$$\Pi_i(x) = V_x^i.$$
The push-forward measures \( m \circ (\Pi_i)^{-1}, i = 1, \ldots, s - 1 \), are called the Furstenberg measures or Furstenberg-Oseledets measures associated with \((M_j)_{j \in \Lambda}\) and \(m\). An ergodic measure \( \nu \in \mathcal{M}_\sigma(\Sigma) \) is said to be quasi-Bernoulli if there exists a positive constant \( C \) such that
\[
C^{-1}\nu([I]_0)\nu([J]_0) \leq \nu([IJ]_0) \leq C\nu([I]_0)\nu([J]_0)
\]
for any finite words \( I, J \) over \( \Lambda \), where
\[
[I]_0 := \{ x \in \Sigma : x_j = i_j \text{ for } 0 \leq j \leq n - 1 \}
\]
for \( I = i_0 \ldots i_{n-1} \). Similarly, we say that \( \nu \) is sub-multiplicative if there exists a positive constant \( C \) such that \( \nu([IJ]_0) \leq C\nu([I]_0)\nu([J]_0) \) for any finite words \( I, J \) over \( \Lambda \).

**Theorem 1.6.** Under the assumptions of Theorem 1.3, we further assume that \( s \geq 2 \). Let \( i \in \{1, \ldots, s - 1\} \). Then the following statements hold.

(i) For \( m \)-a.e. \( x \in \Sigma' \), \( m_\xi^0 \circ \pi^{-1} \) is dimension conserving with respect to \( P_{(V_\xi)^\perp} \) and moreover, the projected measure \( (m_\xi^0 \circ \pi^{-1}) \circ P_{(V_\xi)^\perp} \) is exact dimensional, and so are the slicing measures \( (m_\xi^0 \circ \pi^{-1})_{V_\xi^y} \) for \( (m_\xi^0 \circ \pi^{-1})\)-a.e. \( y \).

(ii) Assume that \( m \) is quasi-Bernoulli. Then for \( m \circ (\Pi_i)^{-1} \)-a.e. \( W \), \( \mu \) is dimension conserving with respect to \( P_W^\perp \), and moreover, the associated projected measure and almost all slicing measures are exact dimensional.

(iii) Assume that \( m \) is sub-multiplicative. Then for \( m \circ (\Pi_i)^{-1} \)-a.e. \( W \), there exists a subset \( A_W \) of \( \mathbb{R}^d \) with \( \mu(A_W) > 0 \) such that for every \( z \in A_W \),
\[
\dim_{\text{loc}}(\mu_{W,z}) = \sum_{\ell=1}^{s-1} \frac{h_{\ell+1} - h_{\ell}}{\lambda_{\ell+1}},
\]
\[
\dim_{\text{loc}}(\mu \circ P_{W^\perp}^{-1}, P_{W^\perp}(z)) = \sum_{\ell=0}^{i-1} \frac{h_{\ell+1} - h_{\ell}}{\lambda_{\ell+1}},
\]
and so, \( \dim_{\text{H}} \mu = \dim_{\text{loc}}(\mu_{W,z}) + \dim_{\text{loc}}(\mu \circ P_{W^\perp}^{-1}, P_{W^\perp}(z)) \). When \( m \) is quasi-Bernoulli then one can take the set \( A_W \) such that \( \mu(A_W) = 1 \).

We remark that part (ii) of Theorem 1.6 was previously proved in [4] under the assumptions that \( \mathcal{S} \) is contracting, invertible and its linear parts satisfy certain domination condition. According to part (iii) of the theorem, when \( m \) is sub-multiplicative, \( \mu \) partially satisfies dimension conservation. It is unknown whether part (ii) always holds when \( m \) is only assumed to be ergodic. However, as is illustrated in the following theorem, this is true in the special case that the linear parts of the IFS commute.

**Theorem 1.7.** Let \( \mathcal{S} = \{M_jx + a_j\}_{j \in \Lambda} \) be an affine IFS on \( \mathbb{R}^d \), average contracting with respect to an ergodic \( m \in \mathcal{M}_\sigma(\Sigma) \). Let \( \mu = m \circ \pi^{-1} \). Assume \( s \geq 2 \) and in addition that \( M_jM_{j'} = M_jM_{j'} \) for \( j, j' \in \Lambda \). Then for \( i \in \{1, \ldots, s - 1\} \), \( V_i^x \) is constant \( m \)-a.e., denoted by \( W_i \), moreover, \( \mu \) is dimension conserving with respect to \( P_{(W_i)^\perp} \).
It is worth pointing out that if $\mu$ is a contracting self-similar measure in $\mathbb{R}^d$ with a finite rotation group, then for each proper subspace $W$ of $\mathbb{R}^d$, $\mu$ is dimension conserving with respect to $P_W$. The result is due to Falconer and Jin [24]. Under an additional assumption of the strong separation condition, this result can be alternatively derived from a general result of Furstenberg (cf. [33, Theorem 3.1]). We remark that this dimension conservation property also extends to ergodic invariant measures for rotation-free self-similar IFSs (see Remark 6.3). Furthermore, we remark that Theorem 1.6-1.7 can be applied to analyze slices and projections of certain self-affine sets (see Remark 7.5).

1.3. Semi-continuity of dimension and applications. Here we present a semi-continuity result on the dimension of ergodic invariant measures for affine IFSs and give its application to the dimension of self-affine sets. Again let $S = \{M_ix + a_i\}_{i \in \Lambda}$ be an affine IFS on $\mathbb{R}^d$, average contracting with respect to an ergodic invariant measure $m$ on $\Sigma$. Write $a = (a_i)_{i \in \Lambda}$. To emphasize the dependence on $a$, let $\pi_a$ be the coding map associated to $S$ and let $h_{i,a}$ ($i = 1, \ldots, s$) be the conditional entropies of $m$ defined in (1.5). Then we have the following.

**Theorem 1.8.**

1. The mapping $a \mapsto h_{i,a}$ is upper semi-continuous for each $i \in \{1, \ldots, s\}$.

2. Moreover, the mapping $a \mapsto \dim_H (m \circ (\pi_a)^{-1})$ is lower semi-continuous.

Part (1) of the above result was first proved by Rapaport [59, Lemma 8] in the case when $m$ is a Bernoulli product measure and $S$ is invertible and contracting. Part (2) was shown by Hochman and Shmerkin [36] for a special class of self-similar measures on $\mathbb{R}$. In Remark 8.2 we give a further extension of Theorem 1.8.

Below we present an application of Theorem 1.8 to the dimension of self-affine sets and associated stationary measures. For this purpose, in the remaining part of this subsection we assume that $\|M_j\| < 1$ for $j \in \Lambda$ and write $M = (M_j)_{j \in \Lambda}$. Let $K(M, a)$ be the self-affine set generated by the IFS $S = \{M_ix + a_j\}_{j \in \Lambda}$. In 1988, Falconer [20] introduce a quantity associated to $M$, nowadays usually called the **affinity dimension** $\dim_{\text{AFF}}(M)$, which is always an upper bound for the upper box-counting dimension of $K(M, a)$, and such that when $\|M_j\| < 1/2$ for all $j$, then for $\mathcal{L}^{d(\Lambda)}$-a.e. $a$, $\dim_H K(M, a) = \min(d, \dim_{\text{AFF}}(M))$. In fact, Falconer proved this with $1/3$ as the upper bound on the norms; it was subsequently shown by Solomyak [65] that $1/2$ suffices.

The analogue of affinity dimension for measures is the Lyapunov dimension, which we denote $\dim_{\text{LY}}(m, M)$; see Section 7 for its definition. In [40], Jordan, Pollicott and Simon proved that the Lyapunov dimension $\dim_{\text{LY}}(m, M)$ is always an upper bound for the Hausdorff dimension of $m \circ (\pi_a)^{-1}$, and moreover when $\|M_j\| < 1/2$ for all $j$, then for $\mathcal{L}^{d(\Lambda)}$-a.e. $a$, $\dim_H m \circ (\pi_a)^{-1} = \min(d, \dim_{\text{LY}}(m, M))$.

Recall a set in a topological space is said to be of **first category** if it can be written as the countable union of nowhere dense subsets. As an application of Theorem 1.8, we get the following result.

**Theorem 1.9.** Suppose that $\|M_j\| < 1/2$ for $j \in \Lambda$. Then the following hold.
(i) For every ergodic $\sigma$-invariant measure $m$ on $\Sigma$, the exceptional set
\[ \{a \in \mathbb{R}^{d[\Lambda]} : \dim_H (m \circ (\pi_a)^{-1}) \neq \min(d, \dim_{LY}(m, M)) \} \]
is of first category in $\mathbb{R}^{d[\Lambda]}$. 

(ii) The exceptional set
\[ \{a \in \mathbb{R}^{d[\Lambda]} : \dim_H K(M, a) \neq \min(d, \dim_{AFF}(M)) \} \]
is of first category in $\mathbb{R}^{d[\Lambda]}$. 

The above result says that these exceptional sets are also small in a topological sense. A fundamental and challenging question is to specify those translation vectors not lying in the exception sets. Significant progresses have been made recently in [2, 25, 4, 59], showing that under certain additional assumptions, the Hausdorff and Lyapunov dimensions of a self-affine measure (or more generally, the push-forward of a quasi-Bernoulli measure) coincide if the involved Furstenberg measures have enough large dimension. In next theorem we will drop off some redundant assumptions used in these works and further extend the result to the push-forward measures of ergodic sub-multiplicative measures. 

Recall that for a Borel probability measure $\eta$ on a metric space, its \textit{upper Hausdorff dimension} $\dim^*_H \eta$ is the smallest Hausdorff dimension of a Borel set $F$ of $\eta$ measure 1. Set $d_0 = 0$ and $d_\ell = k_1 + \cdots + k_\ell$ for $1 \leq \ell \leq s$.

\begin{theorem}
Let $\mathcal{S} = \{M_j x + a_j\}_{j \in \Lambda}$ be a contracting affine IFS on $\mathbb{R}^d$ satisfying the strong separation condition and $m \in M_\sigma(\Sigma)$ be ergodic and sub-multiplicative. Let $i$ be the unique element in $\{1, \ldots, s\}$ so that $d_{i-1} \leq \dim_{LY}(m, M) < d_i$. Then
\begin{equation}
\dim_H m \circ \pi^{-1} = \dim_{LY}(m, M)
\end{equation}
provided one of the following conditions holds:

\begin{enumerate}
  \item \label{a} $s = 1$.
  \item \label{b} $i = s > 1$, $\lambda_s \neq -\infty$ and

\begin{equation}
\dim_H (m \circ (\Pi_{s-1})^{-1}) + \dim_{LY}(m, M) \geq d_{s-1}(d - d_{s-1} + 1).
\end{equation}

\item \label{c} $1 \leq i \leq s - 1$, and

\begin{equation}
\dim^*_H (m \circ (\Pi_i)^{-1}) - \dim_{LY}(m, M) \geq d_i(d - d_i - 1),
\end{equation}
\begin{equation}
\dim^*_H (m \circ (\Pi_{i-1})^{-1}) + \dim_H m \circ \pi^{-1} \geq d_{i-1}(d - d_{i-1} + 1).
\end{equation}
\end{enumerate}

The conditions \ref{b}, \ref{c} in the above theorem were introduced in [59] and [3], respectively, in slightly stronger forms. For a contracting invertible affine IFS, Ráppaport [59] proved the implication \ref{b} $\Rightarrow$ \ref{1.11} in the case when $m$ is Bernoulli and $(M_j)_{j \in \Lambda}$ satisfies an irreducibility assumption; whilst Bárány and Käenmäki [3] proved \ref{1.11} under the assumptions that the conditions \ref{1.13}-\ref{1.14} hold for all $i \in \{1, \ldots, s - 1\}$, $m$ is Bernoulli and $d = 2$, or $m$ is quasi-Bernoulli and $(M_j)_{j \in \Lambda}$ satisfies a domination condition.

We remark that \ref{1.14} always holds whenever $i = 1$, since $d_0 = 0$. It is worth pointing out that for every affine IFS $\mathcal{S} = \{M_j x + a_j\}_{j \in \Lambda}$ on $\mathbb{R}^d$, there exists at
least one ergodic \( m \in \mathcal{M}_\sigma(\Sigma) \), called K"aenm"aki measure, so that \( \dim_{\text{LY}}(m, M) = \dim_{\text{AFF}}(M) \). This was first proved by K"aenm"aki [41] in the case when \( S \) is invertible, and it extends to the general case by the sub-additive thermodynamic formalism [16]. Very recently, Bochi and Morris [13] showed that whenever \( S \) is invertible, each K"aenm"aki measure is sub-multiplicative. Hence for an invertible \( S \) satisfying the strong separation condition, if one of the conditions (a)-(c) in Theorem 1.10 fulfills for some K"aenm"aki measure \( m \), then \( \dim_H K(M, a) = \dim_{\text{AFF}}(M) = \dim_H m \circ \pi^{-1} \).

To check the conditions (b)-(c) in Theorem 1.10, one needs to estimate the (upper) Hausdorff dimension of Furstenberg measures \( m \circ (\Pi_i)^{-1} \). So far there have been only a few dimensional results on these measures. In the case \( d = 2 \), Hochman and Solomyak [37] calculated the Hausdorff dimension of Furstenberg measures for Bernoulli \( m \) under some mild assumptions. In [8, Sect. 2.4], Bárány, Rams and Simon determined the Hausdorff dimension of Furstenberg measures for some special triangular affine IFSs in \( \mathbb{R}^d \), in which \( m \) could be any ergodic measure.

We remark that the conditions of Theorem 1.10 might not be sharp. Very recently, Bárány, Hochman and Rapaport [3] made a significant progress in dimension theory of affine IFSs, showing that the Hausdorff and affinity dimensions of a planar self-affine set coincide under the strong separation condition and certain irreducibility assumption; and similarly, the Hausdorff and Lyapunov dimensions of a planar self-affine measure coincide under the same assumptions.

1.4. Organization of the paper. The paper is organized as follows. In Section 2, we provide some density results about conditional measures, and present a version of Oseledets’s multiplicative ergodic theorem due to Froyland et al. [32]. In Section 3, we give some auxiliary results on the coding maps for average contracting affine IFSs. In Section 4, we construct a finite family of measurable partitions of \( \Sigma \) for a given average contracting affine IFS and give some necessary properties. In Section 5 we prove an inequality for the transverse dimensions of the conditional measures associated with these measurable partitions. In Section 6, we prove Theorems 1.2-1.4, 1.6-1.7. In Section 7, we give some properties of Lyapunov dimension. In Section 8, we prove Theorems 1.8-1.10.

2. Preliminaries

In this section, we first give the definitions and some properties of conditional entropies and conditional measures. Then we collect some known facts about induced transformations and derive a useful result (Lemma 2.11). In the end, we present a version of Oseledets’ multiplicative ergodic theorem due to Froyland et al. [32].

2.1. Conditional information and entropy. Let \((X, \mathcal{B}, m)\) be a probability space. For a sub-\(\sigma\)-algebra \(\mathcal{A}\) of \(\mathcal{B}\) and \(f \in L^1(X, \mathcal{B}, m)\), we denote by \(E_m(f|\mathcal{A})\) the the conditional expectation of \(f\) given \(\mathcal{A}\). For a countable \(\mathcal{B}\)-measurable partition \(\xi\) of \(X\), we denote by \(I_m(\xi|\mathcal{A})\) the conditional information of \(\xi\) given \(\mathcal{A}\), which is given
by the formula
\begin{equation}
I_m(\xi|A) = -\sum_{A \in \xi} \chi_A \log E_m(\chi_A|A),
\end{equation}
where \(\chi_A\) is the characteristic function on \(A\). The conditional entropy of \(\xi\) given \(A\), written as \(H_m(\xi|A)\), is defined by the formula

\[ H_m(\xi|A) = \int I_m(\xi|A) \, dm. \]

(See e.g. [53, 66] for more details.) The above information and entropy are unconditional when \(A = \mathcal{N}\), the trivial \(\sigma\)-algebra consisting of sets of measure zero and one, and in this case we write

\[ I_m(\xi|\mathcal{N}) = I_m(\xi) \quad \text{and} \quad H_m(\xi|\mathcal{N}) = H_m(\xi). \]

For a countable partition \(\xi\), we use \(\hat{\xi}\) to denote the \(\sigma\)-algebra generated by \(\xi\). If \(\xi_1, \ldots, \xi_n\) are countable partitions, then \(\xi_1 \vee \cdots \vee \xi_n = \bigvee_{i=1}^n \xi_i\) denotes the partition consists of the sets \(A_1 \cap \cdots \cap A_n\) with \(A_i \in \xi_i\). Similarly for \(\sigma\)-algebras \(\mathcal{A}_1, \mathcal{A}_2, \ldots\), \(\mathcal{A}_1 \vee \mathcal{A}_2 \vee \cdots\) or \(\bigvee_i \mathcal{A}_i\) denotes the \(\sigma\)-algebra generated by \(\bigcup_i \mathcal{A}_i\).

In the following lemma, we list some basic properties of the (conditional) information and entropy.

**Lemma 2.1** (cf. [53]). Let \(T\) be a measure-preserving transformation of a separable probability space \((X, \mathcal{B}, m)\). Let \(\xi, \eta\) be two countable Borel partitions of \(X\) with \(H_m(\xi) < \infty\), \(H_m(\eta) < \infty\), and \(\mathcal{A}\) a sub-\(\sigma\)-algebra of \(\mathcal{B}\). Then we have

(i) \(E_m(f|\mathcal{A}) \circ T = E_m(f \circ T|T^{-1}\mathcal{A})\) for \(f \in L^1(X, \mathcal{B}, m)\).
(ii) \(I_m(\xi|\mathcal{A}) \circ T = I_m(T^{-1}\xi|T^{-1}\mathcal{A})\).
(iii) \(I_m(\xi \vee \eta|\mathcal{A}) = I_m(\xi|\mathcal{A}) + I_m(\eta|\hat{\xi} \vee \mathcal{A})\).
(iv) \(H_m(\xi \vee \eta|\mathcal{A}) = H_m(\xi|\mathcal{A}) + H_m(\eta|\hat{\xi} \vee \mathcal{A})\).
(v) If \(\mathcal{A}_1 \subset \mathcal{A}_2 \subset \cdots\) is an increasing sequence of sub-\(\sigma\)-algebras with \(\mathcal{A}_n \uparrow \mathcal{A}\), then \(\lim_{n \to \infty} I_m(\xi|\mathcal{A}_n) \in L^1\), and \(I_m(\xi|\mathcal{A}_n)\) converges almost everywhere and in \(L^1\) to \(I_m(\xi|\mathcal{A})\). In particular, \(\lim_{n \to \infty} H_m(\xi|\mathcal{A}_n) = H_m(\xi|\mathcal{A})\).

Below we present an additional property of the conditional expectation.

**Lemma 2.2** ([28, Lemma 3.10]). Let \((X, \mathcal{B}, m)\) be a probability space and \(\mathcal{A}\) a sub-\(\sigma\)-algebra of \(\mathcal{B}\). Let \(A \in \mathcal{B}\) with \(m(A) > 0\). Then

\[ E_m(\chi_A|\mathcal{A})(x) > 0 \]

for \(m\)-a.e. \(x \in A\).

The following lemma is a variant of Maker’s ergodic theorem ([46]).

**Lemma 2.3** ([45], Corollary 1.6, p. 96). Let \(T\) be a measure-preserving transformation of a probability space \((X, \mathcal{B}, m)\). Let \(g_k \in L^1(X, \mathcal{B}, m)\) be a sequence that converges almost everywhere and in \(L^1\) to \(g \in L^1(X, \mathcal{B}, m)\). Then

\[ \lim_{k \to +\infty} \frac{1}{k} \sum_{j=0}^{k-1} g_{k-j}(T^j x) = E_m(g|\mathcal{T})(x) \]
In almost everywhere and in $L^1$.

2.2. **Conditional measures.** Here we give a brief introduction to Rohlin’s theory of Lebesgue spaces, measurable partitions and conditional measures. The reader is referred to [60, 52, 19] for more details.

A probability space $(X, \mathcal{B}, m)$ is called a **Lebesgue space** if it is isomorphic to a probability space which is the union of $[0, s]$ ($0 \leq s \leq 1$) with Lebesgue measure and a finite or countable number of atoms. Now let $(X, \mathcal{B}, m)$ be a Lebesgue space. A **measurable partition** $\eta$ of $X$ is a partition of $X$ such that, up to a set of measure zero, the quotient space $X/\eta$ is separated by a countable number of measurable sets $\{B_i\}$. The quotient space $X/\eta$ with its inherited probability space structure, written as $(X_\eta, \mathcal{B}_\eta, m_\eta)$, is again a Lebesgue space. Also, any measurable partition $\eta$ determines a sub-$\sigma$-algebra of $\mathcal{B}$, denoted by $\hat{\eta}$, whose elements are unions of elements of $\eta$. Conversely, any sub-$\sigma$-algebra $\mathcal{B}'$ of $\mathcal{B}$ is also countably generated, say by $\{B'_i\}$, and therefore all the sets of the form $\bigcap A_i$, where $A_i = B'_i$ or its complement, form a measurable partition. In particular, $\mathcal{B}$ itself is corresponding to a partition into single points. An important property of Lebesgue spaces and measurable partitions is the following.

**Theorem 2.4** (Rohlin [60]). Let $\eta$ be a measurable partition of a Lebesgue space $(X, \mathcal{B}, m)$. Then, for every $x$ in a set of full $m$-measure, there is a probability measure $m^x_\eta$ defined on $\eta(x)$, the element of $\eta$ containing $x$. These measures are uniquely characterized (up to sets of $m$-measure 0) by the following properties: if $A \subset X$ is a measurable set, then $x \mapsto m^x_\eta(A)$ is $\hat{\eta}$-measurable and $m(A) = \int m^x_\eta(A) dm(x)$. These properties imply that for any $f \in L^1(X, \mathcal{B}, m)$, $m^x_\eta(f) = E_m(f|\hat{\eta})(x)$ for $m$-a.e. $x$, and $m(f) = \int E_m(f|\hat{\eta}) dm$.

The family of measures $\{m^x_\eta\}$ in the above theorem is called the **canonical system of conditional measures** associated with $\eta$.

Throughout the remaining part of this subsection, we assume that $(X, \mathcal{B}, m)$ is a Lebesgue space. Suppose that $Y$ is a complete separable metric space and $\pi : X \to Y$ is a $\mathcal{B}$-measurable map. Denote $\gamma := \mathcal{B}(Y)$, the Borel-$\sigma$-algebra on $Y$.

According to Rohlin’s theory (cf. [60, Section 2.5], [52, Chapter IV]), the mapping $\pi$ induces a measurable partition

$$\xi = \{\pi^{-1}(y) : y \in Y\} \quad (2.2)$$

of $X$ with $\tilde{\xi} = \pi^{-1}\gamma$ (mod 0), and $(X_\xi, \mathcal{B}_\xi, m_\xi)$ is isomorphic (mod 0) to $(Y, \gamma, m \circ \pi^{-1})$. The system of conditional measures $\{m^x_\xi\}$ is also called the **disintegration of $m$ with respect to $\pi$**.

For $y \in Y$, we use $B(y, r)$ to denote the closed ball in $Y$ of radius $r$ centered at $y$. Moreover we write for $x \in X$,

$$B^x(y, r) = \pi^{-1}B(\pi x, r). \quad (2.3)$$
Furthermore, we say that $Y$ is a Besicovitch space if $Y$ is a complete separable metric space and the Besicovitch covering lemma (see e.g. [47]) holds in $Y$. Besicovitch spaces include, for instance, Euclidean spaces, compact finite-dimensional Riemannian manifolds and complete separable ultrametric spaces.

**Lemma 2.5.** Let $\pi : X \to Y$ be a measurable mapping from a Lebesgue space $(X, \mathcal{B}, m)$ to a Besicovitch space $Y$. Let $\eta$ be a measurable partition of $X$. Then the following properties hold.

