Abstract

We explore leptoquark production and decay for the $\tilde{R}_2$ class of models at the proposed $e^-p$ collider LHeC, planned to operate with 150 GeV electron and 7 TeV proton beams. In addition to the coupling of leptoquark with the lepton and jet, the model also has right handed neutrinos, coupled to the leptoquark. We analyse the collider signatures of a number of final states, that can originate from leptoquark decay into the standard model particles, as well as, the final states that originate from further decay of the heavy neutrinos, produced from leptoquark. We find that the final state $\ell^- + n$-jets ($1 \leq n \leq 2$) has the largest discovery prospect, more than $5\sigma$ with only few fb of data to probe a leptoquark of mass 1.1 TeV, even with a generic set of cuts. The significance falls sharply with increasing leptoquark mass. However, with 100 fb$^{-1}$ of data, a $5\sigma$ discovery for leptoquarks of mass upto 1.4 TeV is still achievable. Also for the same luminosity, final state $b\ell^+\tau^- + n$-jets ($n \geq 2$) + $E_T$, resulting from the cascade decay of the leptoquark to an $\tilde{t}$ and right handed neutrino, followed by further decays of $\tilde{t}$ and the neutrino, is expected to yield a rather large number of events ($\approx 180$).
I. INTRODUCTION

Discovery of physics beyond the Standard Model (SM) continues to be the aim of most high energy physicists today. Inspite of the so far unsuccessful direct searches for new particles or clear indications for existence of any kind of new physics at the Large Hadron Collider (LHC), issues of existence of dark matter, baryon asymmetry of the universe, non-zero neutrino masses etc., are compelling enough for one to believe that there must exist physics beyond the SM. A number of beyond Standard Model extensions have been proposed in the literature. Minimal supersymmetric standard model, large extra dimensions, seesaw models of neutrino mass generation, leptoquarks and grand unified theories, are a few among them.

Leptoquarks (LQs) are hypothetical particles, which make leptons couple directly to quarks and vice versa [1–3]. In the Pati-Salam model, they emerged from the unification of quarks and leptons [4]. They also exist in grand unification theories based on SU(5) [5] and SO(10) [6–15]. They are also expected to exist at TeV scale in extended technicolour models [16–19]. LQs can be either of scalar or vector nature. Using the SM representation of quarks and leptons, all possible LQ states can be classified, with six scalar and six vector LQ multiplets under the SM gauge group [20]. Among the different classes, the scalar LQ $\tilde{R}_2$ is interesting, as it is one of the multiplets that allows for matter stability [21]. Moreover, it also couples to right handed neutrinos (RH neutrinos). The RH neutrinos can generate light neutrino masses through seesaw mechanism [22–35]. In seesaw, light neutrino masses are generated through $d = 5$ lepton number violating operator [28]. The high scale UV completed models include gauge singlet RH neutrino (type-I, inverse seesaw), $SU(2)_L$ triplet scalar and fermion (type-II, and type-III).

In the case of type-I seesaw [22–25], the light neutrinos acquire masses through mixings with additional Majorana RH neutrinos. To account for the tiny neutrino masses, the mass scale of these Majorana neutrinos has to be very close to the gauge coupling unification scale, in which case these massive RH neutrinos will remain inaccessible at LHC as well as, at other near future colliders. For the present and near future colliders to be able to probe the RH neutrinos, their masses have to be within the experimental reach, and the mixing with the active-neutrinos (referred as active-sterile mixing) has to be sizable. TeV scale RH neutrinos with substantially large active-sterile mixings are however possible to accommodate in type-
I see-saw if cancellation exists in the light neutrino mass matrix [36]. The inverse see-saw mechanism [33–35] is another such scenario, where TeV scale or even smaller RH neutrino masses with sizeable active-sterile mixing can exist. In this scheme, in addition to the SM particles there are gauge singlet neutrinos, with opposite lepton numbers (+1 and -1). The light neutrino mass matrix is given in terms of the Dirac neutrino mass term, \( m_D \sim Y_{\nu} v \) (with \( v \) being the electroweak vev and \( Y_{\nu} \), a generic Yukawa coupling), the heavy neutrino mass scale \( M_R \) and, a small lepton number violating (\( \Delta L = 2 \)) mass term \( \mu \), which ensures that \( M_R \) scale remains close to TeV or less, with order one Yukawa coupling. The light neutrino mass matrix in this case is: \( m_{\nu} \sim (m_D^2/M_R^2)\mu \). While the heavy neutrino states may lie within the kinematic reach of LHC, their production cross section falls rapidly with increasing masses and smaller active-sterile neutrino mixing. Large active-sterile mixing is possible to obtain in other see-saw scenarios as well, such as, linear see-saw [37, 38], extended see-saw [39–43]. A substantial rise in the production cross section of the RH neutrinos is feasible in the presence of LQs. This has been explored recently for LHC in [44] for inverse see-saw, where a number of final states have been analysed in detail. Leptoquark models have also been tested recently for fitting the IceCube events [45]. For the heavy neutrino searches at LHeC in inverse see-saw model, see [46] and for the LNV signal at LHeC, see [47]. Similar studies for heavy neutrino searches also been carried out in [48, 49].

In this work, we consider a particular type of scalar leptoquark \( \tilde{R}_2 \) which transforms as \( \tilde{R}_2 \in (3, 2, \frac{1}{6}) \) under the SM gauge group \( SU(3)_c \times SU(2)_L \times U(1)_Y \) and for the RH neutrino, we adopt model independent framework. \( \tilde{R}_2 \) is a genuine LQ with fermion number \( F = 3B + L = 0 \). The colour charge of the LQ will enable in their copious production at LHC. Moreover, at \( e^-p \) colliders like LHeC, they can be resonantly produced. The LHeC is a proposed \( e^-p \) collider in the TeV regime after HERA, supposed to be built in the LHC tunnel [50]. LHeC will use a newly built electron beam of 60 GeV, up to possibly 150 GeV, to collide with the intense 7 TeV proton beam of the LHC. LHeC is expected to operate with 100 fb\(^{-1}\) integrated luminosity, and is complementary to the \( pp \) collider LHC [51]. The RH neutrino, being coupled to the LQ, can be produced from LQ decay. The decay of LQ into a lepton and a jet, and the decay of RH neutrino in different SM states give rise to a plethora of model signatures, that we study in detail. We show that among all the final states, \( \ell^- + n\text{-jets}(1 \leq n \leq 2) \) has the highest LQ discovery prospect, even with generic sets of cuts. Additionally, we also carry out an in-depth analysis for few other channels that arise
due to the decay of a heavy neutrino. We show that with judiciously applying selection cuts
the channels $\ell^- + n$-jets($n \geq 3$), and $\ell^+\tau^-\bar{b} + E_T + n$-jets($n \geq 2$) can be made background
free.

The discussion of the paper goes as follows: in Section. II and Section. III, we review
the model and the theory constraints. Following that, in Section. IV, we discuss the pro-
duction and decay of LQ at LHeC. In the subsequent sections, Section. V, Section. VI and
Section. VII, we present a detailed collider analysis and discuss the discovery prospects of
different final states. Finally, in Section. VIII, we summarize.

II. MODEL

We consider the scalar LQ $\tilde{R}_2$ charged as $(3,2,1/6)$ under SM gauge group. In the presence
of the RH neutrinos $N_R$, the LQ has additional interaction \[2, 3, 20\],

$$
\mathcal{L} = -Y_{ij} \bar{d}_R^i \tilde{e}_L^j \tilde{R}_2^a \epsilon^{ab} L_L^b + Z_{ij} \bar{Q}_j^i \tilde{R}_2^a N_R^j + h.c., \tag{1}
$$