1. Let $A \in \mathcal{B}$. Then for $m$-a.e. $x \in X$,

$$
\lim_{r \to 0} \frac{m_\eta^n(B^{\pi}(x, r) \cap A)}{m_\eta^n(B^{\pi}(x, r))} = E_m(\chi_A|\hat{\eta} \vee \pi^{-1}\gamma)(x).
$$

2. Let $\alpha$ be a finite or countable measurable partition of $X$. Then for $m$-a.e. $x \in X$,

$$
\lim_{r \to 0} \log \frac{m_\eta^n(B^{\pi}(x, r) \cap \alpha(x))}{m_\eta^n(B^{\pi}(x, r))} = -I_m(\alpha|\hat{\eta} \vee \pi^{-1}\gamma)(x).
$$

Furthermore, set

$$
g(x) = -\inf_{r > 0} \log \frac{m_\eta^n(B^{\pi}(x, r) \cap \alpha(x))}{m_\eta^n(B^{\pi}(x, r))}
$$

and assume $H_m(\alpha) < \infty$. Then $g \geq 0$ and $g \in L^1(X, \mathcal{B}, m)$.

**Proof.** These properties have been proved in [28, Lemma 3.3, Proposition 3.5] in the case when $Y = \mathbb{R}^d$. The proofs there remain valid for the general case when $Y$ is a Besicovitch space.

**Remark 2.6.** In the above lemma, we have $E_m(\chi_A|\hat{\eta} \vee \pi^{-1}\gamma) = E_m(\chi_A|\hat{\xi} \vee \tilde{\xi})$ and $I_m(\alpha|\hat{\eta} \vee \pi^{-1}\gamma) = I_m(\alpha|\hat{\xi} \vee \tilde{\xi})$ $m$-a.e., where $\xi$ is given by (2.2). This is because $\tilde{\xi} = \pi^{-1}\gamma$ (mod 0).

**Definition 2.7.** Two probability measures $m_1$ and $m_2$ on a measurable space $(X, \mathcal{B})$ are said to be strongly equivalent if there exists a positive constant $C$ such that $C^{-1}m_1(A) \leq m_2(A) \leq Cm_1(A)$ for all $A \in \mathcal{B}$.

**Lemma 2.8.** Let $\pi : X \to Y$ be a measurable mapping from a Lebesgue space $(X, \mathcal{B}, m_1)$ to a Besicovitch space $Y$. Let $\xi$ be the measurable partition of $X$ given in (2.2). Suppose $m_2$ is another probability measure on $(X, \mathcal{B})$ strongly equivalent to $m_1$. Then for $m_1$-a.e. $x$, $(m_1)^{\xi}_2$ and $(m_2)^{\xi}_2$ are strongly equivalent.

**Proof.** Since $m_1$ and $m_2$ are strongly equivalent, there exists a positive constant $C$ such that $C^{-1}m_1(B) \leq m_2(B) \leq Cm_1(B)$ for all $B \in \mathcal{B}$. Pick a countable subset $\mathcal{B}'$ of $\mathcal{B}$ such that $\sigma(\mathcal{B}') = \mathcal{B}$, where $\sigma(\mathcal{B}')$ stands for the $\sigma$-algebra generated by $\mathcal{B}'$. Applying Lemma 2.5(1) (in which we take $\eta = \mathcal{N}$) to $m_1$ and $m_2$ yields that for $m_1$-a.e. $x$,

$$
(m^{\xi}_2)(A) = \lim_{r \to 0} \frac{m_2(B^{\pi}(x, r) \cap A)}{m_2(B^{\pi}(x, r))} (i \in \{1, 2\}, A \in \mathcal{B}').
$$
It implies that for $m_1$-a.e $x$,

$$(2.4) \quad C^{-2}(m_1)\xi(A) \leq (m_2)\xi(A) \leq C^2(m_1)\xi(A)$$

for all $A \in \mathcal{B}'$. Since $\sigma(\mathcal{B}') = \mathcal{B}$, for $m_1$-a.e. $x$, (2.4) holds for all $A \in \mathcal{B}$. This completes the proof of the lemma. $\square$

**Lemma 2.9.** Let $\pi : X \to Y$ be a measurable mapping from a Lebesgue space $(X, \mathcal{B}, m)$ to a Besicovitch space $Y$. Let $\xi$ be the measurable partition of $X$ given in (2.2). Suppose $A \in \mathcal{B}$ with $m(A) > 0$ and let $m_A$ be the probability measure given by $m_A(E) = m(A \cap E)/m(A)$ for $E \in \mathcal{B}$. Then for $m$-a.e. $x \in A$, $(m_A)\xi = (m_2)\xi_A$, that is,

$$(m_A)\xi(E) = \frac{m_\xi(A \cap E)}{m_\xi(A)} \quad \text{for all } E \in \mathcal{B}.$$ 

**Proof.** Pick a countable subset $\mathcal{B}'$ of $\mathcal{B}$ such that $\sigma(\mathcal{B}') = \mathcal{B}$. Applying Lemma 2.5(1) (in which we take $\eta = \mathcal{N}$) to $m_A$ and $m$ yields that for $m$-a.e. $x \in A$, for all $E \in \mathcal{B}'$,

$$(m_A)\xi(E) = \lim_{r \to 0} \frac{m_A(B^\pi(x, r) \cap E)}{m_A(B^\pi(x, r))} = \lim_{r \to 0} \frac{m(B^\pi(x, r) \cap E \cap A)}{m(B^\pi(x, r) \cap A)} = \lim_{r \to 0} \frac{m(B^\pi(x, r) \cap E \cap A)/m(B^\pi(x, r))}{m(B^\pi(x, r) \cap A)/m(B^\pi(x, r))} = m_\xi(A \cap E)/m_\xi(A).$$

Since $\sigma(\mathcal{B}') = \mathcal{B}$, for $m$-a.e. $x \in A$ the equality $(m_A)\xi(E) = m_\xi(A \cap E)/m_\xi(A)$ holds for all $E \in \mathcal{B}$. This completes the proof of the lemma. $\square$

**2.3. Induced transformations.** Let $(X, \mathcal{B}, m, T)$ be an invertible measure-preserving system. Fix $N \in \mathbb{N}$ and $F \in \mathcal{B}$ with $m(F) > 0$. By the Poincaré recurrence theorem, the first return map to $F$ associated with $T^N$, defined by

$$r_F(x) = \inf\{n \geq 1 : T^{Nn}(x) \in F\},$$

exists almost everywhere. The map $T_F : F \to F$ defined almost everywhere by

$$T_F(x) = T^{Nn_F(x)}(x)$$

is called the transformation induced by $T^N$ on the set $F$.

For $n \geq 1$, set $F_n = \{x \in F : r_F(x) = n\}$. Write

$$\mathcal{B}|_F := \{B \cap F : B \in \mathcal{B}\}, \quad m_F := \frac{1}{m(F)} m|_F,$$

where $m|_F$ stands for the restriction of $m$ on $F$, that is, $m|_F(B) = m(B \cap F)$ for $B \in \mathcal{B}$. The following result is well-known (see e.g. [19, pp. 61-63] and [56, pp. 257-258] for a proof).

**Lemma 2.10.** (i) The induced transformation $T_F$ is a measure-preserving transformation on the space $(F, \mathcal{B}|_F, m_F)$. 

---

**Note:** The text is a segment from a mathematical document, discussing transformations and Poincaré recurrence theorems in the context of measure theory and dynamical systems. The content includes detailed mathematical proofs and definitions, aligned with the natural reading format of a mathematical text.
(ii) The family of sets \( \{T^{Nj}F_n\}_{n \geq 1, 0 \leq j \leq n-1} \) are disjoint, and hence
\[
\sum_{n=1}^{\infty} n \, m(F_n) \leq 1.
\]

(iii) \(-\sum_{n=1}^{\infty} m(F_n) \log m(F_n) < \infty\).

Set \( \mathcal{I} = \{ B \in \mathcal{B} : T^{-1}(B) = B \} \) and \( \mathcal{I}_F := \{ B \in \mathcal{B} : (T_F)^{-1}(B) = B \} \). The following result will be needed in the proof of Theorem 1.2.

Lemma 2.11. Let \( g \in L^1(X, \mathcal{B}, m) \). Set \( G(x) = \sum_{r_F(x)=0}^{N r_F(x)-1} g(T^r x) \) for \( x \in F \). Then \( G \in L^1(F, \mathcal{B}|_F, m|_F) \). Moreover,
\[
(2.5) \quad N E_m(g|\mathcal{I})(x) = \frac{E_m(G|\mathcal{I}_F)(x)}{E_m(r_F|\mathcal{I}_F)(x)}
\]
for \( m \)-a.e. \( x \in F \).

Proof. First notice that
\[
\int_F |G| \, dm_F = \frac{1}{m(F)} \sum_{n=1}^{\infty} \int_{F_n} |G| \, dm
\]
\[
\leq \frac{1}{m(F)} \sum_{n=1}^{\infty} \sum_{p=0}^{N_n-1} \int_{F_n} |g \circ T^p| \, dm
\]
\[
= \frac{1}{m(F)} \sum_{n=1}^{\infty} \sum_{p=0}^{N_n-1} \int_{T^p F_n} |g| \, dm \quad \text{(since \( T \) is invertible and preserves \( m \))}
\]
\[
= \frac{1}{m(F)} \sum_{k=0}^{N-1} \sum_{n=1}^{N-1} \sum_{j=0}^{n-1} \int_{T^{N_j+k} F_n} |g| \, dm
\]
\[
\leq \frac{N}{m(F)} \int_X |g| \, dm,
\]
where in the last inequality we have used the fact that for any \( k \), the sets in the collection \( \{T^{N_j+k}F_n : n \in \mathbb{N}, 0 \leq j \leq n-1 \} \) are disjoint (see Lemma 2.10(ii)).

Hence \( G \in L^1(m|_F) \). Below we prove (2.5).

Consider the sequence of integer-valued functions \( (n_k(x))_{k=0}^{\infty} \), which are defined on \( F \) almost everywhere by \( n_0(x) = 0 \), and
\[
n_k(x) = \sum_{j=0}^{k-1} r_F(T_F^j x) \quad \text{for} \ k \geq 1,
\]
where \( T_F^j := (T_F)^j \). Clearly, \( n_k(x) \geq k \) and \( T_F^k(x) = T^{Nn_k(x)}(x) \). Hence,

\[
\sum_{j=0}^{k-1} G(T_F^j x) = \sum_{j=0}^{k-1} \sum_{p=0}^{Nn_k(T_F^j x)-1} g(T^p(T_F^j x)) \\
= \sum_{j=0}^{k-1} Nn_k(T_F^j x)-1 \sum_{p=0}^{Nn_k(T_F^j x)-1} g(T^Nn_k(x)+p x) \\
= \sum_{j=0}^{k-1} Nn_{j+1}(x)-1 \sum_{\ell=Nn_j(x)} g(T^\ell x) \\
= \sum_{i=0}^{Nn_k(x)-1} g(T^i x).
\]

By the Birkhoff ergodic theorem, we have

\[
\lim_{k \to +\infty} \frac{1}{n_k} \sum_{j=0}^{k-1} G(T_F^j x) = \lim_{k \to +\infty} \frac{1}{n_k} \sum_{i=0}^{Nn_k(x)-1} g(T^i x) = NE_m(g|\mathcal{F})(x)
\]

for \( m \)-a.e. \( x \in F \). Applying the Birkhoff ergodic theorem again, we have

\[
\lim_{k \to +\infty} \frac{1}{k} \sum_{j=0}^{k-1} G(T_F^j x) = E_{m_F}(G|\mathcal{F})(x) \quad \text{and}
\]

\[
\lim_{k \to +\infty} \frac{1}{k} \sum_{j=0}^{k-1} r_F(T_F^j x) = E_{m_F}(r_F|\mathcal{F})(x)
\]

for \( m \)-a.e. \( x \in F \). Here we have used the fact that \( r_F \in L^1(F, \mathcal{B}|F, m_F) \), which follows directly from Lemma 2.10(ii). Taking quotient we get

\[
\lim_{k \to +\infty} \frac{1}{n_k} \sum_{j=0}^{k-1} G(T_F^j x) = E_{m_F}(G|\mathcal{F})(x)/E_{m_F}(r_F|\mathcal{F})(x)
\]

for \( m \)-a.e. \( x \in F \). Combining this with (2.6) yields (2.5). \( \square \)

2.4. **Oseledets’ multiplicative ergodic theorem.** Recall that the angle \( \angle(x, y) \in [0, \pi/2] \) between two vectors \( x, y \in \mathbb{R}^d \setminus \{0\} \) is defined by

\[
\sin \angle(x, y) = \frac{(\|x\|^2\|y\|^2 - \langle x, y \rangle^2)^{1/2}}{\|x\|\|y\|},
\]

where \( \langle \cdot, \cdot \rangle \) is the standard inner product in \( \mathbb{R}^d \). Similarly the angle between linear subspaces \( U, V \) of \( \mathbb{R}^d \) is defined by

\[
\sin \angle(U, V) = \inf_{x \in U \setminus \{0\}, y \in V \setminus \{0\}} \sin \angle(x, y).
\]
Let $T$ be an invertible measure-preserving transformation of the Lebesgue space $(X, \mathcal{B}, m)$. We will require the following version of Oseledets’ multiplicative ergodic theorem, due to Froyland et al. [32, Theorem 4.1]:

**Theorem 2.12.** Let $M : X \to \mathbb{R}^{d \times d}$ be a measurable function such that

$$
\int \log^+ \|M(x)\| \, dm(x) < \infty.
$$

Then there exists a measurable set $X' \subseteq X$ with $T(X') = X'$ and $m(X') = 1$, such that for each $x \in X'$, there are positive integers $s(x), k_1(x), \ldots, k_{s(x)}(x)$ with $k_1(x) + \cdots + k_{s(x)}(x) = d$, numbers $\lambda_1(x) > \cdots > \lambda_{s(x)}(x) \geq -\infty$ and a splitting $\mathbb{R}^d = E^1_x \oplus \cdots \oplus E^s_x$ so that the following hold.

(i) $\dim E^i_x = k_i(x)$.

(ii) $M(x)E^i_x \subseteq E^i_{Tx}$ (with equality if $\lambda_i(x) > -\infty$).

(iii) For $1 \leq i \leq s(x)$ and $v \in E^i_x \setminus \{0\}$,

$$
\lim_{n \to \infty} \frac{1}{n} \log \|M(T^{-1}x) \cdots M(T^{-n}x)v\| = \lambda_i(x),
$$

with uniform convergence on any compact subset of $E^i_x \setminus \{0\}$.

(iv) For $1 \leq i \leq s(x)$,

$$
\lim_{n \to \infty} \max_{v \in E^i_{T^{-n}x}, \|v\|=1} \log \|M(T^{-1}x) \cdots M(T^{-n}x)v\| = \lambda_i(x).
$$

(v) $\lim_{n \to \pm \infty} \frac{1}{n} \log \angle(\oplus_{i \in I} E^i_{T^{-n}x}, \oplus_{j \in J} E^j_{T^{-n}x}) = 0$ whenever $I \cap J = \emptyset$.

(vi) The function $s : X' \to \mathbb{N}$ is measurable and $T$-invariant.

(vii) The mappings $x \mapsto \lambda_i(x), E^i_x, k_i(x)$ are measurable on $\{x : s(x) \geq i\}$, and $\lambda_i(Tx) = \lambda_i(x), k_i(Tx) = k_i(x)$.

**Remark 2.13.** (1) Theorem 2.12 is only stated in [32] for the case when $m$ is ergodic. It extends directly to the general case by using ergodic decomposition. When $M(x)$ is invertible for all $x$ this is the classic Oseledets’ multiplicative ergodic theorem, but we emphasize that the above is valid even in the non-invertible case (in which case the usual statements of Oseledets’ theorem only provide a flag and not a splitting).

(2) The uniform convergence in part (iii) of Theorem 2.12 is not stated in [32]. However it is well-known when $A$ takes values in $GL(\mathbb{R}, d)$, and the argument works also in the general case of $\mathbb{R}^{d \times d}$-valued cocycles. See e.g. [30, p. 1111] for a sketched proof. Part (iv) of Theorem 2.12 was only implicitly included in the proof of [32, Theorem 4.1].

(3) The numbers $\lambda_1(x), \ldots, \lambda_{s(x)}(x)$ are called the Lyapunov exponents of $M$ at $x$ with respect to $m$. The number $k_i(x)$ is called the multiplicity of $\lambda_i(x)$. Moreover, $\{(\lambda_i(x), k_i(x))\}_{1 \leq i \leq s(x)}$ is called the Lyapunov spectrum of $(M, m)$ over $X'$. 

17
The decomposition \( \bigoplus_{i=1}^{s(x)} E_x^i \) is called the Oseledets splitting of \( \mathbb{R}^d \), and \( E_x^i \), \( 1 \leq i \leq s(x) \), are called the Oseledets subspaces.

3. Canonical coding maps for average contracting affine IFSs

In this section, we prove the following proposition, which will be used in the proof of our main result.

**Proposition 3.1.** Let \( S = \{ S_j(x) = M_jx + a_j \}_{j \in \Lambda} \) be an affine IFS on \( \mathbb{R}^d \) and \( m \in \mathcal{M}(\Sigma) \). Suppose that \( S \) is average contracting with respect to \( m \). Let \( \pi : \Sigma \to \mathbb{R}^d \) be given by (1.2). Then there exists a Borel set \( E \subset \Sigma \) with \( \sigma(E) = E \) and \( m(E) = 1 \) such that for any \( x = (x_n)_{n=-\infty}^{\infty} \in E \),

(i) \( \pi(x) \) is well-defined, i.e. the limit in defining \( \pi(x) \) in (1.2) exists and is finite.

(ii) \( S_{x_0}(\pi \sigma^n x) = \pi(x) \).

(iii) \( \lim_{n \to \infty} \frac{1}{n} \log^+ \| \pi(\sigma^n x) \| = 0 \), where \( \log^+ z = \max\{0, \log z\} \).

Part (i) of the above proposition was first proved by Brandt [15] in the special case when \( m \) is a Bernoulli product measure, and it was then extended by Bougerol and Picard [14] to the general case when \( m \) is ergodic. For the convenience of the reader, we shall provide a self-contained proof of part (i).

Before proving Proposition 3.1, we shall first prove the following auxiliary result, which is a variant of Proposition 2.1 in [29].

**Proposition 3.2.** Let \( T : X \to X \) be an ergodic measure-preserving transformation on a probability space \( (X, B, m) \). Let \( \{ f_n \}_{n=1}^\infty \) be a sequence of non-negative measurable functions on \( X \) such that \( \log^+ f_1 \in L^1(m) \) and

\[
(3.1) \quad f_{n+k}(x) \leq f_n(x) f_k(T^n x)
\]

for all \( n, k \in \mathbb{N} \) and \( x \in X \). Set \( \lambda = \lim_{n \to \infty} (1/n) \int \log f_n \ dm \). Then for any \( \epsilon > 0 \), the following properties hold:

(i) If \( \lambda \neq -\infty \), then for \( m \)-a.e. \( x \in X \), there exists a positive integer \( n_0(x) \) such that

\[
(3.2) \quad | \log f_n(T^k x) - n\lambda | \leq (n + k)\epsilon
\]

for all \( n \geq n_0(x) \) and \( k \in \mathbb{N} \).

(ii) If \( \lambda = -\infty \), then for any \( N > 0 \) and \( m \)-a.e. \( x \in X \), there exists a positive integer \( n_0(x) \) such that

\[
(3.3) \quad \log f_n(T^k x) \leq -Nn + (n + k)\epsilon
\]

for all \( n \geq n_0(x) \) and \( k \in \mathbb{N} \).

**Proof.** Here we modify the arguments of [29, Proposition 2.1]. We only prove (i). The proof of (ii) is similar.

Assume that \( \lambda \in \mathbb{R} \). Let \( \epsilon > 0 \) and take \( 0 < \delta < \epsilon/5 \). By the Kingman’s sub-additive ergodic theorem, for \( m \)-a.e. \( x \in X \) there exists \( n_0(x) \) such that

\[
| \log f_n(x) - n\lambda | \leq n\delta
\]
for all $n \geq n_0(x)$ and,

$$| \log f_k(x) - k\lambda | \leq (n_0(x) + k)\delta$$

for all $k \in \mathbb{N}$. Hence by (3.1), for $n \geq n_0(x)$ and $k \in \mathbb{N}$,

$$\log f_n(T^k x) \geq \log f_{n+k}(x) - \log f_k(x)$$

(3.4)

$$\geq (n+k)(\lambda - \delta) - k\lambda - (n_0(x) + k)\delta$$

$$\geq n\lambda - 2(n+k)\delta \geq n\lambda - (n+k)\epsilon.$$

To see the opposite inequality, take $\ell$ large enough such that $|\beta - \lambda| < \delta$, where

$$\beta := \frac{1}{\ell} \int \log f_\ell \, dm.$$

Applying the Birkhoff ergodic theorem to the functions $\log f_j$ ($j = 1, \ldots, 2\ell$), we obtain

(3.5)

$$\lim_{p \to \infty} \frac{1}{p} \log f_j(T^p x) = 0 \quad \text{for } 1 \leq j \leq 2\ell \text{ and } m\text{-a.e. } x.$$

Let $n \geq 2\ell$, and $x \in X$. Write $n = q\ell + s$ with $\ell \leq s \leq 2\ell - 1$. By submultiplicativity, we have

$$f_n(x) \leq f_j(x) \left( \prod_{p=0}^{q-1} f_\ell(T^{p\ell+j} x) \right) f_{s-j}(T^{q\ell+j} x), \quad j = 0, 1, \ldots, \ell - 1,$$

where we take the convention that $f_0 \equiv 1$. Taking product of these inequalities yields

$$(f_n(x))^{\ell} \leq \left( \prod_{j=0}^{\ell-1} f_j(x) \right) \left( \prod_{p=0}^{q-1} f_\ell(T^p x) \right) \left( \prod_{j=0}^{\ell-1} f_{s-j}(T^{q\ell+j} x) \right),$$

so for $k \geq 0$,

$$(f_n(T^k x))^{\ell} \leq \left( \prod_{j=0}^{\ell-1} f_j(T^k x) \right) \left( \prod_{p=0}^{q\ell+k-1} f_\ell(T^p x) \right) \left( \prod_{j=0}^{\ell-1} f_{s-j}(T^{q\ell+k+j} x) \right).$$

Taking logarithm and dividing both sides by $\ell$ we have

(3.6) \quad \log(f_n(T^k x)) \leq \left( \sum_{i=0}^{n+k-s-1} \frac{1}{\ell} \log f_\ell(T^i x) \right) - \left( \sum_{i=0}^{k-1} \frac{1}{\ell} \log f_\ell(T^i x) \right) + \Lambda_1 + \Lambda_2,$

where $\Lambda_1 := \sum_{j=0}^{\ell-1} \frac{1}{\ell} \log f_j(T^k x)$, $\Lambda_2 := \sum_{j=0}^{\ell-1} \frac{1}{\ell} \log f_{s-j}(T^{q\ell+k+j} x)$.

Applying the Birkhoff ergodic theorem to the function $\frac{1}{\ell} \log f_\ell$, and combining it with (3.5)-(3.6), we see that for $m$-a.e. $x \in X$, there exists an integer $\tilde{n}_0(x)$ such that

$$\log f_n(T^k x) \leq (n + k)(\beta + \delta) - k(\beta - \delta) + k\delta + (n + k)\delta + \tilde{n}_0(x)\delta$$

$$\leq n\beta + (2n + 4k + \tilde{n}_0(x))\delta \leq n\lambda + 5(n + k)\delta$$

$$\leq n\lambda + (n + k)\epsilon.$$
for all \( n \geq \tilde{n}_0(x) \) and \( k \in \mathbb{N} \). This together with (3.4) yields (3.2).