where $i, j = 1, 2, 3$ are flavor indices and $a, b = 1, 2$ are $SU(2)_L$ indices. We assume that there
are three right-chiral neutrinos $N_R^j (j = 1, 2, 3)$, $Y_{ij}$ and $Z_{ij}$ are the elements of arbitrary
complex $3 \times 3$ Yukawa coupling matrices. Note that, $\tilde{R}_2$ comprises two LQs. One has $Q = 2/3$, and
the other has $Q = -1/3$. Upon expansion, the Lagrangian becomes

$$
\mathcal{L} = -Y_{ij} \bar{d}_R^i \tilde{e}_L^j \tilde{R}_2^{2/3} + (Y_{PMNS})_{ij} \bar{u}_L^i \tilde{R}_2^{-1/3} +
(V_{CKM} Z)_{ij} \bar{u}_L^i N_R^j \tilde{R}_2^{2/3} + Z_{ij} \bar{d}_L^i N_R^j \tilde{R}_2^{-1/3} + h.c., \tag{2}
$$

where the superscript of LQ fields denotes electric charge of a given $SU(2)_L$ doublet compo-
nent of $\tilde{R}_2$, $U_{PMNS}$ and $V_{CKM}$ are Pontecorvo-Maki-Nakagawa-Sakata (PMNS) and Cabibbo-
Kobayashi-Maskawa (CKM) matrices. At the $e^- p$ machine $\tilde{R}_2^{3/2}$ can not be resonantly pro-
duced. Hence, the expected cross-section for the production of $\tilde{R}_2^{3/2}$ is small. Therefore, in
this work, we consider only $\tilde{R}_2^{3/2}$ and study its production.

The charged current and neutral current interactions of the RH neutrinos are parametrized
in a model independent way as follows,

$$
-\mathcal{L}_{CC} = \frac{g}{\sqrt{2}} W^-_{\mu} \bar{\ell} \gamma^\mu P_L V_{ij} N_j + H.c., \tag{3}
$$
and

\[-\mathcal{L}_{NC} = \frac{g}{2\cos\theta_w} Z_\mu \left\{ (U^\dagger_{PMNS} V)_{ij} \bar{\nu}_i \gamma^\mu P_L N_j + \text{H.c.} \right\} \] (4)

The interaction of the heavy neutrinos with Higgs has the following form:

\[-\mathcal{L}_H = \frac{g M_j}{4 M_W} H \left\{ (U^\dagger_{PMNS} V)_{ij} \bar{\nu}_i P_R N_j + \text{H.c.} \right\} \] (5)

In the above \( P_{L/R} = (1 \mp \gamma^5)/2 \) is the left/right-chirality projection operator, and \( V \) is the mixing matrix through which light neutrinos mix with the RH neutrinos, and referred to as active-sterile mixing. We consider a diagonal basis for the charged leptons.

For the RH neutrino, coupled with LQ, we do not assume any particular model. Instead, we are interested in different frameworks of RH neutrinos, that can lead to large active-sterile mixing, so that the heavy neutrinos decay inside the detector. It is widely known, that a number of different frameworks can generate large active-sterile mixing, including inverse and linear seesaw [33–35, 37, 38], extended seesaw [39–43], cancellation framework [36]. In the inverse seesaw, light SM neutrino masses are extremely tiny, owing to the small lepton number violating parameter of the model. The active-sterile neutrino mixing is not constrained from light neutrino masses in this model. Active-sterile mixing upto \( \mathcal{O}(10^{-2}) \) is allowed from experimental data [52–59]. In extended seesaw, or double seesaw [60], the RH neutrino gets mass due to seesaw, and light neutrino masses are generated due to two-fold seesaw. In other frameworks, such as, cancellation, small light neutrino masses are generated due to cancellation between different RH neutrino contributions in the mass matrix [36]. The active-sterile mixing is yet unconstrained from neutrino data. In all the above mentioned frameworks, owing to the charged current and neutral current interactions as well as the interaction with the Higgs, specified above in Eqs.\((3),(4)\) and \((5)\), the RH neutrino \( N \) can decay to a number of SM particles, including \( l^\pm W^\mp, \nu Z, \) and \( \nu H \). The branching ratio of these three decays is \( \text{Br}(N \rightarrow lW) : \text{Br}(N \rightarrow \nu Z) : \text{Br}(N \rightarrow \nu H) \simeq 0.6 : 0.3 : 0.1 \), once RH neutrino mass becomes larger than the Higgs mass \( M_N > M_H \) and \( M_N < 200 \text{ GeV} \) [57, 61].