As a direct corollary of Proposition 3.2, we have the following.

**Corollary 3.3.** Under the assumptions of Proposition 3.2, for any \( \epsilon, N > 0 \) and for \( m \)-a.e. \( x \in X \), there exists \( c(x) > 0 \) such that
\[
|f_n(T^k x)| \leq c(x) \exp(n \max\{\lambda, -N\}) \exp((n + k)\epsilon)
\]
for all \( n, k \in \mathbb{N} \).

**Proof of Proposition 3.1.** Without loss of generality we may assume that \( m \) is ergodic, since the general case can be proved by considering the ergodic decomposition of \( m \).

Set \( f_n(x) = \|M_x \cdots M_{x_{n-1}}\| \) for \( x \in \Sigma \) and \( n \geq 1 \). Let \( f_0(x) \equiv 1 \) for convention. Since \( S \) is average contracting with respect to \( m \), we have
\[
\lim_{n \to \infty} \frac{1}{n} \int \log f_n \ dm =: \lambda < 0.
\]

Let \( 0 < \epsilon < -\lambda/3 \). Applying Corollary 3.3 to \( \{f_n\} \) and the shift map \( \sigma : \Sigma \to \Sigma \) (in which we take \( N = 2\epsilon \)), we see that for \( m \)-a.e. \( x \), there exists \( c(x) > 0 \) such that
\[
f_n(\sigma^k x) \leq c(x) e^{-2n\epsilon} (1 + k)\epsilon
\]
for any \( n \geq 1 \) and \( k \geq 0 \). It follows that for \( m \)-a.e. \( x \),
\[
\sum_{n=0}^{\infty} \|M_{x_k} \cdots M_{x_{k+n-1}} a_{x_{k+n}}\| \leq (\max_i \|a_i\|) \sum_{n=0}^{\infty} f_n(\sigma^k x)
\]
\[
\leq (\max_i \|a_i\|) c(x) \sum_{n=0}^{\infty} e^{-2n\epsilon} (1 + k)\epsilon
\]
\[
= (\max_i \|a_i\|) c(x) (1 - e^{-\epsilon})^{-1} e^{k\epsilon}
\]
for all \( k \geq 0 \). It follows that for \( m \)-a.e. \( x \), \( \pi(\sigma^k x) \) is well-defined and \( \|\pi(\sigma^k x)\| \leq (\max_i \|a_i\|) c(x) (1 - e^{-\epsilon})^{-1} e^{k\epsilon} \) for all \( k \geq 0 \). That is enough to conclude the proposition. \( \square \)

4. **Measurable partitions associated with affine IFSs**

Let \( S = \{M_j x + a_j\}_{j \in \Lambda} \) be an affine IFS on \( \mathbb{R}^d \) and \( m \in M_\sigma(\Sigma) \). Suppose that \( S \) is average contracting with respect to \( m \). In this section, under an additional assumption formulated later in (4.7), we construct a finite family of measurable partitions of \( \Sigma \) and give some properties of these partitions and the corresponding conditional measures of \( m \).

Define \( M : \Sigma \to \mathbb{R}^{d \times d} \) by
\[
M(x) = M_{x_{-1}}, \quad x = (x_n)_{n=-\infty}^{\infty}.
\]
Applying Theorem 2.12 to the measure-preserving system \((\Sigma, \sigma^{-1}, m)\) and the matrix cocycle \(M\), we get a measurable \(\Sigma' \subset \Sigma\) with \(\sigma(\Sigma') = \Sigma'\) and \(m(\Sigma') = 1\), so that the Lyapunov spectrum
\[
\{ (\lambda_i(x), k_i(x)) \}_{1 \leq i \leq s(x)}
\]
and the Oseledets splitting
\[
\mathbb{R}^d = E^1_x \oplus \cdots \oplus E^s_x(x)
\]
are well-defined for \(x \in \Sigma'\) (cf. Remark 2.13). In this case, for any \(x \in \Sigma'\) and \(1 \leq i \leq s(x)\),

\[
\lim_{n \to \infty} \frac{1}{n} \log \| M_{x-n} \cdots M_{x-1} v \| = \lambda_i(x) \quad \text{for } v \in E^i_x \setminus \{0\},
\]

with uniform convergence on any compact subset of \(E^i_x \setminus \{0\}\),

\[
\lim_{n \to \infty} \frac{1}{n} \max_{v \in E^i_{\sigma^n x}, \|v\|=1} \log \| M_{x-0} \cdots M_{x_{n-1}} v \|
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \min_{v \in E^i_{\sigma^n x}, \|v\|=1} \log \| M_{x-0} \cdots M_{x_{n-1}} v \| = \lambda_i(x),
\]

and

\[
\limsup_{n \to \infty} \frac{1}{n} \max_{v \in \oplus^{s(x)}_{j=0} E^j_{\sigma^n x}, \|v\|=1} \log \| M_{x-0} \cdots M_{x_{n-1}} v \| \leq \lambda_i(x).
\]

In addition, by Proposition 3.1 we may assume that the coding map \(\pi\) is well-defined on \(\Sigma'\) and that

\[
\lim_{n \to \infty} \frac{1}{n} \log^+ \| \pi(\sigma^n x) \| = 0 \quad \text{for } x \in \Sigma'.
\]

Define for \(x \in \Sigma'\),

\[
V^i_x := \oplus_{j=i+1}^{s(x)} E^j_x \quad \text{for } i = 0, \ldots, s(x) - 1, \quad \text{and} \quad V^{s(x)}_x := \{0\}.
\]

By (4.1), we have

\[
V^i_x = \left\{ v \in \mathbb{R}^d : \limsup_{n \to \infty} \frac{1}{n} \log \| M_{x-n} \cdots M_{x-1} v \| \leq \lambda_{i+1}(x) \right\}
\]

for \(x \in \Sigma', i = 0, \ldots, s(x) - 1\).

For \(x = (x_j)_{j=-\infty}^\infty \in \Sigma\), we write \(x^{-} = (x_j)_{j=-\infty}^{-1}\). The following simple fact is our starting point in constructing measurable partitions of \(\Sigma'\).

**Lemma 4.1.** Let \(x, y \in \Sigma'\) with \(x^{-} = y^{-}\). Then \(s(x) = s(y)\) and \(\lambda_i(x) = \lambda_i(y)\) for \(1 \leq i \leq s(x)\). Moreover, \(V^i_x = V^i_y\) for \(0 \leq i \leq s(x)\).

**Proof.** For \(x \in \Sigma'\) and \(v \in \mathbb{R}^d \setminus \{0\}\), define

\[
\lambda(x, v) := \lim_{n \to \infty} \frac{1}{n} \log \| M_{x-n} \cdots M_{x-1} v \|.
\]
By (4.1), the above limit always exists and takes values in \( \{ \lambda_i(x) : 1 \leq i \leq s(x) \} \). Clearly \( \lambda(x, v) \) only depends on \( v \) and \( x^- \). Hence for \( x, y \in \Sigma' \) with \( x^- = y^- \), we have \( s(x) = s(y) \) and \( \lambda_i(x) = \lambda_i(y) \) for \( 1 \leq i \leq s(x) \); by (4.6) we also have \( V_x^i = V_y^i \) for \( 1 \leq i \leq s(x) \). This completes the proof of the lemma.

In the remaining part of this section, we always make the following assumption:

\[(4.7) \quad s(x), k_1(x), \ldots, k_{s(x)}(x) \text{ are constant for } m\text{-a.e. } x \in \Sigma'. \]

Here we don’t make the stronger assumption that \( m \) is ergodic. Let us write these constants as \( s, k_1, \ldots, k_s \).

Below we construct a finite family of measurable partitions \( \xi_0, \ldots, \xi_s \) of \( \Sigma' \).

Let \( \xi_0 \) be the partition of \( \Sigma' \) so that the \( \xi_0 \)-atom containing \( x = (x_j)_{j=-\infty}^{+\infty} \in \Sigma' \) is given by

\[ \xi_0(x) = \{ y = (y_j)_{j=-\infty}^{+\infty} \in \Sigma' : y_j = x_j \text{ for } j \leq -1 \}. \]

By Lemma 4.1, \( V_y^i = V_x^i \) for any \( y \in \xi_0(x) \) and \( i \in \{0, 1, \ldots, s\} \).

Similarly, for \( i \in \{1, \ldots, s\} \), we define the partition \( \xi_i \) of \( \Sigma' \) by

\[ \xi_i(x) = \{ y = (y_j)_{j=-\infty}^{+\infty} \in \xi_0(x) : \pi y - \pi x \in V_x^i \}, \quad x \in \Sigma'. \]

**Lemma 4.2.** \( \xi_0, \ldots, \xi_s \) are measurable partitions of \( (\Sigma', \mathcal{B}(\Sigma'), m) \).

**Proof.** By Rohlin theory (cf. [60, Section 2.5], [52, Chapter IV]), it is enough to show that for every \( i \in \{0, 1, \ldots, s\} \), one can construct a measurable mapping \( \pi_i \) from \( \Sigma' \) to a complete separable metric space \( Y_i \) such that \( \xi_i \) is induced by \( \pi_i \), in the sense that \( \xi_i = \{ \pi_i^{-1}(y) : y \in Y_i \} \). Below we construct such mappings \( \pi_i \).

Let \( \Sigma^- := \{ (x_n)_{n=-\infty}^{-1} : x_n \in \Lambda \text{ for all } n \leq -1 \} \) and endow it with a suitable metric compatible to the discrete product topology. For \( j \in \{0, \ldots, d\} \), the set of all \( j \)-dimensional affine subspaces in \( \mathbb{R}^d \) forms a closed smooth manifold, which is called the \((d, j)\)-affine Grassmannian and is denoted by \( \text{Graff}(d, j) \).

Set \( Y_i = \Sigma^- \times \text{Graff}(d, k_{i+1} + \cdots + k_s) \) for \( i \in \{0, \ldots, s - 1\} \) and \( Y_s = \Sigma^- \times \mathbb{R}^d \).

Define \( \pi_i : \Sigma' \to Y_i \) \( (i = 0, 1, \ldots, s) \) by

\[ x \mapsto (x^-, V_x^i + \pi x). \]

It is readily checked that for each \( i \), \( \pi_i \) is measurable and \( \xi_i \) is induced by \( \pi_i \). \( \square \)

**Remark 4.3.** The above construction of the measurable partitions \( \xi_0, \ldots, \xi_s \) is different from that built in the previous work of [28, 4]. In [28], the partitions were made on the one-sided shift space due to the simple structure of Oseledets splitting subspaces. In [4], the partitions were made on the product space of the self-affine set and the flag manifolds.

Let \( \mathcal{P} \) be the canonical partition of \( \Sigma' \) given in (1.4). For \( n \in \mathbb{N} \), set

\[ \mathcal{P}^{n-1}_0 = \bigvee_{j=0}^{n-1} \sigma^{-j} \mathcal{P}, \]

where \( \bigvee \) stands for the join of partitions (cf. [53]).
For convenience, write

\[(4.8) \quad Q_{n,\epsilon} := \{ x \in \Sigma' : \| \pi \sigma^j x \| \leq (1/2)e^{j\epsilon/2} \text{ for all } j \geq n \}\]

for \( n \in \mathbb{N} \) and \( \epsilon > 0 \). Below we give several lemmas to further illustrate the properties of \( \xi_i \) and the associated conditional measures.

**Lemma 4.4.**

1. For \( x \in \Sigma', \ i \in \{0, \ldots, s\} \) and \( n \in \mathbb{N} \),

\[ \xi_i(x) \cap P_n^{-1}(x) = \sigma^{-n}(\xi_i(\sigma^n x)). \]

As a consequence, \( \xi_i \cap P_n^{-1} = (\sigma^{-n} \xi_i) \cap P_n^{-1} = \sigma^{-n} \xi_i \).

2. Let \( x \in \Sigma' \) and \( \epsilon > 0 \). Then for \( i \in \{0, \ldots, s - 1\} \),

\[(4.9) \quad Q_{n,\epsilon} \cap \xi_i(x) \cap P_n^{-1}(x) \subset \begin{cases} B^\pi(x, e^{n(\lambda_{i+1}(x)+2\epsilon)}) & \text{if } \lambda_{i+1}(x) \neq -\infty \\ B^\pi(x, e^{-n/\epsilon}) & \text{if } \lambda_{i+1}(x) = -\infty \end{cases} \]

when \( n \) is large enough, here \( B^\pi(x, r) \) is defined as in (2.3). Moreover,

\[(4.10) \quad Q_{n,\epsilon} \cap P_n^{-1}(x) \subset \begin{cases} B^\pi(x, e^{n(\lambda_1(x)+2\epsilon)}) & \text{if } \lambda_1(x) \neq -\infty \\ B^\pi(x, e^{-n/\epsilon}) & \text{if } \lambda_1(x) = -\infty \end{cases} \]

when \( n \) is large enough.

**Proof.** We first prove (1). Let \( x = (x_j)_{j=\infty}^{-\infty} \in \Sigma' \), \( \ i \in \{0, \ldots, s\} \) and \( n \in \mathbb{N} \). We only prove that \( \xi_i(x) \cap P_n^{-1}(x) \subset \sigma^{-n}(\xi_i(\sigma^n x)) \). The proof of the other direction is similar.

Let \( y = (y_j)_{j=\infty}^{-\infty} \in \xi_i(x) \cap P_n^{-1}(x) \). Then \( \pi y - \pi x \in V_x^i \) and \( y_j = x_j \) for \( j \leq n - 1 \). By Proposition 3.1(ii),

\[(4.11) \quad \pi y - \pi x = S_{y_0 \cdots y_{n-1}}(\pi \sigma^n y) - S_{x_0 \cdots x_{n-1}}(\pi \sigma^n x) \]

\[= S_{x_0 \cdots x_{n-1}}(\pi \sigma^n y) - S_{x_0 \cdots x_{n-1}}(\pi \sigma^n x) \]

\[= M_{x_0 \cdots x_{n-1}}(\pi \sigma^n y - \pi \sigma^n x), \]

here and afterwards we write \( M_{i_1 \cdots i_n} \) for \( M_{i_1} \cdots M_{i_n} \). Since \( \pi y - \pi x \in V_x^i \), by (4.11) and (4.6) we have

\[
\lim_{k \to \infty} \frac{1}{n+k} \log \| M_{x_{k+1} \cdots x_{n-1}}(\pi \sigma^n y - \pi \sigma^n x) \| = \lim_{k \to \infty} \frac{1}{n+k} \log \| M_{x_{k+1} \cdots x_{n-1}}(\pi y - \pi x) \| \leq \lambda_{i+1}(x) = \lambda_{i+1}(\sigma^n x).
\]

Applying (4.6) to \( V_{\sigma^n x}^i \) gives \( \pi \sigma^n y - \pi \sigma^n x \in V_{\sigma^n x}^i \). In the meantime, since \( y_j = x_j \) for \( j \leq n - 1 \), we have also \( \sigma^n y \in \xi_0(\sigma^n x) \). Therefore \( y \in \sigma^{-n}(\xi_0(\sigma^n x)) \). This proves \( \xi_i(x) \cap P_n^{-1}(x) \subset \sigma^{-n}(\xi_i(\sigma^n x)) \).

Next we prove (2). Let \( x \in \Sigma', \ i \in \{0, \ldots, s - 1\} \) and \( \epsilon > 0 \). By (4.3) and (4.4), there exists \( n_0 \) such that for any \( n \geq n_0 \),

\[(4.12) \quad \max_{v \in V_{\sigma^n x}^i} \| M_{x_0 \cdots x_{n-1}} v \| \leq \begin{cases} e^{n(\lambda_{i+1}(x)+\epsilon)} & \text{if } \lambda_{i+1}(x) \neq -\infty \\ e^{-2n/\epsilon} & \text{if } \lambda_{i+1}(x) = -\infty \end{cases} \]
Lemma 4.5. Let $n \geq n_0$ and $y \in Q_n \cap \xi_i(x) \cap \mathcal{P}_0^{n-1}(x)$. Then $\|\pi \sigma^n y\| \leq (1/2)e^{n\epsilon/2}$, $y^- = x^-$, $\pi y - \pi x \in V^0_x$ and furthermore by (1), $\pi \sigma^n y - \pi \sigma^n x \in V^0_{\delta x}$. By (4.11)-(4.13),

\[
\|\pi y - \pi x\| = \|M_{x_0 \cdots x_{n-1}}(\pi \sigma^n y - \pi \sigma^n x)\| \\
\leq \left( \max_{v \in V^0_{\delta x}, \|v\|=1} \|M_{x_0 \cdots x_{n-1}} v\| \right) \|\pi \sigma^n y - \pi \sigma^n x\| \\
\leq \left\{ \begin{array}{ll}
e^n(\lambda_{i+1}(x)+2\epsilon) & \text{if } \lambda_{i+1}(x) \neq -\infty \\
e^{-n/\epsilon} & \text{if } \lambda_{i+1}(x) = -\infty. \end{array} \right.
\]

This proves (4.9). Moreover, since $V^0_x = \mathbb{R}^d$, the above argument for the case $i = 0$ actually proves (4.10). \qed

Recall that for a measurable partition $\eta$ of $\Sigma'$, \{$m^\eta_n\$} stands for the canonical system of conditional measures associated with $\eta$ (cf. Section 2.2).

**Lemma 4.5.** Let $i \in \{0, 1, \ldots, s\}$. Then for $m$-a.e. $x \in \Sigma'$, the following hold.

1. $m_x^{\sigma^{-n}\xi_i}(A) = m_{\sigma^n x}^{\xi_i}(\sigma^n A)$ for any $n \in \mathbb{N}$ and measurable $A \subset \Sigma'$.

2. $m_x^{\sigma^{-n}\xi_i}(A) = \frac{m_x^{\xi_i}(A \cap \mathcal{P}_0^{n-1}(x))}{m_x^{\xi_i}(\mathcal{P}_0^{n-1}(x))}$ for any $n \in \mathbb{N}$ and measurable $A \subset \Sigma'$.

3. $\frac{m_x^{\xi_i}(\sigma^{-n} A \cap \mathcal{P}_0^{n-1}(x))}{m_{\sigma^n x}^{\xi_i}(A)} = m_x^{\xi_i}(\mathcal{P}_0^{n-1}(x))$ for any $n \in \mathbb{N}$ and measurable $A \subset \Sigma'$.

**Proof.** All the results follow from the $\sigma$-invariance of $m$ and the uniqueness of conditional measures. For the reader’s convenience, we include below the detailed arguments.

To see (1), fix $n \in \mathbb{N}$ and define a family of probability measures \{$\mu_x\}_{x \in \Sigma'}$ such that $\mu_x$ is supported on $(\sigma^{-n}\xi_i)(x) = (\sigma^{-n}(\xi_i(\sigma^n x)))$ and satisfies

$\mu_x(A) = m_{\sigma^n x}^{\xi_i}(\sigma^n A)$ for any measurable $A \subset \Sigma'$.

Then by Theorem 2.4, for every measurable $A \subset \Sigma'$ and $m$-a.e. $x$,

$\mu_x(A) = E_m(\chi_{\sigma^n A} | \hat{\xi}_i)(\sigma^n x) \\
= E_m(\chi_{\sigma^n A} \circ \sigma^n | \sigma^{-n} \hat{\xi}_i)(x)$ \hspace{1em} (by Lemma 2.1(i))

$= E_m(\chi_A | \sigma^{-n} \hat{\xi}_i)(x)$.

It follows that $x \mapsto \mu_x(A)$ is $\sigma^{-n}\hat{\xi}_i$-measurable and $m(A) = \int \mu_x(A) dm(x)$. Therefore, \{$\mu_x\$} is a canonical system of conditional measures associated with $\sigma^{-n}\hat{\xi}_i$. By the uniqueness of conditional measures, we have $\mu_x = m_x^{\sigma^{-n}\xi_i}$ for $m$-a.e. $x$. This proves (1).
To see (2), let \( n \in \mathbb{N} \) and notice that \( \sigma^{-n}\xi_i = \xi_i \vee P_0^\sigma_{n-1}(x) \) by Lemma 4.4(1). Similar to the proof of (1), we define a family of probability measures \( \{ \nu_x \}_{x \in \Sigma'} \) such that \( \nu_x \) is supported on \( (\sigma^{-n}\xi_i)(x) = \xi_i(x) \cap P_0^\sigma_{n-1}(x) \) and satisfies

\[
\nu_x(A) = \frac{m_2^\xi(A \cap P_0^\sigma_{n-1}(x))}{m_2^\xi(P_0^\sigma_{n-1}(x))} \quad \text{for any measurable } A \subset \Sigma'.
\]

Then by Theorem 2.4, for every measurable \( A \subset \Sigma' \) and \( m \)-a.e. \( x \),

\[
(4.14) \quad \nu_x(A) = \sum_{B \in P_0^\sigma_{n-1}} \chi_B(x) \cdot h_B(x),
\]

where \( h_B := E_m(\chi_{A \cap B}|\hat{\xi}_i)/E_m(\chi_B|\hat{\xi}_i) \). Since \( h_B \) is \( \hat{\xi}_i \)-measurable, the mapping \( x \mapsto \nu_x(A) \) is \( \hat{\xi}_i \vee P_0^\sigma_{n-1} \)-measurable (i.e. \( \sigma^{-n}\hat{\xi}_i \)-measurable). Moreover by (4.14),

\[
\int \nu_x(A) \, dm(x) = \sum_{B \in P_0^\sigma_{n-1}} \int \chi_B h_B \, dm
\]

\[
= \sum_{B \in P_0^\sigma_{n-1}} \int E_m(\chi_B h_B|\hat{\xi}_i) \, dm
\]

\[
= \sum_{B \in P_0^\sigma_{n-1}} \int E_m(\chi_B \hat{\xi}_i) h_B \, dm
\]

\[
= \sum_{B \in P_0^\sigma_{n-1}} \int E_m(\chi_{A \cap B}|\hat{\xi}_i) \, dm
\]

\[
= \sum_{B \in P_0^\sigma_{n-1}} m(A \cap B) = m(A).
\]

Hence the family \( \{ \nu_x \} \) is a canonical system of conditional measures associated with \( \sigma^{-n}\xi_i \), and so (2) follows by the uniqueness of conditional measures.