In the following sections, we first consider the resonant production of LQ and its decay to a lepton and jet. We next consider the production of heavy neutrinos from LQ decay, and discuss the discovery prospect of the LQ in a number of channels. As mentioned before, we consider the prompt decays of heavy neutrino for the analysis of the RH neutrino signature, that occurs due to large active-sterile neutrino mixing. We compare between the usual
charged current (CC) production of heavy neutrinos vs the alternate production from LQ decay. We show that the production from LQ decay dominates over the CC production mode by order of magnitude for active-sterile mixing $V \lesssim 10^{-2}$.

III. CONSTRAINTS ON LEPTOQUARK COUPLINGS

The couplings of the LQs to fermions are constrained by low energy precision observables such as atomic parity violation, Kaon decays etc. We assume that the Yukawa coupling matrix elements, $Y_{ij} = \delta_{ij}Y_i$ and $Z_{ij} = \delta_{ij}Z_i$, where, $i, j = 1, 2, 3$. Hence the LQ couples exclusively to a lepton and a quark of the same generation, although it can have non-zero couplings to fermions of more than one generation.

- LQs have been searched for and studied in the context of $e^+e^-$ [62–66], $ep$ [67–72], $pp$ [73–77], and $pp$ [78–83] colliders. The present tightest bounds are from the LHC [84–88]. LHC has studied the process $pp \rightarrow LQ LQ \rightarrow \ell j \ell j$ for LQs of first, second and third generations. Non-observation of any new physics at the LHC has ruled out LQs of masses up to 1.1 TeV at 95% C.L for the LQ decaying to $ej$ with 100% branching ratio [88]. For second generation, the bound is even more stringent $M_{LQ} > 1.5$ TeV at 95% C.L [88]. For third generation, the bound is $M_{LQ} > 900$ GeV at 95% C.L [87]. At

FIG. 1. Left panel: Feynman diagram for the gluon-initiated LQ pair-production process at LHC. Right panel: the same, but for the quark-initiated processes.

LHC, numerous QCD diagrams contribute to the LQ pair production. For illustration, we show only one representative gluon initiated diagram in the left panel of Fig. 1. However, with non-zero Yukawa couplings, significantly large contribution to the LQ...
pair production may arise through a singlet t-channel diagram (see the right panel of Fig. 1). The pair production cross-section at LHC can be parametrised as

\[ \sigma_{\text{pair}}(Y_{ii}, M_{LQ}) = a_0(M_{LQ}) + a_2(M_{LQ})|Y_{ii}|^2 + a_4(M_{LQ})|Y_{ii}|^4, \]

where the three terms correspond to the QCD pair production, an interference term and t-channel production. In Fig. 2, we show the variation of LQ pair production cross-section with the Yukawa coupling \( Y_{11} \).

![Graph showing variation of the production cross-section with Yukawa for \( \sqrt{s} = 13 \) TeV.](image)

**FIG. 2.** Left panel: variation of the production cross-section with Yukawa for \( \sqrt{s} = 13 \) TeV. Right panel: limit on scalar LQ pair-production times the branching fraction to eq final state as a function of mass for first-generation LQs. The yellow and green bands represent the 2\( \sigma \) and 1\( \sigma \) expected limits. The NLO prediction is shown in blue curve with uncertainty due to choice of PDF set and renormalisation/factorisation scale \[85\].

For small Yukawa coupling \( Y_{11} \), LQ pair production is mostly governed by QCD, as can be seen from the straight line up to \( Y_{11} \approx 0.5 \) in Fig. 2. For intermediate Yukawa couplings there exists a region with negative interference between QCD diagrams and the t-channel diagram where the total cross section decreases \[89\], resulting in the mild dip in the cross-section for coupling beyond 0.5, that is seen in Fig. 2. For large Yukawa coupling \( Y_{ii} \), the t-channel process dominates and significantly enhances the cross-section. The right panel of Fig. 2 shows the limit on the first-generation scalar LQ pair-production times the branching fraction to eq final state as a function of the mass. For the branching fraction \( LQ \to eq \) as 100%, the bound on the pair-production
of LQ becomes $\sigma(pp \to LQLQ) \lesssim 3$ fb, for LQ mass $1.1$ TeV. Comparing the left and right panel of Fig. 2, one can see that the limit on the cross section for a LQ of mass $1.1$ TeV, will be inconsistent with a Yukawa coupling larger than $1$.

It is obvious from Eq. 1 that for the LQ to have $100\%$ branching ratio in the $LQ \to ej$ decay mode, the coupling $Z$ needs to be zero. Allowing non-zero value for coupling $Z$ will open up new decay modes, such as $\bar{t}N$ for LQ, and hence will lower the stringent bound on LQs. We however, adopt a conservative approach, and in order to be consistent with the LHC results for first generation of LQ, throughout our study, we consider $M_{LQ} \geq 1.1$ TeV. Additionally, we also keep both the couplings non-zero.

- The present bound on coupling $Y$ from atomic parity violation are $Y_{de} < 0.34 \left(\frac{M_{LQ}}{1\text{TeV}}\right)$, $Y_{ue} < 0.36 \left(\frac{M_{LQ}}{1\text{TeV}}\right)$ [89]. These bounds are extracted under the assumption that only one of the two contributions is present at a given moment. These bounds allow large coupling for larger mass of LQ, and place a stringent constraint for lighter LQ.

- The most stringent bound on the diagonal couplings of $\tilde{R}_2^{2\frac{2}{3}}$ comes from LFV decay mode $K_L \to \mu^- e^+$, as this is a tree level process. Following Refs. [89, 90], the bound is given by, $|Y_{s\mu} Y_{de}^*| < 2.1 \times 10^{-5} \left(\frac{M_{LQ}}{1\text{TeV}}\right)^2$. In order to satisfy both the APV and LFV constraints, for $Y_{de} \sim O(0.1)$, the other coupling $Y_{s\mu}$ has to be tiny. We consider $Y_{s\mu}$ to be zero and a large value $(0.3)$ for $Y_{de}$ to get large production cross-section of LQ at LHeC.

We discuss the production of a LQ, and its decay to different final states in the next section, for the benchmark points, that are in agreement with the described constraints.

### IV. LEPTOQUARK PRODUCTION AND ITS DECAYS

At $e^- p$ colliders, scalar LQs can be resonantly produced through $s$-channel process as shown in the left panel of Fig. 3 and decay to a lepton and a jet. In addition, LQ can also be a $t$-channel mediator for the process $e^- p \to l^- j$, that we consider in our analysis (shown in the right panel of Fig. 3).

The production cross-section of a LQ at LHeC, as well as that for both the single and pair production at LHC, are shown in Fig. 4 for varying LQ mass. Clearly, the LHeC cross-section is more than both the pair-production, as well as, the single production of LQ.
associated with a charged lepton at LHC. The higher LQ production cross-section as well as the lower background at LHeC will allow more precise studies for probing LQ and RH neutrinos. Once produced, the LQ can decay into a number of final states, including, a) a quark-lepton pair that gives rise to single charged lepton and a light jet, b) a light jet and a heavy neutrino, and c) a top quark accompanied with a heavy neutrino. These heavy neutrinos appearing from the decays of the LQ can again be more easily probed at LHeC through its decay products. Note that, for all these processes, the LQ can also mediate as $t$-channel mediator. For b) and c), there is also $t$-channel contribution from $W$ gauge boson mediator, but significantly smaller for the active-sterile mixing $V \lesssim 10^{-2}$. We give numerical estimates in Section. VI. However, during computation (in Fig. 5 and for the collider analysis), we consider all the contributions together.