Finally we prove (3). By (1), we have

\[
m_{\sigma_{n-1}}^\xi(A) = m_{\sigma_{n-2}}^\xi(\sigma(\sigma^{-n}A)) = m_x^{\sigma^{-n}\xi_i}(\sigma^{-n}A).
\]

Applying (2) to \( \sigma^{-n}A \) (instead of \( A \)) yields that

\[
m_{\sigma_{n-1}}^\xi(A) = m_x^{\sigma^{-n}\xi_i}(\sigma^{-n}A) = \frac{m_2^\xi(\sigma^{-n}A \cap P_0^\sigma_{n-1}(x))}{m_2^\xi(P_0^\sigma_{n-1}(x))},
\]

which implies (3). \( \square \)

Now for \( i \in \{ 0, 1, \ldots, s \} \), define

\[
(4.15) \quad h_i(x) = E_m(f_i|\mathcal{I})(x), \quad x \in \Sigma',
\]

where \( f_i := I_m(\mathcal{P}|\hat{\xi}_i) \) and \( \mathcal{I} = \{ A \in \mathcal{B}(\Sigma') : \sigma^{-1}A = A \} \). By Lemma 2.1(v), \( f_i \geq 0 \) a.e. and \( f_i \in L^1 \). It follows that \( h_i \geq 0 \) a.e. and \( h_i \in L^1 \).
Lemma 4.6. Let \( i \in \{0, 1, \ldots, s\} \). Then for \( m \)-a.e. \( x \in \Sigma' \),
\[
\log m_x^n(\mathcal{P}_0^{n-1}(x)) = - \sum_{j=0}^{n-1} I_m(\mathcal{P} | \xi_i)(\sigma^j x) \quad \text{and}
\]
\[
- \lim_{n \to \infty} \frac{1}{n} \log m_x^n(\mathcal{P}_0^{n-1}(x)) = h_i(x).
\]
Furthermore,
\[
- \lim_{n \to \infty} \frac{1}{n} \log m(\mathcal{P}_0^{n-1}(x)) = h_0(x) \quad \text{for} \ m \text{-a.e.} \ x \in \Sigma'.
\]

Proof. Let \( i \in \{0, 1, \ldots, s\} \). By Theorem 2.4,
\[
m_x^n(\mathcal{P}_0^{n-1}(x)) = \sum_{A \in \mathcal{P}_0^{n-1}} \chi_A(x)m_x^n(A) = \sum_{A \in \mathcal{P}_0^{n-1}} \chi_A(x)E_m(\chi_A | \xi_i)(x)
\]
and hence \( - \log m_x^n(\mathcal{P}_0^{n-1}(x)) = I_m(\mathcal{P}_0^{n-1} | \xi_i)(x) \) for \( m \)-a.e. \( x \). By Lemma 2.1,
\[
I_m(\mathcal{P}_0^{n-1} | \xi_i) = I_m(\mathcal{P} | \xi_i) + I_m \left( \bigvee_{j=1}^{n-1} \sigma^{-j}\mathcal{P} | \sigma^{-1} \xi_i \right)
\]
\[
= I_m(\mathcal{P} | \xi_i) + I_m \left( \bigvee_{j=1}^{n-1} \sigma^{-j}\mathcal{P} | \sigma^{-1} \xi_i \right) \quad \text{(by Lemma 4.4(1))}
\]
\[
= I_m(\mathcal{P} | \xi_i) + I_m(\mathcal{P}_0^{n-2} | \xi_i) \circ \sigma \quad \text{(by Lemma 2.1(ii))}.
\]
Therefore by induction we have
\[
I_m(\mathcal{P}_0^{n-1} | \xi_i) = \sum_{j=0}^{n-1} I_m(\mathcal{P} | \xi_i) \circ \sigma^j.
\]

Now (4.16) follows from (4.18) and the Birkhoff ergodic theorem.

To see (4.17), applying the Shannon-McMillian-Breiman theorem (see e.g. [53, p. 39]) to the transformations \( \sigma \) and \( \sigma^{-1} \) respectively, we have the following convergences (pointwise and in \( L^1 \)):
\[
- \lim_{n \to +\infty} \frac{1}{n} \log m(\mathcal{P}_0^{n-1}(x)) = E_m(g_1 | \mathcal{I})(x),
\]
\[
- \lim_{n \to +\infty} \frac{1}{n} \log m(\mathcal{P}_0^{n-1}(x)) = E_m(g_2 | \mathcal{I})(x),
\]
where \( g_1 := I_m(\mathcal{P} \bigvee_{j=1}^{\infty} \sigma^{-j} \tilde{\mathcal{P}}) \), \( g_2 := I_m(\mathcal{P} \bigvee_{j=1}^{\infty} \sigma^{-j} \tilde{\mathcal{P}}) \). Noticing that \( \tilde{\xi}_0 = \bigvee_{j=1}^{\infty} \sigma^j \tilde{\mathcal{P}} \),
we have \( g_2 = I_m(\mathcal{P} | \tilde{\xi}_0) = f_0 \) and so \( E_m(g_2 | \mathcal{I}) = h_0 \). To prove (4.17), by (4.19) it suffices to show that
\[
E_m(g_1 | \mathcal{I})(x) = E_m(g_2 | \mathcal{I})(x) \quad \text{for} \ m \text{-a.e.} \ x.
\]
To see (4.20) first observe that for $x \in \Sigma'$, $\mathcal{P}_{-(n-1)}^0(\sigma^n x) = \sigma^n(\mathcal{P}_{0}^{n-1}(x))$ and hence $m(\mathcal{P}_{-(n-1)}^0(\sigma^n x)) = m(\sigma^n(\mathcal{P}_{0}^{n-1}(x))) = m(\mathcal{P}_{0}^{n-1}(x))$. For any $B \in \mathcal{I}$, we have

$$
\int_B \log m(\mathcal{P}_{-(n-1)}^0(x)) \, dm(x) = \int \chi_B(x) \log m(\mathcal{P}_{-(n-1)}^0(x)) \, dm(x) = \int \chi_B(\sigma^n x) \log m(\mathcal{P}_{-(n-1)}^0(\sigma^n x)) \, dm(x) \quad \text{(by the \sigma-invariance of m)}
$$

Therefore $\mathbf{E}_m(g_1|\mathcal{I}) = \mathbf{E}_m(g_2|\mathcal{I})$ almost everywhere. This completes the proof of the lemma. \hfill \Box

Below we give an interesting corollary of Lemma 4.6, although we will not use it in the rest part of the paper.

**Corollary 4.7.** Let $i \in \{0,1,\ldots,s\}$. Then $h_i = 0$ a.e. if and only if $m_x^\xi_i(\{x\}) = 1$ for m-a.e. $x \in \Sigma'$.

**Proof.** By Lemma 2.1(v), $f_i := \mathbf{I}_m(\mathcal{P}|\hat{\xi}_i) \geq 0$ a.e. and $f_i \in L^1$. Hence by (4.15), $h_i = 0$ a.e. if and only if $f_i = 0$ a.e. However according to the first equality in (4.16), the condition $f_i = 0$ a.e. implies that for m-a.e. $x$, $m_x^\xi_i(\mathcal{P}_{0}^{n-1}(x)) = 1$ for every $n \geq 1$ and hence

$$
m_x^\xi_i(\{x\}) = m_x^\xi_i(\xi_0(x) \cap \mathcal{P}_{0}^{\infty}(x)) = m_x^\xi_i(\mathcal{P}_{0}^{\infty}(x)) = 1,
$$

using the fact that $m_x^\xi_i$ is supported on $\xi_i(x) \subset \xi_0(x)$. Conversely, by the first equality in (4.16) (applied to $n = 1$), we obtain that $f_i(x) = - \log m_x^\xi_i(\mathcal{P}(x))$; hence the condition $m_x^\xi_i(\{x\}) = 1$ a.e. implies that $f_i = 0$ a.e. This completes the proof of the corollary. \hfill \Box

We end the section by the following.

**Lemma 4.8.** Let $\epsilon > 0$ and define $Q_{n,\epsilon}$ as in (4.8) for $n \in \mathbb{N}$. Then for m-a.e. $x \in \Sigma'$,

$$
\lim_{n \to \infty} \frac{m_x^\xi_i(Q_{n,\epsilon} \cap \mathcal{P}_{0}^{n-1}(x))}{m_x^\xi_i(\mathcal{P}_{0}^{n-1}(x))} = 1 \quad (i = 0,1,\ldots,s)
$$
and
\[
\lim_{n \to \infty} \frac{m(Q_{n, \epsilon} \cap P_{0}^{n-1}(x))}{m(P_{0}^{n-1}(x))} = 1.
\]

Proof. The equalities follow from the Borel density lemma and the facts that the sequence \((Q_{n, \epsilon})\) of sets is monotone increasing as \(n\) increases, and \(\bigcup_n Q_{n, \epsilon}\) is of full \(m\)-measure by Proposition 3.1(iii).

\[ \Box \]

5. Transverse dimensions

In this section, we prove an inequality for the transverse dimensions of the conditional measures that we constructed in Section 4.

Recall that \(S\) is an affine IFS on \(R^d\) of the form (1.1), average contracting with respect to some \(m \in M_\sigma(\Sigma)\). Let \(\pi\) be the associated coding map. Suppose that \(H_m(\mathcal{P}) < \infty\), where \(\mathcal{P}\) is defined as in (1.4). Let \(M : \Sigma \to R^{d \times d}\) be the matrix cocycle given by \(M(x) = M_{x-1}\), and \(\{((\lambda_i(x), k_i(x)))\}_{1 \leq i \leq s(x), x \in \Sigma}^s\) the Lyapunov spectrum for \(M\) with respect to the transformation \(\sigma^{-1}\). Suppose that (4.7) holds, i.e. there exist \(s, k_1, \ldots, k_s\) so that \(s(x) = s, k_i(x) = k_i (i = 1, \ldots, s)\) for \(m\)-a.e. \(x \in \Sigma\). Let \(E_x^i\) be the Oseledets splitting of \(R^d\), and \(\{0\} = V_x^s \subset \cdots \subset V_x^0 = R^d\) the associated filtration.

Let \(\xi_0, \xi_1, \ldots, \xi_s\) be the measurable partitions of \(\Sigma'\) that we constructed in Section 4. For \(x \in \Sigma'\) and \(r > 0\), set
\[
\Gamma_i(x, r) = \{y \in \Sigma' : \text{dist}(\pi y + V_x^i, \pi x + V_x^i) \leq r\}, \quad i = 1, \ldots, s
\]
and define
\[
\vartheta_{i-1}(x) = \liminf_{r \to 0} \frac{\log m_x^{\xi_i}(\Gamma_i(x, r))}{\log r}, \quad i = 1, \ldots, s.
\]
We call \(\vartheta_0, \ldots, \vartheta_{s-1}\) the transverse dimensions of \(m\). Intuitively we may view \(\vartheta_i(x)\) as the dimension of \(m\) along the direction \(E_x^{i+1}\).

The main result of this section is the following, which plays a key role in the proof of Theorem 1.2.

Proposition 5.1. For \(m\text{-a.e. } x \in \Sigma'\),
\[
\vartheta_{i-1}(x) \geq \frac{h_i(x) - h_{i-1}(x)}{\lambda_i(x)}, \quad i = 1, \ldots, s,
\]
where \(h_i\) are defined as in (4.15).

This result can be viewed as an analogue of Proposition 11.2 in [44]. A stronger version of the result, with the inequality being replaced by the equality, was proved earlier in [28, Theorem 6.2], [2, Theorem 3.3], and [4, Propositions 5.3 and 7.3] under various additional assumptions.

The proof of Proposition 5.1 is quite long and delicate. Besides extending some ideas from the previous works [44, 28, 4], we need to employ certain new strategy as well.
We first introduce some notation and give several lemmas.

For \( x \in \Sigma', \, i \in \{1, \ldots, s\} \) and \( r > 0 \), set
\[
B^i_x(r) = \{ v \in E^i_x : \| v \| \leq r \}
\]
and
\[
T^i(x, r) = \{ y \in \xi_{i-1}(x) : \pi y - \pi x \in V^i_x \oplus B^i_x(r) \}.
\]

**Lemma 5.2.** Let \( x \in \Sigma', \, i \in \{1, \ldots, s\}, \, n \in \mathbb{N} \) and \( r > 0 \). For
\[
0 \leq a \leq \min_{v \in E^i_{x_n,x}, \| v \| = 1} \| M_{x_0 \ldots x_{n-1}} v \|
\]
we have
\[
T^i(x, ar) \cap \mathcal{P}_0^{n-1}(x) \subset \sigma^{-n} T^i(\sigma^n x, r).
\]

**Proof.** Let \( y \in T^i(x, ar) \cap \mathcal{P}_0^{n-1}(x) \). By definition,
\[
y \in \xi_{i-1}(x) \cap \mathcal{P}_0^{n-1}(x) \quad \text{and} \quad \pi y - \pi x \in V^i_x \oplus B^i_x(ar).
\]
By (5.3) and Lemma 4.4(1), \( y \in \sigma^{-n}(\xi_{i-1}(\sigma^n x)) \). Moreover since \( y \in \mathcal{P}_0^{n-1}(x) \), by (4.11),
\[
\pi y - \pi x = M_{x_0 \ldots x_{n-1}}(\pi \sigma^n y - \pi \sigma^n x).
\]
Since \( y \in \xi_{i-1}(x) \), by definition \( \pi y - \pi x \in V^{i-1}_x = V^i_x \oplus E^i_x \). Applying (4.6) to \( V^{i-1}_x \) yields
\[
\limsup_{k \to \infty} \frac{1}{k} \log \| M_{x_{-k} \ldots x_{-1}}(\pi y - \pi x) \| \leq \lambda_i(x) = \lambda_i(\sigma^n x),
\]
where the last equality follows from Theorem 2.12(vii). Hence by (5.5),
\[
\limsup_{k \to \infty} \frac{1}{n + k} \log \| M_{x_{-k} \ldots x_{-1} x_0 \ldots x_{n-1}}(\pi \sigma^n y - \pi \sigma^n x) \| \leq \lambda_i(\sigma^n x).
\]
Applying (4.6) to \( V^{i-1}_{\sigma^n x} \) gives \( \pi \sigma^n y - \pi \sigma^n x \in V^{i-1}_{\sigma^n x} = V^i_{\sigma^n x} \oplus E^i_{\sigma^n x} \). Write
\[
\pi y - \pi x = v_1 + w_1 \quad \text{with} \quad v_1 \in V^i_x \text{ and } w_1 \in E^i_x,
\]
\[
\pi \sigma^n y - \pi \sigma^n x = v_2 + w_2 \quad \text{with} \quad v_2 \in V^i_{\sigma^n x} \text{ and } w_2 \in E^i_{\sigma^n x}.
\]
By (5.4), \( w_1 \in B^i_x(ar) \) and hence \( \| w_1 \| \leq ar \). Since \( M_{x_0 \ldots x_{n-1}} V_{\sigma^n x}^i \subset V^i_x \) and \( M_{x_0 \ldots x_{n-1}} E_{\sigma^n x}^i \subset E^i_x \), by (5.5) we see that \( w_1 = M_{x_0 \ldots x_{n-1}} w_2 \) and so
\[
ar \geq \| w_1 \| = \| M_{x_0 \ldots x_{n-1}} w_2 \| \geq a \| w_2 \|.
\]
It follows that \( \| w_2 \| \leq r \). Hence \( \pi \sigma^n y - \pi \sigma^n x \in V^i_{\sigma^n x} \oplus B^i_{\sigma^n x}(r) \). This together with \( y \in \sigma^{-n}(\xi_{i-1}(\sigma^n x)) \) yields that \( y \in \sigma^{-n} T^i(\sigma^n x, r) \). Therefore
\[
T^i(x, ar) \cap \mathcal{P}_0^{n-1}(x) \subset \sigma^{-n} T^i(\sigma^n x, r)
\]
and we are done.  \( \Box \)
Let $\theta(x)$ denote the smallest angle between the Oseledets subspaces, i.e.

$$\theta(x) = \min_{I \cap J = \emptyset} \angle \left( \oplus_{i \in I} E_x^i, \oplus_{j \in J} E_x^j \right).$$

We have the following.

**Lemma 5.3.** For $x \in \Sigma'$, $i \in \{1, \ldots, s\}$ and $r > 0$,

$$T_i(x, r) \subset \xi_{i-1}(x) \cap \Gamma_i(x, r) \subset T_i(x, r/\sin \theta(x)).$$

**Proof.** We first prove that $T_i(x, r) \subset \xi_{i-1}(x) \cap \Gamma_i(x, r)$. Let $y \in T_i(x, r)$. Then by definition, $y \in \xi_{i-1}(x)$ and $\pi y - \pi x = v + w$ for some $v \in V_x^i$, $w \in E_x^i$ with $\|w\| \leq r$, which implies that

$$\text{dist}(\pi y, V_x^i, \pi x + V_x^i) \leq \|w\| \leq r.$$

Hence $y \in \xi_{i-1}(x) \cap \Gamma_i(x, r)$. This proves the relation $T_i(x, r) \subset \xi_{i-1}(x) \cap \Gamma_i(x, r)$.

Next we prove that $\xi_{i-1}(x) \cap \Gamma_i(x, r) \subset T_i(x, r/\sin(\theta(x)))$. Let $U_x^i := V_x^{i-1} \ominus V_x^i$ denote the orthogonal complement of $V_x^i$ in $V_x^{i-1}$. Let $z \in \xi_{i-1}(x) \cap \Gamma_i(x, r)$. Then $\pi z - \pi x \in V_x^{i-1}$ and $\pi x + V_x^i \leq \pi z + V_x^i$. Hence $\pi z - \pi x = v + u$ for some $v \in V_x^i$ and $u \in U_x^i$ with $\|u\| \leq r$. Since $v + u \in V_x^{i-1} = V_x^i \ominus E_x^i$, $v + u = v_1 + w_1$ for some $v_1 \in V_x^i$ and $w_1 \in E_x^i$. Notice that $w_1 = (v - v_1) + u$ with $u \perp (v - v_1)$. We have

$$\|w_1\| = \frac{\|u\|}{\sin \angle(w_1, v - v_1)} \leq \frac{\|u\|}{\sin \theta(x)} \leq \frac{r}{\sin \theta(x)}.$$ 

Thus $\pi z - \pi x = v_1 + w_1$, where $v_1 \in V_x^i$ and $w_1 \in E_x^i$ with $\|w_1\| \leq r/\sin \theta(x)$. Therefore, $z \in T_i(x, r/\sin \theta(x))$ and we are done. \hfill \Box

Now we turn back to the proof of Proposition 5.1. Clearly, to prove the proposition it is sufficient to show that for any $\epsilon > 0$, there exists $F(\epsilon) \subset \Sigma'$ so that

$$\vartheta_{i-1}(x) \geq \frac{h_{i-1}(x) - h_i(x)}{-\lambda_i(x) + \epsilon} \quad \text{for m-a.e. } x \in F(\epsilon) \text{ and } i \in \{1, \ldots, s\}.$$

and $\lim_{\epsilon \to 0} m(F(\epsilon)) = 1$.

Here and afterwards in this section, we may assume that $\lambda_s \neq -\infty$ a.e.; since Proposition 5.1 holds automatically when $i = s$ and $\lambda_s(x) = -\infty$.

We first construct $F(\epsilon)$ for $\epsilon > 0$. Set

$$F_0(\epsilon) := \{x \in \Sigma' : \sin \theta(x) > \epsilon\}.$$

By (4.2), there exist a large integer $N(\epsilon)$ and a Borel set $F(\epsilon) \subset F_0(\epsilon)$ with $m(F(\epsilon)) > (1 - \epsilon)m(F_0(\epsilon))$ so that for $i \in \{1, \ldots, s\}$,

$$\|M_{x_0 \ldots x_{n-1}} v\| \geq \epsilon^{-1} e^{n(\lambda(x) - \epsilon)} \|v\|$$

for $x \in F(\epsilon)$, $n \geq N(\epsilon)$ and $v \in E_{x_n}^i$. Clearly, $m(F(\epsilon)) \to 1$ as $\epsilon \to 0$.

In the remaining part of this section we prove (5.6) for the constructed $F(\cdot)$. From now on, we fix $\epsilon > 0$ and write simply $F = F(\epsilon)$ and $N = N(\epsilon)$. 

Let $\sigma_F : F \to F$ be the transformation induced by $\sigma^N$ on the set $F$ (cf. Section 2.3). That is, $\sigma_F(x) = \sigma^{r_F(x)}(x)$, where 

$$r_F(x) := \inf\{n \geq 1 : \sigma^n x \in F\}.$$ 

The map $\sigma_F$ is well-defined on $F$ up to a set of zero $m$-measure. Let $m_F$ be the Borel probability measure on $F$ defined by

$$m_F(D) = \frac{m(F \cap D)}{m(F)}$$

for any Borel set $D \subset F$.

Recall that $m_F$ is $\sigma_F$-invariant.

For $x \in F$, set

$$\ell(x) = N r_F(x)$$

and

$$\rho(i, x) = e^{\ell(x)(\lambda_i - \epsilon)}, \quad i = 1, \ldots, s.$$ 

Then we have

**Lemma 5.4.** For $x \in F$, $i \in \{1, \ldots, s\}$ and $r > 0$,

$$\xi_{i-1}(x) \cap \Gamma_i(x, \rho(i, x)r) \cap P_0^{\ell(x)-1}(x) \subset \sigma_F^{-1}(\Gamma_i(\sigma_F x, r) \cap \xi_{i-1}(\sigma_F x)).$$

**Proof.** Fix $x \in F$, $i \in \{1, \ldots, s\}$ and $r > 0$. Set $a = \epsilon^{-1} \rho(i, x)$. By (5.8),

$$a = \epsilon^{-1} e^{\ell(x)(\lambda_i - \epsilon)} \leq \inf\{\|M^{\ell(x)}(x)v\| : v \in E_{\sigma F x}, \|v\| = 1\},$$

where $M^n(x) := M_{x_0 \cdots x_{n-1}}$. Observe that

$$\xi_{i-1}(x) \cap \Gamma_i(x, \rho(i, x)r)$$

$$\subset T_i(x, \rho(i, x)r / \sin \theta(x)) \quad \text{(by Lemma 5.3)}$$

$$\subset T_i(x, \epsilon^{-1} \rho(i, x)r) \quad \text{(since $\sin \theta(x) \geq \epsilon$)}$$

$$= T_i(x, ar).$$

Hence

$$\xi_{i-1}(x) \cap \Gamma_i(x, \rho(i, x)r) \cap P_0^{\ell(x)-1}(x)$$

$$\subset T_i(x, ar) \cap P_0^{\ell(x)-1}(x)$$

$$\subset \sigma^{-\ell(x)} T_i(\sigma^\ell(x)x, r) \quad \text{(by (5.11) and Lemma 5.2)}$$

$$= \sigma_F^{-1} T_i(\sigma_F x, r)$$

$$\subset \sigma_F^{-1}(\Gamma_i(\sigma_F x, r) \cap \xi_{i-1}(\sigma_F x)) \quad \text{(by Lemma 5.3)}.$$ 

This completes the proof of the lemma. 

Now write

$$F_n := \{x \in F : r_F(x) = n\}, \quad n = 1, 2, \ldots.$$ 

Recall that $\{m_\xi\}$ is the canonical system of conditional measures associated with $\xi_i$, $i = 0, \ldots, s$. The following result is an induced version of Lemma 2.5.
Proposition 5.5. Let $i \in \{1, \ldots, s\}$. Then for $m$-a.e. $x \in F$,\footnote{\textcopyright 2000-2019, American Mathematical Society.}
\begin{equation}
\lim_{r \to 0} \log \frac{m_x^{\xi_{i-1}} \left( \Gamma_i(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (\Gamma_i(x, r))} = -\infty \sum_{k=1}^{\infty} \chi_{F_k}(x) \sum_{j=0}^{kN-1} I_m(\mathcal{P}|\tilde{\xi}_i)(\sigma^j x).
\end{equation}

Furthermore, set
\begin{equation}
g(x) = -\inf_{r > 0} \frac{m_x^{\xi_{i-1}} \left( \Gamma_i(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (\Gamma_i(x, r))}.
\end{equation}

Then $g \geq 0$ and $g \in L^1(F, \mathcal{B}|_F, m_F)$.

Proof. Fix $i \in \{1, \ldots, s\}$. Write $d_i = \sum_{j=i+1}^s k_j$. Define $\phi_i : \Sigma' \to Y_i := G(d, d_i) \times \mathbb{R}^d$ by
\begin{equation}
\phi_i(x) = (V_x, P_{(V_x)} - (\pi x)).
\end{equation}

Then $\phi_i$ is measurable. Moreover,
\begin{equation}
\xi_i(x) = \{ y \in \xi_0(x) : \phi_i(y) = \phi_i(x) \}, \quad x \in \Sigma'.
\end{equation}

Endow $Y_i$ with the following product metric $\rho_i$:
\begin{equation}
\rho_i((V, a), (W, b)) = \max\{|P_V - P_W|, |a - b|\}.
\end{equation}

It is not hard to see that $Y_i$ is a Besicovitch space. For $x \in \Sigma'$ and $r > 0$, set
\begin{equation}
B^{\phi_i}(x, r) := \{ y \in \Sigma' : \rho_i(\phi_i y, \phi_i x) \leq r \}.
\end{equation}

Then by definition,
\begin{equation}
\xi_0(x) \cap B^{\phi_i}(x, r) = \xi_0(x) \cap \Gamma_i(x, r), \quad x \in \Sigma', \quad r > 0.
\end{equation}

Hence for $x \in F$ and $r > 0$,
\begin{align}
\frac{m_x^{\xi_{i-1}} \left( \Gamma_i(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (\Gamma_i(x, r))} &= \frac{m_x^{\xi_{i-1}} \left( \xi_0(x) \cap \Gamma_i(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (\xi_0(x) \cap \Gamma_i(x, r))} \\
&= \frac{m_x^{\xi_{i-1}} \left( \xi_0(x) \cap B^{\phi_i}(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (\xi_0(x) \cap B^{\phi_i}(x, r))} \\
&= \frac{m_x^{\xi_{i-1}} \left( B^{\phi_i}(x, r) \cap \mathcal{P}_0^{\ell(x)-1}(x) \right)}{m_x^{\xi_{i-1}} (B^{\phi_i}(x, r))} \\
&= \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \chi_{F_k \cap A}(x) \frac{m_x^{\xi_{i-1}} \left( B^{\phi_i}(x, r) \cap A \right)}{m_x^{\xi_{i-1}} (B^{\phi_i}(x, r))}.
\end{align}
By (5.17) and applying Lemma 2.5(1) to \( \phi_i : \Sigma' \to Y_i \), we have for \( m \)-a.e. \( x \in F \),

\[
\lim_{r \to 0} \frac{m_x^{\xi_i-1} \left( \Gamma_i(x, r) \cap \mathcal{P}_0^{(x)}(x) \right)}{m_x^{\xi_i-1} \left( \Gamma_i(x, r) \right)}
\]

\[
= \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \sum_{\xi_{i(k)}}(A) \log E_m \left( \chi_A \left| \mathcal{P}_0^{kN-1}(x) \right. \right) \chi_i(x)
\]

\[
= \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \sum_{\xi_{i(k)}}(A) \log E_m \left( \chi_A \left| \mathcal{P}_0^{kN-1}(x) \right. \right) \chi_i(x)
\]

\[
= \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \chi_A(x) \log E_m \left( \chi_A \left| \mathcal{P}_0^{kN-1}(x) \right. \right) \chi_i(x)
\]

\[
= -\sum_{k=1}^{\infty} \chi_m(x) \sum_{A \in \mathcal{P}_0^{kN-1}} \chi_A(x) \log E_m \left( \chi_A \left| \mathcal{P}_0^{kN-1}(x) \right. \right) \chi_i(x)
\]

\[
= -\sum_{k=1}^{\infty} \chi_m(x) \sum_{A \in \mathcal{P}_0^{kN-1}} \chi_A(x) \log E_m \left( \chi_A \left| \mathcal{P}_0^{kN-1}(x) \right. \right) \chi_i(x)
\]

This proves (5.13).

Next we prove that \( g \in L^1(m_F) \). We mainly follow the arguments in [28, Lemma 3.3 and Proposition 3.5]. By Theorem 2.4, for any given \( C \in \xi_{i-1} \), the conditional measures \( m_x^{\xi_i-1} (x \in C) \) represent the same measure supported on \( C \), which we rewrite as \( m_C \). Fix \( C \in \xi_{i-1} \), \( k \in \mathbb{N} \) and \( A \in \mathcal{P}_0^{kN-1} \). We define measures \( \mu_C \) and \( \nu_C \) on \( Y_i \) by \( \mu_C(E) = m_C(\phi_i^{-1}E \cap A) \) and \( \nu_C(E) = m_C(\phi_i^{-1}E) \) for all \( E \in \mathcal{B}(Y_i) \). By the Hardy-Littlewood maximal inequality (see, e.g. Theorem 7.4 in [62]), there exists a positive constant \( a \) (which depends on \( Y_i \)) such that

\[
\mu_C \left\{ z \in Y_i : \inf_{r > 0} \frac{\mu_C(B(z, r))}{\nu_C(B(z, r))} < u \right\} \leq au \quad (u > 0).
\]

Hence for any \( u > 0 \),

\[
m_C \left( \left\{ x \in \Sigma' : \inf_{r > 0} \frac{m_C(\phi_i(x, r) \cap A)}{m_C(\phi_i(x, r))} < u \right\} \right) \leq au.
\]

Integrating \( C \) over \( \xi_{i-1} \), we obtain

\[
m \left( \left\{ x \in \Sigma' : \inf_{r > 0} \frac{m_x^{\xi_i-1}(\phi_i(x, r) \cap A)}{m_x^{\xi_i-1}(\phi_i(x, r))} < u \right\} \right) \leq au.
\]

Write \( g^A(x) = \inf_{r > 0} \frac{m_x^{\xi_i-1}(\phi_i(x, r) \cap A)}{m_x^{\xi_i-1}(\phi_i(x, r))} \). Then the above inequality can be rewritten as

\[
(5.18) \quad m(A \cap \{g^A < u\}) \leq au.
\]
Note that by (5.14) and (5.17), $g(x) = -\sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \chi_{F_k \cap A}(x) \log g^A(x)$. Since $g$ is non-negative,

$$\int g \, dm = \int_0^\infty m\{g > t\} \, dt$$

$$= \int_0^\infty \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} m(F_k \cap A \cap \{g^A < e^{-t}\}) \, dt$$

$$\leq \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} \int_0^\infty \min\{m(F_k \cap A), ae^{-t}\} \, dt \quad \text{(by (5.18))}$$

$$\leq \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} (-m(F_k \cap A) \log m(F_k \cap A) + m(F_k \cap A)(1 + \log a))$$

$$\leq 1 + \log a + \sum_{k=1}^{\infty} \sum_{A \in \mathcal{P}_0^{kN-1}} (-m(F_k \cap A) \log m(F_k \cap A))$$

$$\leq 1 + \log a + \sum_{k=1}^{\infty} m(F_k) \left[ \left( \sum_{A \in \mathcal{P}_0^{kN-1}} - \frac{m(F_k \cap A)}{m(F_k)} \log \frac{m(F_k \cap A)}{m(F_k)} \right) \right.$$ 

$$\left. + \log \frac{1}{m(F_k)} \right]$$

$$\leq 1 + \log a + \sum_{k=1}^{\infty} m(F_k) \left( kN \log(\#A) + \log \frac{1}{m(F_k)} \right)$$

$$< \infty \quad \text{(by Lemma 2.10(ii)-(iii)).}$$

This finishes the proof of the proposition. \qed

Finally we are ready to prove (5.6), the last step in the proof of Proposition 5.1.

**Proof of (5.6).** Fix $\epsilon > 0$ and write $F = F(\epsilon)$. Let $i \in \{1, \ldots, s\}$.

For $x \in F$ and $n \in \mathbb{N}$, define

$$\rho_n(i, x) = \prod_{k=0}^{n-1} \rho(i, \sigma_F^k x),$$

where $\sigma_F^k := (\sigma_F)^k$, and $\rho(i, x) = e^{\ell(x)(\lambda_i(x) - \epsilon)}$ (as defined in (5.9)). Moreover, write

$$H_n(x) := \log \frac{m_x^{\xi_{i-1}}(\Gamma_i(x, \rho_n(i, x)))}{m_{\sigma_F^x}^{\xi_{i-1}}(\Gamma_i(\sigma_F^x x, \rho_{n-1}(i, \sigma_F^x x)))},$$

$$G_n(x) := \log \frac{m_x^{\xi_{i-1}}(\Gamma_i(x, \rho_n(i, x)) \cap \mathcal{P}_0^{\ell(x)-1}(x))}{m_x^{\xi_{i-1}}(\Gamma_i(x, \rho_n(i, x)))}.$$

34
Then for m-a.e. \( x \in F \),

\[
H_n(x) + G_n(x) = \log \frac{m_x^{\xi_i-1} \left( \Gamma_i (x, \rho_n(i, x)) \cap \mathcal{P}_0^{(x)-1}(x) \right)}{m_x^{\xi_i-1} \left( \Gamma_i (\sigma_{FX}, \rho_{n-1}(i, \sigma_{FX})) \right)}
\]

\[
= \log \frac{m_x^{\xi_i-1} \left( \xi_i^{-1}(x) \cap \Gamma_i (x, \rho_n(i, x)) \cap \mathcal{P}_0^{(x)-1}(x) \right)}{m_x^{\xi_i-1} \left( \Gamma_i (\sigma_{FX}, \rho_{n-1}(i, \sigma_{FX})) \right)}
\]

\[
\leq \log \frac{m_x^{\xi_i-1} \left( \sigma_F^{-1} \Gamma_i (\sigma_{FX}, \rho_{n-1}(i, \sigma_{FX})) \cap \mathcal{P}_0^{(x)-1}(x) \right)}{m_x^{\xi_i-1} \left( \Gamma_i (\sigma_{FX}, \rho_{n-1}(i, \sigma_{FX})) \right)} \quad \text{(by (5.10))}
\]

\[
= \log m_x^{\xi_i-1} \left( \mathcal{P}_0^{(x)-1}(x) \right) \quad \text{(by Lemma 4.5(3))}
\]

\[
= - \sum_{k=1}^{\infty} \chi_{F_k}(x) \sum_{j=0}^{kN-1} I_m(\mathcal{P}|\tilde{x}_i^{-1})(\sigma^j x) =: Q_{i-1}(x) \quad \text{(by (4.16))},
\]

that is, \( H_n(x) + G_n(x) \leq Q_{i-1}(x) \). Therefore for m-a.e. \( x \in F \),

\[
- \log m_x^{\xi_i-1} (\Gamma_i (x, \rho_n(i, x))) = - \left( \sum_{j=0}^{n-1} H_{n-j}(\sigma_F^j x) \right) - \log m_{\sigma_F^{n-1}}^{\xi_i-1} (\Gamma_i (\sigma_F^n x, 1))
\]

\[
\geq - \sum_{j=0}^{n-1} H_{n-j}(\sigma_F^j x)
\]

\[
\geq \sum_{j=0}^{n-1} (G_{n-j}(\sigma_F^j x) - Q_{i-1}(\sigma_F^j x)) ,
\]

and thus

\[
- \log m_x^{\xi_i-1} (\Gamma_i (x, \rho_n(i, x))) \geq \frac{1}{n} \sum_{j=0}^{n-1} (G_{n-j}(\sigma_F^j x) - Q_{i-1}(\sigma_F^j x)) .
\]

Notice that by Proposition 5.5, when \( n \to +\infty \),

\[
G_n \to Q_i := - \sum_{k=1}^{\infty} \chi_{F_k} \sum_{j=0}^{kN-1} I_m(\mathcal{P}|\tilde{x}_i) \circ \sigma^j
\]

pointwise and in \( L^1 \). By Lemma 2.3, for m-a.e. \( x \in F \),

\[
\liminf_{n \to \infty} \frac{-\log m_x^{\xi_i-1} (\Gamma_i (x, \rho_n(i, x)))}{n} \geq \mathbf{E}_{m_F}((Q_i - Q_{i-1})|\mathcal{I}_F)(x),
\]

where \( \mathcal{I}_F := \{ B \in \mathcal{B}_F : \sigma^{-1}_F(B) = B \} \). In the meantime, by the Birkhoff ergodic theorem,

\[
\lim_{n \to \infty} \frac{-1}{n} \log(\rho_n(i, x)) = \mathbf{E}_{m_F}(N(-\lambda_i + \epsilon)r_F|\mathcal{I}_F)(x)
\]

\[
= N(-\lambda_i(x) + \epsilon)\mathbf{E}_{m_F}(r_F|\mathcal{I}_F)(x) \quad m_F\text{-a.e.},
\]
where we use the fact that \( \lambda_i \) is \( \sigma \)-invariant and thus \( \sigma_F \)-invariant. Hence for \( m \)-a.e. \( x \in F \),

\[
\liminf_{r \to 0} \frac{\log m^{\xi_{i-1}}_x(\Gamma_i(x,r))}{\log r} = \liminf_{n \to \infty} \frac{\log m^{\xi_{i-1}}_x(\Gamma_i(x,\rho_n(i,x)))}{\log(\rho_n(i,x))} \geq \frac{E_m(\mathcal{I}_F(x))}{N(-\lambda_i(x) + \epsilon)} \]

(by Lemma 2.11)

\[
= \frac{h_{i-1}(x) - h_i(x)}{-\lambda_i(x) + \epsilon}.
\]

That is, (5.6) holds. This completes the proof of Proposition 5.1. \( \square \)

6. Local dimensions of invariant measures for affine IFSs

In this section, we prove Theorems 1.2-1.4 and 1.6-1.7.

Let \( M : \Sigma \to \mathbb{R}^{d \times d} \) be the matrix-valued function defined by

\[
M(x) = M_{x-1}, \quad x = (x_j)_{j=-\infty}^\infty.
\]

Let \( m \in M_\sigma(\Sigma) \). Let

\[
\mathbb{R}^d = \bigoplus_{i=1}^s E^i_x \quad (x \in \Sigma')
\]

be the Oseledets splittings of \( \mathbb{R}^d \) associated with \((\Sigma, \sigma^{-1}, m)\) and \( M \) (see Section 4), and \( 0 > \lambda_1(x) > \cdots > \lambda_s(x) \geq -\infty \) the corresponding Lyapunov exponents. Below we prove parts (i) and (ii) of Theorem 1.2 separately.

**Proof of Theorem 1.2(i).** In the beginning we assume that the condition (4.7) holds, that is, for all \( x \in \Sigma' \),

\[
s(x) = s, \quad \text{and} \quad \dim E^i_x = k_i \quad \text{for} \quad i = 1, \ldots, s.
\]

(Just keep in mind that we don’t assume that \( m \) is ergodic at this moment.)

Write \( V^i_x = \bigoplus_{j=i+1}^s E^j_x \) for \( i = 0, \ldots, s-1 \), and \( V^s_x = \{0\} \). Clearly

\[
\{0\} = V^s_x \subset V^{s-1}_x \subset \cdots \subset V^0_x = \mathbb{R}^d.
\]

Let \( \xi_0, \xi_1, \ldots, \xi_s \) be the measurable partitions of \( \Sigma' \) constructed as in Section 4. Furthermore, we set

\[
(6.1) \quad \xi_{-1} = \{\Sigma', \emptyset\} \quad \text{and} \quad \lambda_0(x) = \lambda_1(x) \quad \text{for} \quad x \in \Sigma'.
\]

Clearly \( \xi_{-1}(x) = \Sigma' \) for any \( x \in \Sigma' \). By Lemma 4.4(2), we have

\[
(6.2) \quad Q_{n,\epsilon} \cap \xi_i(x) \cap \mathcal{P}^n_0(x) \subset B^n(x, e^{n(\lambda_i(x) + \epsilon)}), \quad i = -1, 0, \ldots, s-1
\]

when \( n \) is large enough. Here \( B^n(x,r) \) is defined as in (2.3).

For \( i = -1, 0, \ldots, s \), let \( \{m^{\xi_i}_x\} \) be the canonical system of conditional measures associated with \( \xi_i \). By the definition of \( \xi_{-1} \), we see that \( m^{\xi_{-1}}_x = m \) for any \( x \in \Sigma' \).
For \( x \in \Sigma' \) and \( i \in \{0,1,\ldots,s\} \), let \( h_i(x) \) be defined as in (4.15). Write for convention that
\[
h_{-1}(x) = h_0(x).
\]

According to Lemmas 4.6-4.8,
\[
\lim_{n \to \infty} -\frac{\log m_x^\xi(Q_n \cap P_0^\xi(x))}{n+1} = h_i(x) \quad \text{for } m\text{-a.e. } x \in \Sigma', \quad i = -1,0,\ldots,s.
\]

For \( x \in \Sigma' \) and \( r > 0 \), let \( \Gamma_i(x,r) \) be defined as in (5.1), that is,
\[
\Gamma_i(x,r) = \{ y \in \Sigma' : \text{dist}(\pi y + V_i^x, \pi x + V_i^x) \leq r \}, \quad i = 1,\ldots,s.
\]

Write for convention that
\[
\Gamma_0(x,r) = \Sigma'.
\]

It is easy to see that for \( i = 0,1,\ldots,s \),
\[
\Gamma_i(x,r) = \{ y \in \Sigma' : \text{dist}(\pi y + V_i^x, \pi x + V_i^x) \leq r \}, \quad i = 1,\ldots,s.
\]

Moreover, define
\[
\vartheta_i(x) = \liminf_{r \to 0} \frac{\log m_x^\xi(\Gamma_{i+1}(x,r))}{\log r}, \quad i = -1,0,\ldots,s-1.
\]

Clearly \( \vartheta_{-1}(x) = 0 \) for every \( x \in \Sigma' \) since \( \Gamma_0(x,r) = \Sigma' \). Combining this with Proposition 5.1 yields
\[
\vartheta_i(x) \geq \frac{h_{i+1}(x) - h_i(x)}{\lambda_{i+1}(x)} \quad (i = -1,0,\ldots,s-1)
\]
for \( m\text{-a.e. } x \in \Sigma' \).

For \( i = -1,0,\ldots,s \) and \( x \in \Sigma' \), define
\[
\tilde{\delta}_i(x) = \limsup_{r \to 0} \frac{\log m_x^\xi(B_x^\pi(x,r))}{\log r}, \quad \hat{\delta}_i(x) = \liminf_{r \to 0} \frac{\log m_x^\xi(B_x^\pi(x,r))}{\log r}.
\]

We claim that for \( m\text{-a.e. } x \in \Sigma' \),
\begin{align*}
(C1) \quad & \tilde{\delta}_s(x) = \hat{\delta}_s(x) = 0, \\
(C2) \quad & \frac{h_{i+1}(x) - h_i(x)}{\lambda_{i+1}(x)} \geq \tilde{\delta}_i(x) - \hat{\delta}_{i+1}(x) \quad \text{for } i = -1,0,\ldots,s-1, \\
(C3) \quad & \tilde{\delta}_{i+1}(x) + \vartheta_i(x) \leq \hat{\delta}_i(x) \quad \text{for } i = -1,0,\ldots,s-1.
\end{align*}

It is easy to see that (C1)-(C3) together with (6.6) force inductively that for \( m\text{-a.e. } x \in \Sigma' \),
\[
\vartheta_i(x) = \frac{h_{i+1}(x) - h_i(x)}{\lambda_{i+1}(x)} \quad \text{for } i = s-1,\ldots,0,-1, \\
\tilde{\delta}_i(x) = \hat{\delta}_i(x) \quad \text{for } i = s, s-1,\ldots,0,-1
\]
We have
\begin{equation}
\delta_i(x) = \sum_{j=i}^{s-1} \vartheta_j(x) = \sum_{j=i}^{s-1} \frac{h_{j+1}(x) - h_j(x)}{\lambda_{j+1}(x)}
\end{equation}
for \(i = -1, 0, \ldots, s\). In particular,
\begin{equation}
\dim_{ \text{loc} } (m \circ \pi^{-1}, \pi x) = \delta_{-1}(x) = \delta_0(x) = \sum_{i=0}^{s-1} \vartheta_i(x) = \sum_{i=0}^{s-1} \frac{h_{i+1}(x) - h_i(x)}{\lambda_{i+1}(x)}
\end{equation}
for \(m\text{-a.e. } x\), which proves Theorem 1.2(i) under the additional assumption (4.7). In the following we prove (C1)-(C3) respectively.

**Proof of (C1).** Since \(\xi_s(x) = \pi^{-1}(\pi x) \cap \xi_0(x) \subset B^\pi(x, r)\) for any \(x \in \Sigma'\) and \(r > 0\), we have
\[m^\xi_2(B^\pi(x, r)) = m^\xi_2(\xi_s(x)) = 1\]
for all \(x \in \Sigma'\). Thus \(\overline{\delta}_s(x) = \delta_s(x) = 0\) for all \(x \in \Sigma'\).

**Proof of (C2).** We give a proof by contradiction, which is modified from [44, §10.2] and the proof of [28, Theorem 2.11]. Assume that (C2) is not true. Then there exists \(i \in \{-1, 0, \ldots, s-1\}\) such that
\[
\frac{h_{i+1}(x) - h_i(x)}{\lambda_{i+1}(x)} < \overline{\delta}_i(x) - \overline{\delta}_{i+1}(x)
\]
on a set \(U = U_i \subset \Sigma'\) with positive measure. Fix such \(i\). Removing a suitable subset from \(U\) if necessary, we may assume that one of the following holds: (a) \(\lambda_{i+1}(x) \neq -\infty\) for all \(x \in U\); or (b) \(\lambda_{i+1}(x) = -\infty\) and \(\overline{\delta}_i(x) > \overline{\delta}_{i+1}(x)\) for all \(x \in U\). Notice that (b) can not occur unless \(i = s - 1\), since \(\lambda_{i+1}(x) \neq -\infty\) for \(i < s - 1\).

Now we first assume that the scenario (a) occurs. Then there exist \(\alpha > 0\) and real numbers \(h_i, h_{i+1}, \lambda_{i+1}, \overline{\delta}_i, \overline{\delta}_{i+1}\) with \(\lambda_{i+1} < 0\) such that
\begin{equation}
\frac{h_{i+1} - h_i}{\lambda_{i+1}} < \overline{\delta}_i - \overline{\delta}_{i+1} - \alpha
\end{equation}
and for any \(\epsilon > 0\), there exists \(B_\epsilon \subset U\) with \(m(B_\epsilon) > 0\) so that for \(x \in B_\epsilon\),
\[
|h_i(x) - h_i| < \epsilon/2, \quad |h_{i+1}(x) - h_{i+1}| < \epsilon/2, \quad \lambda_{i+1}(x) < \lambda_{i+1} + \epsilon/2
\]
and
\[
\overline{\delta}_i(x) \geq \overline{\delta}_i - \epsilon/2, \quad \overline{\delta}_{i+1}(x) < \overline{\delta}_{i+1} + \epsilon/2.
\]
Fix \(\epsilon \in (0, -\lambda_{i+1}/3)\). There exists \(n_0 : B_\epsilon \to \mathbb{N}\) such that for \(m\text{-a.e. } x \in B_\epsilon\) and \(n > n_0(x)\), we have
\[
\frac{1}{n} \log m^\xi_2(B^\pi(x, e^{n(\lambda_{i+1} + 2\epsilon)}) < \overline{\delta}_{i+1} + \epsilon; \quad \text{(by (4.16))}
\]
\[
\frac{1}{n} \log m^\xi_2(P^0_n(x)) > h_{i+1} - \epsilon
\]
Take $N_0$ such that
\[ \Delta := \{ x \in B_\epsilon : n_0(x) \leq N_0 \} \]
has the positive measure. By Lemma 2.5(1) and Lemma 2.2, there exist $c > 0$ and $\Delta' \subset \Delta$ with $m(\Delta') > 0$ such that for $x \in \Delta'$, there exists $n = n(x) \geq N_0$ such that
\[ \frac{m_x^{\xi_i}(L \cap \Delta)}{m_x^{\xi_i}(L)} > c, \text{ where} \]
\[ L := B^\pi(x, e^{n(\lambda_{i+1} + 2\epsilon)}) \];
\[ \log m_x^{\xi_i}(B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})) \frac{n(\lambda_{i+1} + 2\epsilon)}{\lambda_{i+1} + 2\epsilon} \geq \delta_i - \epsilon; \]
\[ \log(1/c) < \epsilon. \]

Take $x \in \Delta'$ such that (1)–(7) are satisfied with $n = n(x)$. Write $C' = \xi_i(x)$ and $C'' = \xi_{i+1}(x)$. Then by (5) and (1),
\[ m_x^{\xi_i+1}(L \cap \Delta) \geq cm_x^{\xi_i+1}(L) \geq ce^{n(\lambda_{i+1} + 2\epsilon)(\delta_{i+1} + \epsilon)}. \]

But for each $y \in L \cap \Delta$, by (2), $m_y^{\xi_i+1}(P_0^n(y)) < e^{-n(h_{i+1} - \epsilon)}$. It follows that the number of distinct $P_0^n$-atoms intersecting $C \cap L \cap \Delta$ is larger than
\[ m_x^{\xi_i+1}(L \cap \Delta)e^{n(h_{i+1} - \epsilon)}. \]

However each such a $P_0^n$-atom, say $P_0^n(y)$, intersects $C' \cap L \cap \Delta$. This implies that $Q_{n,\epsilon} \cap C' \cap P_0^n(y)$ is contained in $C' \cap B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})$. To see this implication, let $z \in P_0^n(y) \cap \Delta$; since $z \in L \cap \Delta$, we have $d(\pi z, \pi x) \leq e^{n(\lambda_{i+1} + 2\epsilon)}$ and thus
\[ Q_{n,\epsilon} \cap C' \cap P_0^n(y) = Q_{n,\epsilon} \cap \xi_i(z) \cap P_0^n(z) \]
\[ \subset B^\pi(z, e^{n(\lambda_{i+1} + 2\epsilon)}) \quad \text{(by (3))} \]
\[ \subset B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)}), \]
so $Q_{n,\epsilon} \cap C' \cap P_0^n(y) \subset C' \cap B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})$, as desired. In the meantime, by (4),
\[ m_x^{\xi_i}(Q_{n,\epsilon} \cap P_0^n(y)) \geq e^{-n(h_{i+\epsilon})}. \] (To see it, picking $w \in P_0^n(y) \cap C' \cap L \cap \Delta$, we have $\xi_i(x) = \xi_i(w)$ and thus $m_x^{\xi_i}(Q_{n,\epsilon} \cap P_0^n(y)) = m_x^{\xi_i}(Q_{n,\epsilon} \cap P_0^n(w)) \geq e^{-n(h_{i+\epsilon})}$.) Hence
\[ m_x^{\xi_i}(B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})) \geq \#\{P_0^n\text{-atoms intersecting } C' \cap L \cap \Delta\} \cdot e^{-n(h_{i+\epsilon})} \]
\[ \geq m_x^{\xi_{i+1}}(L \cap \Delta)e^{n(h_{i+1} - \epsilon)e^{-n(h_{i+\epsilon})}} \]
\[ \geq ce^{n(\lambda_{i+1} + 2\epsilon)(\delta_{i+1} + \epsilon)}e^{n(h_{i+1} - \epsilon)}e^{-n(h_{i+\epsilon})} \]
\[ \geq 39. \]
Combining the above inequality with (6) yields
\[
(\lambda_{i+1} + 2\epsilon)(\delta_i - \epsilon)
\]
(6.11)
\[
\geq (\lambda_{i+1} + 2\epsilon)(\delta_{i+1} + \epsilon) + \frac{\log c}{n} + h_{i+1} - h_i - 2\epsilon
\]
\[
\geq (\lambda_{i+1} + 2\epsilon)(\delta_{i+1} + \epsilon) + h_{i+1} - h_i - 3\epsilon.
\]
Taking \(\epsilon \to 0\) yields \(h_{i+1} - h_i \leq \lambda_{i+1}(\delta_i - \delta_{i+1})\), which leads to a contradiction with (6.10) (keep in mind that \(\lambda_{i+1} < 0\)).