![Feynman diagram for $e^-p \rightarrow \ell j$.](image)

**FIG. 3.** Feynman diagram for $e^-p \rightarrow \ell j$.  

![Comparison of the cross section for LQ production at LHC and at LHeC. The c.m. energy for LHC is $\sqrt{s} = 13$ TeV. For LHeC, we use electron beam of 150 GeV and proton beam of 7 TeV, respectively. The coupling $Y_{de}$ has been set to 0.3, in agreement with the experimental constraints.](image)

**FIG. 4.** Comparison of the cross section for LQ production at LHC and at LHeC. The c.m. energy for LHC is $\sqrt{s} = 13$ TeV. For LHeC, we use electron beam of 150 GeV and proton beam of 7 TeV, respectively. The coupling $Y_{de}$ has been set to 0.3, in agreement with the experimental constraints.

For our computations, the LQ mass has been set to 1.1 TeV. We choose three benchmark
TABLE I. Benchmark parameters and production cross-section for $\ell j$, $jN_1$ and $\bar{t}N_3$ at LHeC with electron and proton beam energy 150 GeV and 7 TeV respectively. LQ mass is considered as 1.1 TeV.

| Benchmarks | $M_{N_{1,3}}$ | $Y$ | $Z$ | Process | $\sigma_{XY}$ (fb) |
|------------|--------------|-----|-----|---------|------------------|
| BP1        | (150, 1000, 1000) | (0.3, 0, 0) | (0, 0, 0) | $\ell j$ | 221               |
| BP2        | (150, 1000, 1000) | (0.3, 0, 0) | (1, 0, 0) | $jN_1$   | 242               |
| BP3        | (1000, 1000, 150)  | (0.3, 0, 0) | (0, 0, 1) | $\bar{t}N_3$ | 222               |

points, with the three heavy neutrino masses and the LQ couplings, $Y_{ii}$ and $Z_{ii}$ chosen such that they are consistent with all the constraints mentioned in Sec. III as well as with the neutrino oscillation data [46]. These parameters for the benchmark points have been specified in Table [I]. The production cross-section for these three processes at LHeC, with electron and proton beam energies of 150 GeV and 7 TeV respectively, are also shown in Fig. 5 as a function of the couplings.

The general expression for the two body decay of a scalar LQ to $\ell_i q$ and $N_i q$ final states are given by,

$$\Gamma(LQ \rightarrow \ell_i q) = \frac{|Y_{ii}|^2}{16\pi M_{LQ}^3} \lambda^\frac{1}{2}(M_{LQ}^2, m_{\ell_i}^2, m_{q}^2)(M_{LQ}^2 - m_{\ell_i}^2 - m_{q}^2)$$  \hspace{1cm} (7)

$$\Gamma(LQ \rightarrow N_i q) = \frac{|Z_{ii}|^2}{16\pi M_{LQ}^3} \lambda^\frac{1}{2}(M_{LQ}^2, M_{N_i}^2, m_{q}^2)(M_{LQ}^2 - M_{N_i}^2 - m_{q}^2)$$  \hspace{1cm} (8)

In the massless limit of leptons and quarks, the branching ratios are given by,

$$\beta(LQ \rightarrow \ell_i q) = \frac{|Y_{ii}|^2}{\sum_i(|Y_{ii}|^2 + |Z_{ii}|^2)} \quad \text{and} \quad \beta(LQ \rightarrow N_i q) = \frac{|Z_{ii}|^2}{\sum_i(|Y_{ii}|^2 + |Z_{ii}|^2)}$$  \hspace{1cm} (9)

At an $e^{-}p$ collider LQs can be resonantly produced, followed by their decay. Hence, we can write the cross section approximately as,

$$\sigma(e^{-}p \rightarrow \ell_i q \text{ or } N_i q) \approx \sigma(e^{-}p \rightarrow LQ) \cdot \beta(LQ \rightarrow \ell_i q \text{ or } N_i q).$$ \hspace{1cm} (10)