Next we assume that the scenario (b) occurs, that is, \(\lambda_{i+1}(x) = -\infty\) and \(\delta_i(x) > \delta_{i+1}(x)\) for all \(x \in U\). In this case, \(i = s - 1\), and thus by (C1), \(\delta_{i+1}(x) = \delta_{i+1} := 0\) for all \(x \in U\). Hence there exist real numbers \(h_i, h_{i+1}, \delta_i\) with \(\delta_i > 0\), so that for any \(\epsilon > 0\), there exists \(B_\epsilon \subset U\) with \(m(B_\epsilon) > 0\) such that for \(x \in B_\epsilon\),
\[
|h_i(x) - h_i| < \epsilon/2, \quad |h_{i+1}(x) - h_{i+1}| < \epsilon/2, \quad \delta_i(x) \geq \delta_i - \epsilon/2.
\]
Set \(\lambda_{i+1} = (-1/\epsilon) - 2\epsilon\). Then an argument similar to that for the scenario (a) shows that the previous estimates (1)-(7) hold, and moreover, the inequality (6.11) still holds. Taking \(\epsilon \to 0\) gives \(\delta_i \leq \delta_{i+1} = 0\), leads to a contradiction with \(\delta_i > 0\). \(\square\)

**Proof of (C3).** Here we give a proof by contradiction, following the lines of the proof of [28, Theorem 2.11], in which the arguments were adapted from the original proof of [44, Lemma 11.3.1]. Assume that (C3) is not true. Then there exists \(i \in \{-1,0,\ldots,s-1\}\) such that \(\delta_{i+1}(x) + \vartheta_i(x) > \delta_i(x)\) on a subset of \(\Sigma'\) with positive measure. Hence there exist \(\beta > 0\) and real numbers \(\delta_i, \delta_{i+1}, \vartheta_i\) such that
\[
\delta_{i+1} + \vartheta_i > \delta_i + \beta,
\]
and for any \(\epsilon > 0\), there exists \(A_\epsilon \subset \Sigma'\) with \(m(A_\epsilon) > 0\) so that for \(x \in A_\epsilon\),
\[
|\delta_i(x) - \delta_i| < \epsilon/2, \quad |\delta_{i+1}(x) - \delta_{i+1}| < \epsilon/2, \quad |\vartheta_i(x) - \vartheta_i| < \epsilon/2.
\]
(6.13)
Let \(0 < \epsilon < \beta/4\). Find \(N_1\) and a set \(A'_\epsilon \subset A_\epsilon\) with \(m(A'_\epsilon) > 0\) such that
\[
m^{\xi_{i+1}}_{\epsilon}(B^\pi(x,2e^{-n})) \leq e^{-n(\delta_{i+1} - \epsilon)} \quad \text{for} \quad x \in A'_\epsilon \quad \text{and} \quad n > N_1.
\]
(6.14)
By Lemma 2.5(1) and Lemma 2.2, we can find \(c > 0\) and \(A''_\epsilon \subset A'_\epsilon\) with \(m(A''_\epsilon) > 0\) and \(N_2 > N_1\) such that for all \(x \in A''_\epsilon\) and \(n \geq N_2\),
\[
\frac{m^{\xi_i}_{\epsilon}(A'_\epsilon \cap B^\pi(x,e^{-n}))}{m^{\xi_i}_{\epsilon}(B^\pi(x,e^{-n}))} > c.
\]
For \(x \in A''_\epsilon\) and \(n \geq N_2\), we have
\[
m^{\xi_i}_{\epsilon}(B^\pi(x,e^{-n})) \leq c^{-1}m^{\xi_i}_{\epsilon}(A'_\epsilon \cap B^\pi(x,e^{-n}))
\]
\[
= c^{-1} \int m^{\xi_{i+1}}_{y}(A'_\epsilon \cap B^\pi(x,e^{-n})) \, dm^{\xi_i}_{\epsilon}(y)
\]
\[
= c^{-1} \int_{\Gamma_{i+1}(x,e^{-n})}^{40} m^{\xi_{i+1}}_{y}(A'_\epsilon \cap B^\pi(x,e^{-n})) \, dm^{\xi_i}_{\epsilon}(y),
\]
(6.15)
where in the last equality, we use the fact that $y \in \Gamma_{i+1}(x, e^{-n})$, if $y \in \xi_i(x)$ and $\xi_{i+1}(y) \cap A'_\epsilon \cap B^\pi(x, e^{-n}) \neq \emptyset$. To see this fact, let $y \in \xi_i(x)$ such that $\xi_{i+1}(y) \cap A'_\epsilon \cap B^\pi(x, e^{-n}) \neq \emptyset$. Take $w \in \xi_{i+1}(y) \cap A'_\epsilon \cap B^\pi(x, e^{-n})$. Then $\pi w - \pi y \in V_y^{i+1}$, $\|\pi w - \pi x\| \leq e^{-n}$ and $w^- = y^- = x^-$ which implies $V_w^{i+1} = V_y^{i+1} = V_x^{i+1}$. Hence
\[\text{dist}(\pi y + V_x^{i+1}, \pi x + V_x^{i+1}) = \text{dist}(\pi w + V_x^{i+1}, \pi x + V_x^{i+1}) \leq \|\pi w - \pi x\| \leq e^{-n},\]
and thus $y \in \Gamma_{i+1}(x, e^{-n})$. This completes the proof of the fact. In the above argument, since $\|\pi w - \pi x\| \leq e^{-n}$, we have $A'_\epsilon \cap B^\pi(x, e^{-n}) \subset B^\pi(w, 2e^{-n})$ and thus
\[
m^\xi_{i+1}(A'_\epsilon \cap B^\pi(x, e^{-n})) = m^\xi_{i+1}(A'_\epsilon \cap B^\pi(x, e^{-n})) \leq m^\xi_{i+1}(B^\pi(w, 2e^{-n})) \leq e^{-n(\delta_{i+1} - \epsilon)} \quad (\text{by } (6.14)).
\]
Combining the above inequality with (6.15) yields
\[
m^\xi_{i}(B^\pi(x, e^{-n})) \leq e^{-n}e^{-n(\delta_{i+1} - \epsilon)}m^\xi_{i}(\Gamma_{i+1}(x, e^{-n})) \quad (x \in A'_\epsilon, \ n \geq N_2).
\]
Letting $n \to \infty$, we obtain $\tilde{\delta}_{i}(x) \geq \tilde{\delta}_{i+1} - \epsilon + \vartheta_{i}(x)$ for $x \in A'_\epsilon$. Combining this with (6.13) yields
\[
\tilde{\delta}_{i} \geq \tilde{\delta}_{i+1} + \vartheta_{i} - 4\epsilon \geq \tilde{\delta}_{i+1} + \vartheta_{i} - \beta,
\]
which contradicts (7.3). \qed

So far we have proved Theorem 1.2(i) under the additional assumption (4.7). Now we consider the general case that the integer functions $s(x)$ and $\dim V_x^i, 1 \leq i \leq s(x)$, may not be constant over $\Sigma'$. In such case, by Theorem 2.12 there exists a finite Borel partition
\[
\Sigma' = \bigsqcup_{j=1}^k \Sigma_j
\]
of $\Sigma'$ so that for each $j$, $\Sigma_j$ is $\sigma$-invariant, and $s(x)$ and $\dim V_x^i$ are constant restricted on $\Sigma_j$. Ignore those indices $j$ with $m(\Sigma_j) = 0$. We define probability measures $m_j$ by
\[
m_j = \frac{m|_{\Sigma_j}}{m(\Sigma_j)}.
\]
Then $m_j \in \mathcal{M}_\sigma(\Sigma_j)$. Since now (4.7) holds for $m_j$ (in which $\Sigma'$ is replaced by $\Sigma_j$), we see that (6.9) holds when replacing $m$ by $m_j$. In particular, the local dimension $\dim_{\text{loc}}(m_j \circ \pi^{-1}, \pi x)$ exists for $m_j$-a.e. $x \in \Sigma_j$. Equivalently,
\[
\lim_{r \to 0} \frac{\log m(\Sigma_j \cap B^\pi(x, r))}{\log r} \quad \text{exists for } m\text{-a.e. } x \in \Sigma_j.
\]
By Lemma 2.5(1) and Lemma 2.2, for $m\text{-a.e. } x \in \Sigma_j$, the following
\[
\lim_{r \to 0} \frac{m(\Sigma_j \cap B^\pi(x, r))}{m(B^\pi(x, r))}
\]
exists and takes positive value. This together with (6.16) yields that the local dimension $\dim_{\text{loc}}(m \circ \pi^{-1}, \pi x)$ exists for $m\text{-a.e. } x \in \Sigma_j$. Since $j$ is arbitrarily taken,
**Proof of Theorem 1.2(i).** To see (1.7), let \( i \in \{0, \ldots, s - 1\} \). By (6.8), for \( m\text{-a.e. } x \in \Sigma' \),

\[
\dim_{\text{loc}}(m_x^i \circ \pi^{-1}, \pi x) = \delta_i = \sum_{k=i}^{s-1} \frac{h_{k+1} - h_k}{\lambda_k+1}.
\]

Equivalently, for \( m\text{-a.e. } x \in \Sigma' \) and \( m_x^i \)-a.e. \( y \in \xi_i(x) \),

\[
\dim_{\text{loc}}(m_x^i \circ \pi^{-1}, \pi y) = \delta_i = \sum_{k=i}^{s-1} \frac{h_{k+1} - h_k}{\lambda_k+1}.
\]

Hence for \( m\text{-a.e. } x \in \Sigma' \), \( m_x^i \circ \pi^{-1} \) is exact dimensional with dimension given by (1.7).

Next we prove (1.8) and (1.9). By (6.7), for \( m\text{-a.e. } x \in \Sigma' \),

\[
\vartheta_i(x) = \vartheta_i := \frac{h_{i+1} - h_i}{\lambda_{i+1}} \quad \text{for } i = -1, 0, \ldots, s - 1.
\]

Let \( \Gamma_i(x, r) (x \in \Sigma') \), \( 0 \leq i \leq s \), be defined as in (6.4).

Fix \( j \in \{1, \ldots, s\} \). For \( i = -1, 0, \ldots, j \) and \( x \in \Sigma' \), define

\[
\overline{\gamma}_{i,j}(x) = \limsup_{r \to 0} \frac{\log m_x^i(\Gamma_j(x, r))}{\log r}, \quad \underline{\gamma}_{i,j}(x) = \liminf_{r \to 0} \frac{\log m_x^i(\Gamma_j(x, r))}{\log r}.
\]

We claim that

\[
(6.17) \quad \xi_i(x) \cap \Gamma_j(x, r) = \xi_i(x) \cap g^{-1}(B(gx, r)),
\]

where \( g : \xi_i(x) \to (V_j^* )^\perp \) is defined by \( y \mapsto P_{(V_j^* )^\perp}(\pi y) \). To see this, let \( y \in \xi_i(x) \cap \Gamma_j(x, r) \). Then \( \text{dist}(\pi y + V_j^*, \pi x + V_j^*) \leq r \), equivalently, \( \|gy - gx\| \leq r \); hence \( y \in g^{-1}(B(gx, r)) \). This proves the direction \( \xi_i(x) \cap \Gamma_j(x, r) \subseteq \xi_i(x) \cap g^{-1}(B(gx, r)) \). The other direction can be proved similarly. This completes the proof of (6.18).

Now due to (6.18), we have \( m_x^i(\Gamma_j(x, r)) = m_x^i(g^{-1}(B(gx, r))) \), and so

\[
(6.19) \quad \overline{\gamma}_{i,j}(x) = \dim_{\text{loc}}(m_x^i \circ \pi^{-1} \circ (P_{(V_j^* )^\perp})^{-1}, P_{(V_j^* )^\perp}(\pi x)),
\]

\[
\underline{\gamma}_{i,j}(x) = \dim_{\text{loc}}(m_x^i \circ \pi^{-1} \circ (P_{(V_j^* )^\perp})^{-1}, P_{(V_j^* )^\perp}(\pi x)).
\]

We claim that for \( m\text{-a.e. } x \in \Sigma' \), the following properties hold:

(D1) \( \overline{\gamma}_{i,j}(x) = \underline{\gamma}_{i,j}(x) = 0 \).

(D2) \( h_i - h_{i+1} \geq -\lambda_{i+1}(\overline{\gamma}_{i,j}(x) - \overline{\gamma}_{i+1,j}(x)) \) for \( i = -1, 0, \ldots, j - 1 \).
(D3) \(\gamma_{i,j}(x) + \vartheta_i \leq \gamma_{i,j}(x)\) for \(i = -1, 0, \ldots, j - 1\).

Clearly (D1)-(D3) together with (6.17) force that for m-a.e. \(x \in \Sigma'\),

\[
\gamma_{i,j}(x) = \mathcal{P}_{i,j}(x) \quad \text{for } i = j, j - 1, \ldots, 0, -1,
\]

we write the common value as \(\gamma_i(x)\), and furthermore

\[
\gamma_{-1,j}(x) = \sum_{k=0}^{j-1} \vartheta_k = \sum_{k=0}^{j-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \quad \text{and}
\]

\[
\gamma_{i,j}(x) = \sum_{k=0}^{j-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \quad \text{for } i \in \{0, 1, \ldots, j - 1\}.
\]

Now (1.9) just follows from (6.20) and the fact (6.19). To see (1.8), let \(i \in \{0, \ldots, j - 1\}\). By (6.21) and (6.19), we have for m-a.e. \(x \in \Sigma'\) and \(m_x^\xi\)-a.e. \(y \in \xi_i(x)\),

\[
\dim_{\text{loc}} \left( m_x^\xi \circ \pi^{-1} \circ (P_{(V_j)\perp})^{-1}, P_{(V_j)\perp}(\pi y) \right) = \gamma_{i,j}(x) = \sum_{k=i}^{j-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}},
\]

where we use the fact that \(V^i = V^i_x\) for \(y \in \xi_i(x)\), due to \(y \in \xi_0(x)\) (see Lemma 4.1). As a consequence, for m-a.e. \(x \in \Sigma'\), \(m_x^\xi \circ \pi^{-1} \circ (P_{(V_j)\perp})^{-1}\) is exact dimensional and (1.8) holds. To complete the proof of Theorem 1.4, in the following we prove (D1)-(D3) respectively.

By the definition of \(\xi_j\), for \(x \in \Sigma'\) and \(y \in \xi_j(x)\), we have \(\pi y - \pi x \in V_j^x\) and thus \(\pi y + V_j^x = \pi x + V_j^x\). It follows that \(y \in \Gamma_j(x, r)\). Hence \(\xi_j(x) \subset \Gamma_j(x, r)\) and thus \(m^\xi_j(\Gamma_j(x, r)) = 1\) for \(x \in \Sigma'\) and any \(r > 0\). Hence \(\mathcal{P}_{j,j}(x) = \gamma_{j,j}(x) = 0\) for all \(x \in \Sigma'\). This proves (D1).

The proofs of (D2) and (D3) are almost identical to that of (C2) and (C3), respectively. Indeed we only need to modify the proofs of (C2) and (C3) slightly. More precisely, among other minor adjustments, we may simply replace the terms \(\delta_i, \delta_{i+1}, B^\pi(x, e^{n(\lambda_{i+1} + 2\epsilon)})\), \(B^\pi(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})\), \(B^\pi(x, e^{-n})\) therein by \(\gamma_{i,j}, \gamma_{i+1,j}, \Gamma_j(x, e^{n(\lambda_{i+1} + 2\epsilon)}), \Gamma_j(x, 2e^{n(\lambda_{i+1} + 2\epsilon)})\), and \(\Gamma_j(x, e^{-n})\) respectively. This completes the proof of Theorem 1.4. \(\square\)

As a corollary of Theorem 1.4, we have

**Corollary 6.1.** Under the assumptions of Theorem 1.3, for \(i \in \{0, \ldots, s - 1\}\) and m-a.e. \(x \in \Sigma'\),

\[
\vartheta_i(x) = \lim_{r \to 0} \frac{\log m^\xi_x(\Gamma_{i+1}(x, r))}{\log r} = \frac{h_{i+1} - h_i}{\lambda_{i+1}} \leq k_{i+1}.
\]

**Proof.** Fix \(i \in \{0, \ldots, s - 1\}\). As is proved in Theorem 1.4, for m-a.e. \(x \in \Sigma'\),

\[
\lim_{r \to 0} \frac{\log m^\xi_x(\Gamma_{i+1}(x, r))}{\log r} = \gamma_{i+1}(x) = \frac{h_{i+1} - h_i}{\lambda_{i+1}}.
\]
To see (6.22) it remains to prove that \( \frac{h_{i+1} - h_i}{\lambda_{i+1}} \leq k_{i+1} \). By Theorem 1.4, for \( m \)-a.e. \( x \in \Sigma' \), the measure \( \eta_x := m^x \circ \pi^{-1} \circ (P_{V_{x}^i})^{-1} \) is exact dimensional with dimension \( \frac{h_{i+1} - h_i}{\lambda_{i+1}} \). However, \( \eta_x \) is supported on the affine subspace \( \pi x + (V_x^i \cap V_{x}^{i+1}) \) of dimension \( k_{i+1} \), where \( V_x^i \cap V_{x}^{i+1} \) stands for the orthogonal complement of \( V_x^i \) in \( V_x^i \). Hence \( \dim_H \eta_x \leq k_{i+1} \), and so, \( \frac{h_{i+1} - h_i}{\lambda_{i+1}} \leq k_{i+1} \). \( \square \)

**Lemma 6.2.**  
(i) Let \( m \in \mathcal{M}_\sigma(\Sigma) \) be quasi-Bernoulli. Then for \( m \)-a.e. \( x \in \Sigma \), \( m^x \circ \pi^{-1} \) is strongly equivalent to \( m \circ \pi^{-1} \).

(ii) Let \( m \in \mathcal{M}_\sigma(\Sigma) \) be sub-multiplicative. Then for \( m \)-a.e. \( x \in \Sigma \), \( m^x \circ \pi^{-1} \) is absolutely continuous with respect to \( m \circ \pi^{-1} \).

**Proof.** We first prove (i). Since \( m \) is quasi-Bernoulli, by definition there exists a positive constant \( C \) such that
\[
C^{-1}m([I]_0)m([J]_0) \leq m([I]_0)m([J]_0) \leq Cm([I]_0)m([J]_0)
\]
for all finite words \( I, J \) over \( \Lambda \). Below we show that for \( m \)-a.e. \( x \in \Sigma \),
\[
C^{-1}m([I]_0) \leq m^\xi([I]_0) \leq Cm([I]_0)
\]
for all finite words \( I \) over \( \Lambda \). This is enough to conclude the strong equivalence between \( m^\xi \circ \pi^{-1} \) and \( m \circ \pi^{-1} \), since \( \pi x \) only depends on \( x^+ := (x_n)_{n=0}^\infty \).

To see (6.23), note that the measurable partition \( \xi_0 \) is induced by the mapping \( \tau : \Sigma \to \Sigma^- \), \( x \mapsto x^- = (x_n)_{n=0}^\infty \). That is, \( \xi_0(x) = \{ y \in \Sigma : \tau y = \tau x \} \) for every \( x \).

Applying Lemma 2.5(1) to \( \tau : \Sigma \to \Sigma^- \) yields that for \( m \)-a.e. \( x \),
\[
m^\xi([I]_0) = E_m(\chi_{[I]_0} \tau^{-1}(B(\Sigma^-)))(x) = \lim_{n \to \infty} \frac{m([x_n \ldots x_{-1}1]_0)}{m([x_n \ldots x_{-1}]_0)}
\]
for all finite words \( I \) over \( \Lambda \). (6.23) is then obtained from the quasi-Bernoulli property of \( m \).

Next we prove (ii). Here \( m \) is assumed to be sub-multiplicative and we only have the one-sided inequality \( m([I]_0) \leq Cm([I]_0)m([J]_0) \). However this is enough to derive from (6.24) that for \( m \)-a.e. \( x \),
\[
m^\xi([I]_0) \leq Cm([I]_0)
\]
for all finite words \( I \) over \( \Lambda \). As a consequence, \( m^\xi \circ \pi^{-1} \) is absolutely continuous with respect to \( m \circ \pi^{-1} \), with a uniformly bounded Radon-Nikodym derivative. \( \square \)

**Proof of Theorem 1.6.** We first prove (i). Fix \( i \in \{1, \ldots, s-1\} \). By Theorem 1.4, for \( m \)-a.e. \( x \in \Sigma' \), \( m^x \circ \pi^{-1} \) and \( m^\xi \circ \pi^{-1} \circ (P_{V_x^i})^{-1} \) are exact dimensional with
\[
\dim_H(m^x \circ \pi^{-1}) = \sum_{k=i}^{s-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}}
\]
and
\[
\dim_H(m^\xi \circ \pi^{-1} \circ (P_{V_x^i})^{-1}) = \sum_{k=0}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}},
\]
hence by Theorem 1.3,
\[
\dim_H(m^x \circ \pi^{-1}) + \dim_H(m^\xi \circ \pi^{-1} \circ (P_{V_x^i})^{-1}) = \dim_H(m^\xi \circ \pi^{-1}).
\]
Next let \( x \in \Sigma' \) and write \( W = V_x^i \), \( \nu = m_x^{\xi_0} \), \( \eta = \nu \circ \pi^{-1} \). Notice that \( \nu \) is supported on \( \xi_0(x) \). Consider the measurable partition \( \zeta \) of \( \mathbb{R}^d \) given by

\[
\zeta := \{ W + a : a \in W^\perp \}.
\]

Set \( \pi^{-1}\zeta := \{ \xi_0(x) \cap \pi^{-1}(W + a) : a \in W^\perp \} \). Then \( \pi^{-1}\zeta \) is a measurable partition of \( \xi_0(x) \). Let \( \{ \nu_{y}^{\pi^{-1}\zeta} \}_{y \in \xi_0(x)} \) be the system of conditional measures of \( \nu \) associated with \( \pi^{-1}\zeta \), and \( \{ \eta_{\zeta}^{\pi} \}_{\zeta \in \mathbb{R}^d} \) the system of conditional measures of \( \eta \) associated with \( \zeta \). Write \( \eta_{W,z} := \eta_{\zeta}^{\pi} \). By the uniqueness of conditional measures, we have for \( \nu \)-a.e. \( y \),

\[
\nu_{y}^{\pi^{-1}\zeta} \circ \pi^{-1} = \eta_{W,y}.
\]

Notice also that for \( y \in \xi_0(x) \), the atom \( (\pi^{-1}\zeta)(y) \) is nothing but \( \xi_i(y) \). Hence we have \( \nu_{y}^{\pi^{-1}\zeta} = m_x^{\xi_i} \) for \( m \)-a.e. \( x \) and \( m_x^{\xi_0} \)-a.e. \( y \). This combining with (6.26) gives

\[
m_x^{\xi_i} \circ \pi^{-1} = (m_x^{\xi_0} \circ \pi^{-1})_{V_x^i,\pi_x}
\]

for \( m \)-a.e. \( x \). Plugging the above equality into (6.25), we see that \( m_x^{\xi_0} \circ \pi^{-1} \) satisfies dimension conservation along \( V_x^i \). This proves (i).

Now we turn to the proof of (ii). Suppose that \( m \) is quasi-Bernoulli. By Lemma 6.2(i), for \( m \)-a.e. \( x \in \Sigma' \), \( m_x^{\xi_0} \circ \pi^{-1} \) is strongly equivalent to \( \mu = m \circ \pi^{-1} \); as a consequence, \( m_x^{\xi_0} \circ \pi^{-1} \circ (P_{(V_x^i)^\perp})^{-1} \) is strongly equivalent to \( \mu \circ (P_{(V_x^i)^\perp})^{-1} \). It follows that for \( m \)-a.e. \( x \in \Sigma' \), \( \mu \circ (P_{(V_x^i)^\perp})^{-1} \) is exact dimensional with dimension \( \sum_{k=0}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \). Equivalently, for \( m \circ (\Pi_i)^{-1} \)-a.e. \( W \), \( \mu \circ (P_{W^\perp})^{-1} \) is exact dimensional with dimension \( \sum_{k=0}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \).

Again since \( m_x^{\xi_0} \circ \pi^{-1} \) is strongly equivalent to \( \mu \) for \( m \)-a.e. \( x \), applying Lemma 2.8 to the orthogonal projection \( P_{(V_x^i)^\perp} : \mathbb{R}^d \to (V_x^i)^\perp \), we see that \( m \)-a.e. \( x \), \( \mu_{V_x^i,\pi_x} \) is equivalent to \( (m_x^{\xi_0} \circ \pi^{-1})_{V_x^i,\pi_x} = m_x^{\xi_i} \circ \pi^{-1} \), and so \( \mu_{V_x^i,\pi_x} \) is exact dimensional with dimension \( \sum_{k=s-1}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \). Equivalently, for \( m \circ (\Pi_i)^{-1} \)-a.e. \( W \) and \( m \)-a.e. \( z \), \( \mu_{W,z} \) is exact dimensional with dimension \( \sum_{k=0}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \). Recall that we have proved that for \( m \circ (\Pi_i)^{-1} \)-a.e. \( W \), \( \mu \circ (P_{W^\perp})^{-1} \) is exact dimensional with dimension \( \sum_{k=0}^{i-1} \frac{h_{k+1} - h_k}{\lambda_{k+1}} \).

This is enough to conclude (ii).

Finally, we prove (iii). Suppose that \( m \) is sub-multiplicative. By Lemma 6.2(ii), for \( m \)-a.e. \( x \in \Sigma' \), \( m_x^{\xi_0} \circ \pi^{-1} \) is absolutely continuous with respect to \( \mu \). Hence there exists \( H \subset \Sigma' \) with full \( m \)-measure such that for any \( x \in H \), there exists a Borel set \( F_x \subset \mathbb{R}^d \) with positive \( \mu \)-measure such that \( (m_x^{\xi_0} \circ \pi^{-1})_{F_x} \) is strongly equivalent to \( \mu_{F_x} \), where \( \nu_A \) stands for the probability measure defined by \( \nu_A(\cdot) = \nu(A \cap \cdot) / \nu(A) \).

As is proved in part (ii), when \( m \) is quasi-Bernoulli, we can take \( F_x = \Sigma \).

Now fix \( x \in H \) and \( i \in \{1, \ldots, s-1\} \). Set \( W = V_x^i \) and write for convenience

\[
\eta := m_x^{\xi_0} \circ \pi^{-1}, \quad \eta' := (m_x^{\xi_0} \circ \pi^{-1})_{F_x}, \quad \mu' := \mu_{F_x}.
\]
Applying Lemma 2.9 to the projection $P_{W^\perp}: \mathbb{R}^d \to \mathbb{R}^d$ and using the Borel density lemma, we see that for $\mu$-a.e. $z \in F_x$ (equivalently for $\eta$-a.e. $z \in F_x$),
\[
\dim_{\text{loc}}((\eta')_{W,z}, z) = \dim_{\text{loc}}(\eta_{W,z}, z),
\]
\[
\dim_{\text{loc}}((\mu')_{W,z}, z) = \dim_{\text{loc}}(\mu_{W,z}, z),
\]
(6.28)
\[
\dim_{\text{loc}}(\eta' \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)) = \dim_{\text{loc}}(\eta \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)),
\]
\[
\dim_{\text{loc}}(\mu' \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)) = \dim_{\text{loc}}(\mu \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)).
\]

Since $\eta'$ and $\mu'$ are strongly equivalent, by Lemma 2.8, for $\mu$-a.e. $z \in F_x$,
\[
\dim_{\text{loc}}((\eta')_{W,z}, z) = \dim_{\text{loc}}((\mu')_{W,z}, z),
\]
\[
\dim_{\text{loc}}(\eta' \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)) = \dim_{\text{loc}}(\mu' \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)).
\]

Combining the above equalities with (6.28) yields that for $\mu$-a.e. $z \in F_x$,
\[
\dim_{\text{loc}}(\mu_{W,z}, z) = \dim_{\text{loc}}(\eta_{W,z}, z),
\]
\[
\dim_{\text{loc}}(\mu \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)) = \dim_{\text{loc}}(\eta \circ (P_{W^\perp})^{-1}, P_{W^\perp}(z)).
\]

Now (iii) follows from (i). This completes the proof of the theorem. \qed

**Proof of Theorem 1.7.** Here we only give a sketched proof. It is based on [28, Theorem 2.11] and its proof.

Since the linear parts $M_j$ of $\mathcal{S}$ commute, $\mathbb{R}^d$ can be decomposed into the direct sum $T_1 + \cdots + T_\ell$ of some subspaces with dimensions $q_1, \ldots, q_\ell$, so that for each pair $(j,p) \in \Lambda \times \{1, \ldots, \ell\}$, $M_j T_p \subset T_p$ and $M_j$ is “weakly conformal” on $T_p$ in the sense that there exists $a_{j,p} \geq 0$ so that $\lim_{n \to \infty} \|M^v_j\|^n = a_{j,p}$ for $v \in T_p \setminus \{0\}$. Hence under a suitable coordinate change, $\mathcal{S}$ can be written as the direct product of some “weakly conformal” affine IFSs $\mathcal{S}_1, \ldots, \mathcal{S}_\ell$ on $\mathbb{R}^{q_1}, \ldots, \mathbb{R}^{q_\ell}$ (cf. [28, Definition 2.10]).

Set $\bar{\lambda}_p = \sum_{j \in \Lambda} m([j]_0) \log a_{j,p}$ for $p = 1, \ldots, \ell$. Permuting $\mathcal{S}_j$’s if necessary, we may assume that
\[
\bar{\lambda}_1 \geq \cdots \geq \bar{\lambda}_\ell.
\]
For $p \in \{1, \ldots, \ell\}$ and let $\tau_p$ be the orthogonal projection from $\mathbb{R}^d$ to $Y_p := \mathbb{R}^{q_1} \times \cdots \times \mathbb{R}^{q_\ell}$, and let $m^{\pi^p}_\sigma$ be the conditional measure of $m$ associated with the measurable partition $\{\pi^{-1} \circ \tau^{-1}_p(y) : y \in Y_p\}$ of $\Sigma$. It is implicitly proved in [28, Theorem 2.11] that there exist $h_m(\sigma) = \bar{h}_0 \geq \bar{h}_1 \geq \cdots \geq \bar{h}_\ell \geq 0$ such that for $m$-a.e. $x \in \Sigma$ and $p \in \{1, \ldots, \ell - 1\}$, the measure $m^{\pi^p}_\sigma$ is exact dimensional with dimension $\sum_{j=p}^{\ell-1} \frac{\bar{h}_{j+1} - \bar{h}_j}{\bar{\lambda}_{j+1}}$, and moreover, $\mu = m \circ \pi^{-1}$ is exact dimensional with dimension $\sum_{j=0}^{p-1} \frac{\bar{h}_{j+1} - \bar{h}_j}{\bar{\lambda}_{j+1}}$. (We remark that this is only proved in [28] in the case when $\mathcal{S}$ is invertible and contracting. But it can be extended to the general case like Theorem 1.6.) Applying this result to the IFS $\mathcal{S}_1 \times \cdots \times \mathcal{S}_p$ gives that $\mu \circ \tau^{-1}_p$ is exact dimensional with dimension $\sum_{j=0}^{p-1} \frac{\bar{h}_{j+1} - \bar{h}_j}{\bar{\lambda}_{j+1}}$.

Set $\mu = m \circ \pi^{-1}$. Let $\{\mu_{y^p_{W,z}}\}$ denote the system of conditional measures of $\mu$ associated with the measurable partition $\{\tau^{-1}_p(y) : y \in Y_p\}$ of $\mathbb{R}^d$. Similar to the
proof of (6.27), we can show that for $m$-a.e. $x \in \Sigma$, $\mu_{Y^\perp p, x} = m^0 \circ \pi^{-1}$. It follows that $\mu$ is dimension conserving with respect to the projection $\tau_p$. Moreover, $\mu_{Y^\perp p, x}$ is exact dimensional for $\mu$-a.e. $x$.

Now let $1 \leq p_1 < \cdots < p_{s'} = \ell$ be those integers so that

$$\overline{\lambda}_1 = \cdots = \overline{\lambda}_{p_1} > \overline{\lambda}_{p_1+1} = \cdots = \overline{\lambda}_{p_2} > \cdots > \overline{\lambda}_{p_{s'-1}+1} = \cdots = \overline{\lambda}_{p_{s'}}.$$ 

It is readily checked that $s = s'$, $\lambda_i = \overline{\lambda}_{p_i}$ and $V^i_x = W^i := Y^i_{p_i}$ for $1 \leq i \leq s$ and $m$-a.e. $x$. In particular, $P_{(W^i)_+} = \tau_{p_i}$ for $i = 1, \ldots , s - 1$. Hence $\mu$ is dimension conserving with respect to the projections $P_{(W^i)_+}$, $i = 1, \ldots , s - 1$.

\[\square\]

**Remark 6.3.** The proof of Theorem 1.7 implies the following result: Let $S = \{S_j(x) = r_j x + a_j\}_{j \in \Lambda}$ be a self-similar IFS on $\mathbb{R}^d$ with $r_j > 0$, average contracting with respect to an ergodic $m \in \mathcal{M}_\sigma(\Sigma)$. Then for any proper subspace $W$ of $\mathbb{R}^d$, $m \circ \pi^{-1}$ is dimension conserving with respect to $P_W$. This generalizes the result in [24, 33]. To see it, let $p = \dim W$ and let $v_1, \ldots , v_p$ be an orthonormal basis of $\mathbb{R}^d$ such that $\text{span}(v_1, \ldots , v_p) = W$. Then one can check that $S$ can be written as the product $S_1 \times \cdots \times S_d$ of some one-dimensional IFSs on $X_1, \ldots , X_d$, where $X_i = \text{span}(v_i)$, and moreover $\overline{\lambda}_1 = \cdots = \overline{\lambda}_d$. Now the desired dimension conservation property follows from the proof of Theorem 1.7.

### 7. Lyapunov Dimension

Throughout this section, let $m$ be an ergodic $\sigma$-invariant measure on $\Sigma$ and $M = (M_j)_{j \in \Lambda}$ be a tuple of $d \times d$ real matrices satisfying

$$\lambda(M, m) := \lim_{n \to \infty} \frac{1}{n} \int \log \|M_{x_0} \cdots M_{x_{n-1}}\| \, dm(x) < 0.$$ 

Let $S = \{S_i(x) = M_j x + a_j\}_{j \in \Lambda}$ be an affine IFS on $\mathbb{R}^d$. Let $\{(\lambda_i, k_i)\}_{1 \leq i \leq s}$ be the Lyapunov spectrum of $M$ with respect to $(\Sigma, \sigma^{-1}, m)$. Set

$$L_0 = 0 \quad \text{and} \quad L_i = -\sum_{\ell=1}^i \lambda_{i\ell} \ell \quad \text{for} \quad i = 1, \ldots , s.$$ 

Clearly $L_0 < L_1 < \cdots < L_s$. Following [40], we give the following.

**Definition 7.1.** The Lyapunov dimension of $m$ with respect to $M$, denoted as $\dim_L(m, M)$, is defined to be

$$\left\{ \begin{array}{ll}
\left( \sum_{\ell=0}^{j-1} k_\ell \right) + \frac{h_m(\sigma) - L_{j-1}}{(-\lambda_j)} & \text{if} \ L_{j-1} \leq h_m(\sigma) < L_j \text{ for some } j \in \{1, \ldots , s\}, \\
\frac{d h_m(\sigma)}{L_s} & \text{if} \ h_m(\sigma) \geq L_s.
\end{array} \right.$$ 

Let $\pi$ be the coding map associated with $S$. Recall that $h_i$, $0 \leq i \leq s$, are the conditional entropies of $m$ defined in (4.15), and $h_0 = h_m(\sigma)$. The following result says that the Lyapunov dimension of $m$ is always an upper bound for the Hausdorff
Remark 7.3. By Proposition 7.2, if 
\[ \Delta := \max_i \left\{ h_i - h_i - L_i \right\} \] 
holds if and only if one of the following holds:

1. \( h_m(\sigma) \geq L_s \) and \( h_i = h_m(\sigma) - L_i \) for all \( i \in \{1, \ldots, s\} \).
2. \( h_m(\sigma) \in [L_{j-1}, L_j) \) for some \( j \in \{1, \ldots, s\} \), and
\[ h_i = \begin{cases} h_m(\sigma) - L_i & \text{if } 1 \leq i \leq j - 1, \\ 0 & \text{if } j \leq i \leq s. \end{cases} \]

Proof. Since \( \lambda(M, m) < 0 \), the IFS \( S \) is average contracting with respect to \( m \). By Theorem 1.3, \( \dim_H m \circ \pi^{-1} = \sum_{i=0}^{s-1} \frac{h_{i+1} - h_i}{\lambda_{i+1}} \). Recall that
\[ 0 > \lambda(M, m) = \lambda_1 > \cdots > \lambda_s \geq -\infty, \]
and
\[ h_m(\sigma) = h_0 \geq h_1 \geq \cdots \geq h_s \geq 0. \]
Moreover by Corollary 6.1, \( h_i - h_{i+1} \leq (-\lambda_{i+1})k_{i+1} \) for each \( i \). Hence \( \dim_H m \circ \pi^{-1} \) is bounded above by
\[ \Delta := \max \left\{ \sum_{i=0}^{s-1} \frac{x_{i+1} - x_i}{\lambda_{i+1}} : h_m(\sigma) = x_0 \geq \cdots \geq x_s \geq 0, \frac{x_{i+1} - x_i}{\lambda_{i+1}} \leq k_{i+1} \right\} \] \( \forall i \).

Now it is readily checked that the following hold: (a) if \( h_m(\sigma) \geq L_s \), then \( \Delta = d \) and the maximum in defining \( \Delta \) is attained uniquely at \( (x_1, \ldots, x_s) \) where \( x_i = h_m(\sigma) - L_i \) for \( 0 \leq i \leq s \); (b) if \( h_m(\sigma) \in [L_{j-1}, L_j) \) for some \( j \in \{1, \ldots, s\} \), then
\[ \Delta = \left( \sum_{\ell=0}^{j-1} k_{\ell} \right) + \frac{h_m(\sigma) - L_j}{-\lambda_j}, \]
and the maximum is attained uniquely at \( (x_1, \ldots, x_s) \) where \( x_i = h_m(\sigma) - L_i \) for \( i \leq j - 1 \) and 0 for \( i \geq j \). As a consequence, the results of the proposition hold. \( \square \)

Remark 7.3. By Proposition 7.2, if \( \dim_H m \circ \pi^{-1} = \min\{d, \dim_{LY}(m, M)\} \), then
\[ \sum_{\ell=1}^{j} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = \min\{k_1 + \cdots + k_j, \dim_H m \circ \pi^{-1}\} \quad \text{for } j = 1, \ldots, s. \]

This result was partially proved in [4, Corollary 2.7].

Proposition 7.4. Suppose that \( S \) is contracting and satisfies the strong separation condition. Then the following statements hold.

(i) \( h_s = 0, h_m(\sigma) < L_s \) and \( \dim_{LY}(m, M) < d \).
(ii) Let \( j \) be the unique element in \( \{1, \ldots, s\} \) so that \( L_{j-1} \leq h_m(\sigma) < L_j \). Then
\( \dim_H m \circ \pi^{-1} = \dim_{LY}(m, M) \) if and only if
\[ \sum_{\ell=1}^{j-1} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = d_{j-1}, \quad \sum_{\ell=j+1}^{s} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = 0, \]
where \( d_0 := 0 \) and \( d_i := k_1 + \cdots + k_i \) for \( 1 \leq i \leq s \).

**Proof.** (i) We first claim that \( h_s = 0 \). Since \( \mathcal{S} \) satisfies the strong separation condition, \( \xi_s(x) = \{x\} \) for each \( x \in \Sigma \). Thus \( \hat{\xi}_s = B(\Sigma) \) and hence \( h_s = H_m(P\xi_s) = 0 \).

Next we prove that \( h_m(\sigma) < L_s \). Clearly this is true if \( L_s = \infty \) (equivalently, if \( \lambda_s = -\infty \)). Below we assume that \( \lambda_s > -\infty \).

Let \( K \) denote the self-affine set generated by \( \mathcal{S} \). For \( \delta > 0 \) let \( K_\delta \) be the closed \( \delta \)-neighborhood of \( K \), i.e. \( K_\delta = \{z : d(z, K) \leq \delta\} \). Since \( \mathcal{S} \) satisfies the strong separation condition, we can pick a small \( \delta \) such that \( S_i(K_\delta) \ (i \in \Lambda) \) are disjoint subsets of the interior of \( K_\delta \) and hence \( \mathcal{L}^d(K_\delta) > \sum_{i \in \Lambda} \mathcal{L}^d(S_i(K_\delta)) \). It follows that \( \rho := \sum_{i \in \Lambda} |\det(M_i)| < 1 \).

Since \( m \) is ergodic \( \sigma \)-invariant, by [30, Lemma 3.2] and the Shannon-McMillan-Breiman theorem, for \( m \)-a.e. \( x \in \Sigma \),

\[
(7.2) \quad \lim_{n \to \infty} \frac{\log |\det(M_{x_0, \ldots, x_{n-1}})|}{n} = -L_s, \quad \lim_{n \to \infty} \frac{\log m([x_0 \ldots x_{n-1}])}{n} = -h_m(\sigma).
\]

For \( \epsilon > 0 \) and \( n \in \mathbb{N} \), let \( \Lambda_{n, \epsilon} \) denote the set of words \( I \) of length \( n \) over the alphabet \( \Lambda \) such that

\[
|\det(M_I)| \geq e^{-nL_s - n\epsilon}, \quad m([I]_0) \leq e^{-nh_m(\sigma) + n\epsilon}.
\]

By (7.2), \( \lim_{n \to \infty} \sum_{I \in \Lambda_{n, \epsilon}} m([I]_0) = 1 \). Notice that

\[
\rho^n = \sum_{I \in \Lambda^n} |\det(M_I)| \geq \sum_{I \in \Lambda_{n, \epsilon}} |\det(M_I)| \geq \sum_{I \in \Lambda_{n, \epsilon}} e^{-nL_s - n\epsilon} \cdot \frac{m([I]_0)}{e^{-nh_m(\sigma) + n\epsilon}} = e^{-n(L_s - h_m(\sigma) - 2\epsilon)} \cdot \left( \sum_{I \in \Lambda_{n, \epsilon}} m([I]_0) \right).
\]

Letting \( n \to \infty \) and \( \epsilon \to 0 \), we obtain the desired inequality \( h_m(\sigma) \leq L_s + \log \rho < L_s \).

Now the inequality \( \dim_{\text{LY}}(m, M) < d \) follows directly from Definition 7.1. This proves (i).

Finally we prove (ii). Since \( h_s = 0 \) and \( 0 \leq h_{\ell-1} - h_\ell \leq (-\lambda_\ell)k_\ell \) for each \( \ell \) by Corollary 6.1, we see that (7.1) holds if and only if \( h_{\ell-1} - h_\ell = (-\lambda_\ell)k_\ell \) for \( 1 \leq \ell \leq j-1 \) and \( h_j = 0 \) for \( j \leq \ell \leq s \). By Proposition 7.2, this is equivalent to that \( \dim_{\text{H}} m \circ \pi^{-1} = \dim_{\text{LY}}(m, M) \).

\( \square \)

**Remark 7.5.** Theorems 1.6 (resp. Theorem 1.7) can be applied to estimate the dimension of slices and projections of certain self-affine sets. To see it, let \( K \) a self-affine sets generated by a contracting affine IFS \( \{S_j = M_j x + a_j\}_{j \in \Lambda} \) on \( \mathbb{R}^d \). Suppose that there exists an ergodic \( m \in \mathcal{M}_{\sigma}(\Sigma) \) so that

\[
(7.3) \quad \dim_{\text{H}} m \circ \pi^{-1} = \dim_{\text{H}} K.
\]
Follow the notation in Theorem 1.6 and assume $s \geq 2$. Since the slicing measures $(m_x^s \circ \pi^{-1})_{V^x_i + y}$ are supported on the slices $K \cap (V^x_i + y)$, by using Theorem 1.6(i) and a general inequality in Theorem 2.10.25 of Federer [27], we obtain that for $i \in \{1, \ldots, s-1\}$ and $m$-a.e. $x$,

$$\dim_H K \cap (V^x_i + y) = \sum_{\ell=i}^{s-1} \frac{h_{\ell+1} - h_\ell}{\lambda_{\ell+1}}$$

for $(m_x^s \circ \pi^{-1}) \circ P^{-1}_{(V^x_i)^{\perp}}$-a.e. $y \in (V^x_i)^{\perp}$

and

(7.4)

$$\dim_H \left\{ y \in P_{(V^x_i)^{\perp}}(K) : \dim_H K \cap (V^x_i + y) = \sum_{\ell=i}^{s-1} \frac{h_{\ell+1} - h_\ell}{\lambda_{\ell+1}} \right\} = \sum_{\ell=0}^{i-1} \frac{h_{\ell+1} - h_\ell}{\lambda_{\ell+1}}.$$

If in addition to the assumption (7.3), we further assume that $\dim_H m \circ \pi^{-1} = \dim_{LY}(m, M)$, then

(7.5) \quad \dim_H P_{(V^x_i)^{\perp}}(K) = \min\{\dim((V^x_i)^{\perp}), \dim_H K\} \quad \text{for } m\text{-a.e. } x.$$

Indeed by Remark 7.3, the sum in the right-hand side of (7.4) is equal to

$$\min\{\dim((V^x_i)^{\perp}), \dim_H m \circ \pi^{-1}\},$$

and hence equal to $\min\{\dim((V^x_i)^{\perp}), \dim_H K\}$. Now (7.5) follows from (7.4).

8. Semi-continuity of entropies and dimensions

In this section, we prove Theorems 1.8-1.10. Set

(8.1) \quad f(x) = \sum_{n=1}^{\infty} \|M_{x_0} \cdots M_{x_{n-1}}\| \quad \text{for } x \in \Sigma.$$

**Lemma 8.1.** Let $\eta$ be a Borel probability measure on $\Sigma$ with $\eta(\{f = \infty\}) = 0$. Then $\eta \circ \pi_n^{-1}$ depends continuously on $a$, in the sense that $\eta \circ \pi_n^{-1}$ converges to $\eta \circ \pi_{a_n}^{-1}$ weakly when $a_n$ converges to $a$.

**Proof.** Since $f(x) < \infty$ for $\eta$-a.e. $x \in \Sigma$, $\pi_{a}(x)$ is well-defined for every $a \in \mathbb{R}^{d|A|}$ and moreover,

(8.2) \quad \|\pi_{a}(x) - \pi_{b}(x)\| \leq f(x)\|a - b\|.$$

For $N \in \mathbb{N}$, set $A_N := \{x : f(x) < N\}$.

Let $(a_n) \subset \mathbb{R}^{d|A|}$ so that $\lim_{n \to \infty} a_n = a$. For convenience, write $\nu_n = \eta \circ \pi_{a_n}^{-1}$ and $\nu = \eta \circ \pi_{a}^{-1}$. To show that $\nu_n$ converges weakly to $\nu$, by the Portmanteau theorem, it suffices to show that $\limsup_{n \to \infty} \nu_n(F) \leq \nu(F)$ for any compact set $F \subset \mathbb{R}^d$.

Now fix a compact set $F \subset \mathbb{R}^d$. Let $\epsilon > 0$. Take a small $r > 0$ so that $\nu(V_r(F)) \leq \nu(F) + \epsilon$, where $V_r(F)$ stands for the $r$-neighborhood of $F$. Take a large $N$ so that $\eta(\Sigma \setminus A_N) < \epsilon$. Pick $n_0$ so that $\|a_n - a\| < r/N$ when $n \geq n_0$. 

50
By (8.2), for \( x \in A_N \) and \( n \geq n_0 \) we have \( \| \pi_{a_n}(x) - \pi_a(x) \| \leq N \| a_n - a \| < r \). Hence \( A_N \cap \pi_{a_n}^{-1}(F) \subset A_N \cap \pi_a^{-1}(V_r(F)) \) for \( n \geq n_0 \). It follows that for \( n \geq n_0 \),
\[
\nu_n(F) = \eta(\pi_{a_n}^{-1}(F)) \leq \eta(\Sigma \setminus A_N) + \eta(A_N \cap \pi_{a_n}^{-1}(F)) \\
\leq \epsilon + \eta(A_N \cap \pi_a^{-1}(V_r(F))) \\
\leq \epsilon + \nu(V_r(F)) \leq \nu(F) + 2\epsilon.
\]
Hence \( \limsup_{n \to \infty} \nu_n(F) \leq \nu(F) + 2\epsilon \). Letting \( \epsilon \to 0 \) gives \( \limsup_{n \to \infty} \nu_n(F) \leq \nu(F) \), as desired.

**Proof of Theorem 1.8.** We first prove part (1) of the theorem. This is done by extending an idea of Rapaport [59, Lemma 8].

It is implicitly proved in Proposition 3.1 that \( m(\{ f = \infty \}) = 0 \), where \( f \) is defined as in (8.1). Let \( i \in \{ 1, \ldots, s \} \) and write \( \xi_{i,a} \) for \( \xi_i \) so as to emphasize its dependence on \( a \). Since

\[
0 = m(\{ f = \infty \}) = \int m_{\xi_{i,a}}^c(\{ f = \infty \}) dm(x),
\]
the set \( \Delta_a := \{ x \in \Sigma' : m_{\xi_{i,a}}^c(\{ f = \infty \}) = 0 \} \) has full \( m \)-measure.

Noticing that \( \xi_0 \) is independent of \( a \), and \( \xi_{i,a} \) is a refinement of \( \xi_0 \) (i.e. any set in \( \xi_{i,a} \) is a subset of an element in \( \xi_0 \)), we have

\[
h_{i,a} = H_m(\mathcal{P}|\xi_{i,a}) = \int -\log m_{\xi_{i,a}}^c(\mathcal{P}(x)) \ dm(x)
= \int \int -\log m_{\xi_{i,a}}^c(\mathcal{P}(y)) \ dm_{\xi_{i,a}}^c(y) \ dm(x)
= \int H_m(\mathcal{P}|\xi_{i,a}) \ dm(x).
\]

Fix \( a_0 \in \mathbb{R}^{d|A|} \). In what follows we show that \( h_{i,a} \) is upper semi-continuous in \( a \) at \( a_0 \). Since \( \Delta_{a_0} \) has full \( m \)-measure, \( h_{i,a} = \int_{\Delta_{a_0}} H_m(\mathcal{P}|\xi_{i,a}) \ dm(x) \). Hence it is sufficient to show that \( a \mapsto \int_{\Delta_{a_0}} H_m(\mathcal{P}|\xi_{i,a}) \ dm(x) \) is upper semi-continuous at \( a_0 \) for every \( x \in \Delta_{a_0} \). For this purpose, fix \( x \in \Delta_{a_0} \) and write \( C = \xi_0(x) \), \( W = V_x^i \) and \( m_C = m_x^{\xi_0} \). Then by the definition of \( \xi_{i,a} \),

\[
H_m(\mathcal{P}|\xi_{i,a}) = H_m(\mathcal{P}|\pi_a^{-1} \circ P_{W}^{-1}(\mathcal{B}(W^\perp))).
\]

Following the proof of [66, Lemma 8.5] or [59, Lemma 8] with minor changes, we can construct a sequence \( (\beta_n) \) of finite Borel partitions of \( W^\perp \) such that (i) \( \sigma(\beta_n) \uparrow \mathcal{B}(W^\perp) \) and (ii) \( m_C \circ \pi_{a_0}^{-1}(P_{W_1}^{-1}(\partial B)) = 0 \) for any \( B \in \bigcup_n \beta_n \). Since \( \sigma(\beta_n) \uparrow \mathcal{B}(W^\perp) \),

\[
H_m(\mathcal{P}|\pi_a^{-1} \circ P_{W}^{-1}(\mathcal{B}(W^\perp))) = \lim_{n \to \infty} H_m(\mathcal{P}|\pi_a^{-1} \circ P_{W}^{-1}(\sigma(\beta_n)))
= \lim_{n \to \infty} \sum_{A \in \mathcal{P}} \sum_{B \in \beta_n} \mu((m_C|_A) \circ \pi_a^{-1}(P_{W}^{-1}(B))),
\]

51
where \( u(z) := -z \log z \). Since \( x \in \Delta_{a_0}, \) \( m_C(\{ f = \infty \}) = 0 \). By Lemma 8.1, the measures \( m_C \circ \pi_a^{-1} \) and \( (m_C|_A) \circ \pi_a^{-1} (A \in \mathcal{P}) \) depend continuously on \( a \); and so do \( m_C \circ \pi_a^{-1} \circ P_{W}^{-1} \) and \( (m_C|_A) \circ \pi_a^{-1} \circ P_{W}^{-1} \). It follows that, as functions of \( a \), \( u \left((m_C|_A) \circ \pi_a^{-1} \circ P_{W}^{-1}(B)) \right) \) and \( u \left((m_C|_A) \circ \pi_a^{-1} \circ P_{W}^{-1}(A \in \mathcal{P}) \right) \) are continuous at \( a_0 \), and so is \( H_{m_C}(\pi_a^{-1} \circ P_{W}^{-1}(\sigma(\beta_n)) \). Hence \( a \mapsto H_{m_C}(\pi_a^{-1} \circ P_{W}^{-1}(B(W))) \) is upper semi-continuous at \( a_0 \), as desired. This proves the upper semi-continuity of \( h_{i,a} \).

Next we prove the lower semi-continuity of the mapping \( a \mapsto \dim_H(m \circ \pi_a^{-1}) \). By Theorem 1.3, we have

\[
(8.3) \quad \dim_H(m \circ \pi_a^{-1}) = \sum_{i=0}^{s} t_i h_{i,a},
\]

where \( t_0 = -\frac{1}{\lambda_1} \) and \( t_i = \frac{1}{\lambda_i} - \frac{1}{\lambda_{i+1}} \) for \( i = 1, \ldots, s \), with convention \( \lambda_{s+1} := -\infty \). Notice that \( t_0 > 0, t_i \leq 0 \) for \( 1 \leq i \leq s \) and moreover, \( h_{0,a} \equiv h_\sigma(m) \). By part (1), \( h_{i,a}, \ldots, h_{s,a} \) are upper semi-continuous in \( a \). Hence by (8.3), \( \dim_H(m \circ \pi_a^{-1}) \) is lower semi-continuous in \( a \).

**Remark 8.2.** Theorem 1.8 can be further extended. For given \( m \) and \( M = (M_j)_{j \in \Lambda} \), let \( S_{r,a} \) denote the IFS \( \{ r_j M_j x + a_j \}_{j \in \Lambda} \) where \( r = (r_j)_{j \in \Lambda} \in (\mathbb{R} \setminus \{0\})^\Lambda \) so that \( S_{r,a} \) is average contracting with respect to \( m \). Notice that the Oseledets subspaces with respect to \( m \) and \( (r_j M_j)_{j \in \Lambda} \) are independent of \( r \). A slight modification of the above proof establishes the upper semi-continuity of \( (r,a) \mapsto h_{i,r,a} \) and the lower semi-continuity of \( (r,a) \mapsto \dim_H(m \circ \pi_a^{-1}) \).

**Proof of Theorem 1.9.** We first prove (i). Let \( m \) be an ergodic \( \sigma \)-invariant measure \( m \) on \( \Sigma \). For \( n \in \mathbb{N} \), set

\[
\Omega_n := \left\{ a \in \mathbb{R}^{d|\Lambda|} : \dim_H(m \circ \pi_a^{-1}) \leq \min(d, \dim_{LY}(m, M)) - \frac{1}{n} \right\}.
\]

Since \( \dim_H(m \circ \pi_a^{-1}) \) is lower semi-continuous in \( a \) by Theorem 1.8, \( \Omega_n \) is closed for each \( n \). Meanwhile, it was proved in [40] that \( \dim_H(m \circ \pi_a^{-1}) = \min(d, \dim_{LY}(m, M)) \) for \( L^d|\Lambda| \)-a.e. \( a \). Hence for each \( n \), \( \Omega_n \) is a closed set of zero Lebesgue measure, so it is nowhere dense. This is enough to conclude (i).

Next we prove (ii). It was shown by Käenmäki [41] that there exists an ergodic \( \sigma \)-invariant measure \( \eta \) on \( \Sigma \) such that \( \dim_{LY}(\eta, M) = \dim_{AFF}(M) \). Fix such \( \eta \). Note that for each \( a \),

\[
\dim_H(\eta \circ \pi_a^{-1}) \leq \dim_H K(M, a) \leq \min(d, \dim_{AFF}(M)).
\]

It implies that

\[
\{ a \in \mathbb{R}^{d|\Lambda|} : \dim_H K(M, a) \neq \min(d, \dim_{AFF}(M)) \}
\]

\[
\subset \left\{ a \in \mathbb{R}^{d|\Lambda|} : \dim_H(\eta \circ \pi_a^{-1}) \neq \min(d, \dim_{LY}(\eta, M)) \right\}.
\]

Now (ii) follows from (i). \( \square \)

To prove Theorem 1.10 we need the following.
Lemma 8.3 ([59, Lemma 22]). Let \( \mu \) be a probability Borel measure on \( \mathbb{R}^d \) and \( 1 \leq k < d \). Then the following statements hold.

(i) If \( \dim_H \mu \leq k \) then for \( 0 < t \leq \dim_H \mu \),
    \[
    \dim_H \{ W \in G(d, k) : \dim_H \mu \circ (P_W)^{-1} < t \} \leq k(d - k - 1) + t.
    \]

(ii) If \( \dim_H \mu \geq k \) then for \( \dim_H \mu - k(d - k) < t \leq k \),
    \[
    \dim_H \{ W \in G(d, k) : \dim_H \mu \circ (P_W)^{-1} < t \} \leq k(d - k) + t - \dim_H \mu.
    \]

Proof of Theorem 1.10. The proof is mainly adapted from [59]. For the convenience of the reader, we include the details. Write \( \mu = m \circ \pi^{-1} \). Since \( \mathcal{S} \) satisfies the strong separation condition, by Proposition 7.4 we have \( h_s = 0, h_m(\sigma) < \sum_{\ell=1}^{s}(-\lambda_\ell)k_\ell \) and \( \dim_{LY}(m, \mathcal{M}) < d \). Let \( i \) be the unique element in \( \{1, \ldots, s\} \) so that \( d_{i-1} \leq \dim_{LY}(m, \mathcal{M}) < d_i \). (Recall that \( d_0 = 0 \) and \( d_j = k_1 + \cdots + k_j \) for \( j \geq 1 \).) By Definition 7.1, we have \( h_m(\sigma) \in [L_{i-1}, L_i) \) where \( L_0 := 0 \) and \( L_j := -\sum_{\ell=1}^{i} \lambda_\ell k_\ell \) for \( j \geq 1 \). Below we prove the equality \( \dim_H \mu = \dim_{LY}(m, \mathcal{M}) \) under the assumption that one of the scenarios (a), (b), (c) occurs.

We first consider the scenario (a). In this case, \( s = 1 \) and by Theorem 1.3,
    \[
    \dim_H \mu = \frac{h_1 - h_0}{\lambda_1} = \frac{-h_m(\sigma)}{\lambda_1} = \dim_{LY}(m, \mathcal{M}).
    \]

Next we consider the scenario (b). In this case, \( i = s \) and so \( h_m(\sigma) \in [L_{s-1}, L_s) \). To show that \( \dim_H m \circ \pi^{-1} = \dim_{LY}(m, \mathcal{M}) \), it suffices to show that
    \[
    (8.4) \quad h_{s-1} = h_m(\sigma) + k_1\lambda_1 + \cdots + k_{s-1}\lambda_{s-1}.
    \]

Indeed if (8.4) holds, then \( h_0 - h_{s-1} = \sum_{\ell=1}^{s-1}(-\lambda_\ell)k_\ell \), which forces that \( h_j - h - j = (-\lambda_j)k_j \) for \( 1 \leq j \leq s - 1 \) (recalling that \( h_j - h_j = (-\lambda_j)k_j \) for all \( j \) by Corollary 6.1); hence
    \[
    \sum_{\ell=1}^{s-1} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} = d_{s-1},
    \]
so (7.1) holds for \( j = s - 1 \), then by Proposition 7.4, we obtain that \( \dim_H \mu = \dim_{LY}(m, \mathcal{M}) \).

To show (8.4) we first prove that
    \[
    (8.5) \quad h_{s-1} \geq h_m(\sigma) + k_1\lambda_1 + \cdots + k_{s-1}\lambda_{s-1}.
    \]

To see this, replacing \( \mathcal{S} \) by one of its iterations if necessary, we may assume that \( ||M_j|| < 1/2 \) for all \( j \in \Lambda \). By Theorem 1.9 in [40], for \( \mathcal{L}^{d|\Lambda}| \)-a.e. \( a \in \mathbb{R}^{d|\Lambda} \), \( \dim_H m \circ (\pi_a)^{-1} = \dim_{LY}(m, \mathcal{M}) \). Hence by Proposition 7.2, for \( \mathcal{L}^{d|\Lambda}| \)-a.e. \( a \in \mathbb{R}^{d|\Lambda} \), \( h_{s-1,a} = h_m(\sigma) + k_1\lambda_1 + \cdots + k_{s-1}\lambda_{s-1} \). Since \( h_{s-1,a} \) is upper semi-continuous in \( a \) by Theorem 1.8, it follows that \( h_{s-1,a} \geq h_m(\sigma) + k_1\lambda_1 + \cdots + k_{s-1}\lambda_{s-1} \) for all \( a \in \mathbb{R}^{d|\Lambda} \). This proves (8.5).

Now suppose on the contrary that (8.4) does not hold. Then by (8.5), there exists \( \delta > 0 \) such that \( h_{s-1} = h_m(\sigma) + k_1\lambda_1 + \cdots + k_{s-1}\lambda_{s-1} + \delta \). By Theorem 1.6 (iii), for
$$m \circ (\Pi_{s-1})^{-1} \text{-a.e. } W \in G(d, d - d_{s-1}),$$

$$\dim_H \mu \circ (P_{W^\perp})^{-1} \leq \sum_{\ell=1}^{s-1} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}}$$

$$= \dim_H \mu - \frac{h_s - h_{s-1}}{\lambda_s}$$

$$= \dim_H \mu - \frac{h_{s-1}}{(-\lambda_s)}$$

$$= \dim_H \mu + d_{s-1} - \dim_{LY}(m, M) - \delta/(-\lambda_s),$$

where in the last equality, we use the fact that

$$\dim_{LY}(m, M) = d_{s-1} + \frac{h_0 - L_{s-1}}{(-\lambda_s)} = d_{s-1} + \frac{h_{s-1} - \delta}{(-\lambda_s)}.$$

Let $Y$ denote the set of $W \in G(d, d - d_{s-1})$ such that

$$\dim_H \mu \circ (P_{W^\perp})^{-1} \leq \dim_H \mu + d_{s-1} - \dim_{LY}(m, M) - \delta/(-\lambda_s).$$

Then $m \circ (\Pi_{s-1})^{-1}(Y) = 1$, so by (1.12),

$$\dim_H Y \geq \dim_H m \circ (\Pi_{s-1})^{-1}$$

(8.6)

$$\geq d_{s-1}(d - d_{s-1}) + d_{s-1} - \dim_{LY}(m, M).$$

On the other hand, we can get an upper bound estimate for $\dim_H Y$ by using Lemma 8.3. Indeed, if $\dim_H \mu \leq d_{s-1}$, then by Lemma 8.3(i) applied to $k = d_{s-1}$ and $t = \dim_H \mu + d_{s-1} - \dim_{LY}(m, M) - \delta/(-\lambda_s)$, we see that

$$\dim_H Y \leq d_{s-1}(d - d_{s-1}) + \dim_H \mu - \dim_{LY}(m, M) - \delta/(-\lambda_s)$$

$$\leq d_{s-1}(d - d_{s-1}) + d_{s-1} - \dim_{LY}(m, M) - \delta/(-\lambda_s);$$

Conversely if $\dim_H \mu > d_{s-1}$, then by Lemma 8.3(ii) applied to $k = d_{s-1}$ and $t = \dim_H \mu + d_{s-1} - \dim_{LY}(m, M) - \delta/(-\lambda_s)$, we get the same upper bound for $\dim_H Y$, which contradicts with (8.6). This proves (8.4).

Finally we consider the scenario (c). In this case, $h_m(\sigma) \in [L_{i-1}, L_i)$. Clearly the assumptions (1.13)-(1.14) imply that

$$d_{i-1} \leq \dim_H \mu \leq \dim_{LY}(m, M) \leq d_i.$$

To prove $\dim_H \mu = \dim_{LY}(m, M)$, by Proposition 7.4 it suffices to prove that

$$\sum_{\ell=1}^{i-1} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = d_{i-1} \quad \text{and} \quad \sum_{\ell=i+1}^{s} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = 0.$$

As $d_0 = 0$, the first equality holds automatically when $i = 1$.

Now we first prove that

$$\sum_{\ell=1}^{i-1} \frac{h_{\ell} - h_{\ell-1}}{\lambda_{\ell}} = d_{i-1}. \quad \text{To avoid triviality, we assume that } i \geq 2.$$

For $n \in \mathbb{N}$, let $X_n$ denote the set of $W \in G(d, d - d_{i-1})$ so that $\dim_H \mu \circ (P_{W^\perp})^{-1} \leq d_{i-1} - 1/n$. By Lemma 8.3(ii) applied to $k = d_{i-1}$ and $t = d_{i-1} - 1/n$,

$$\dim_H X_n \leq d_{i-1}(d - d_{i-1}) + d_{i-1} - (1/n) - \dim_H \mu$$

$$< \dim_H m \circ (\Pi_{i-1})^{-1} \quad \text{(by (1.14))}.$$
It follows that \( m \circ (\Pi_{i-1})^{-1}(X_n) < 1 \) and hence \( \dim_H m \circ (P_{W^+})^{-1} > d_{i-1} - 1/n \) on a set of positive \( m \circ (\Pi_{i-1})^{-1} \)-measure. However by Theorem 1.6(iii),

\[
\dim_H m \circ (P_{W^+})^{-1} \leq \sum_{\ell=1}^{i-1} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} \quad \text{for } m \circ (\Pi_{i-1})^{-1}\text{-a.e. } W.
\]

It follows that \( \sum_{\ell=1}^{i-1} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} \geq d_{i-1} - 1/n \). As \( n \) is arbitrary, we obtain that \( \sum_{\ell=1}^{i-1} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} \geq d_{i-1} \). Since \( h_{\ell-1} - h_\ell \leq (-\lambda_\ell)k_\ell \) for each \( \ell \) by Corollary 6.1, we have \( \sum_{\ell=1}^{i-1} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} = d_{i-1} \), as desired.

Next we prove that \( \sum_{\ell=i+1}^{s} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} = 0 \). For \( n \in \mathbb{N} \), let \( Z_n \) denote the set of \( W \in G(d, d - d_i) \) so that \( \dim_H (P_{W^+})^{-1} \leq \dim_H m - 1/n \). By Lemma 8.3(i) applied to \( k = d_i \) and \( t = \dim_H m - 1/n \),

\[
\dim_H Z_n \leq d_i (d - d_i) - d_i + \dim_H m - (1/n) \\
\leq d_i (d - d_i) - d_i + \dim_L (m, M) - (1/n) \\
< \dim_H^* m \circ (\Pi_i)^{-1} \quad \text{(by (1.13))}.
\]

Hence \( m \circ (\Pi_{i-1})^{-1}(Z_n) < 1 \) and so \( \dim_H m \circ (P_{W^+})^{-1} > \dim_H m - 1/n \) on a set of positive \( m \circ (\Pi_{i-1})^{-1} \)-measure. This combining with (8.7) (in which we replace \( i - 1 \) by \( i \)) yields that \( \sum_{\ell=1}^{i} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} \geq \dim_H m - 1/n \). Letting \( n \to \infty \) gives \( \sum_{\ell=1}^{i} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} \geq \dim_H m \), which, together with (1.6), implies that \( \sum_{\ell=i+1}^{s} \frac{h_\ell - h_{\ell-1}}{\lambda_\ell} = 0 \). This completes the proof of the theorem. \( \square \)