As can be seen, from Eq. [9] with increasing coupling $Z_{11}$ the branching ratio of $\sigma(e^{-}p \rightarrow jN_1)$ increases, while $\sigma(e^{-}p \rightarrow lj)$ decreases. This results in larger cross-section for $\sigma(e^{-}p \rightarrow jN_1)$ for larger $Z_{11}$. Cross section for the other channel $e^{-}p \rightarrow \bar{t}N_3$ is also large for large value of $Z_{33}$. The values of the cross-section in fb, for three benchmark points are given in the last column of Table. [I] As can be seen, the production cross-section at LHeC is fairly large,
approximately $\sigma \sim 221-242 \text{ fb}$ for the chosen benchmark points. As we will show in the next sections, folded with branching ratios of heavy neutrino, top quark, the total cross-section for the different final states will be sizeable.

![Graph](image1)

FIG. 5. Production cross-section for $\ell j$, $jN_1$ and $\bar{t}N_3$ at LHeC with varying coupling $Z_{11}$. We have considered 150 GeV electron beam colliding with 7 TeV Proton beam. The LQ mass has been set to 1.1 TeV. For $l^-j, jN_1$, the coupling $Y_{11} = 0.3$, $Z_{11}$ is varying and for $\bar{t}N_3$ production, the coupling $Y_{11} = 0.3$, $Z_{33}$ is varying, rest of the Yukawa coupling has been set to zero.

![Graph](image2)

FIG. 6. Production cross-section for $\ell j$, $jN_1$ and $tN_3$ with varying LQ mass $M_{LQ}$. For $l^-j, jN_1$ and $\bar{t}N_3$ production we adopt BP1, BP2 and BP3 respectively.
V. COLLIDER ANALYSIS

We implemented the model in FeynRules [91], generated the model files for MadGraph5_aMC@NLO (v2.5.5) [92] to calculate the parton level cross-section for signals and background. For the collider simulation part, we passed the MadGraph generated parton level events to PYTHIA (v6.4.28) [93], where subsequent decay, initial state radiation, final state radiation and hadronisation have been carried out. The jets are reconstructed by anti-$\kappa_t$ algorithm [94] implemented in Fastjet package [95] with radius parameter $R = 0.4$. For the analysis of signal and background events we use the following set of basic cuts,

1. Electrons and muons in the final state should have the following transverse momentum and pseudo-rapidity $p_T^{\ell} > 20$ GeV, $|\eta^{\ell}| < 2.5$.

2. Jets are ordered in $p_T$, jets should have $p_T^j > 40$ GeV and $|\eta^j| < 2.5$.

3. Photons are counted if $p_T^\gamma > 10$ GeV and $|\eta^\gamma| < 2.5$.

4. Jets should be separated by $\Delta R_{jj} > 0.5$.

5. Leptons should be separated by $\Delta R_{\ell\ell} > 0.2$.

6. Leptons and photons isolation $\Delta R_{\ell\gamma} > 0.2$.

7. Jets and leptons should be separated by $\Delta R_{\ell j} > 0.4$.

8. Hadronic activity within a cone of radius 0.3 around a lepton must be limited to $\sum p_T^{\text{hadron}} < 0.2p_T^{\ell}$, where $p_T^{\ell}$ is the transverse momentum of lepton within the specified cone.

Due to the initial and final state radiations, additional jets will be present in the final states considered. For the inverse seesaw framework, lepton number violation (LNV) is dictated by the parameter $\mu_X$, that is negligibly small. Therefore, the cross-section for LNV di-lepton final states will be suppressed. For the framework where light neutrino masses are generated as a result of cancellation, sizable lepton number violation can however be present. Below, we adopt a conservative approach, and only consider lepton number
conserving signatures. A number of signatures, including single lepton and multi-jet, di-lepton associated with multi-jet and missing energy, and multi-lepton associated with missing energy and $b$-jet have been analysed in the subsequent sections.

VI. SIGNALS AND BACKGROUND

A. Signal I : $\ell^- + n$-jets ($1 \leq n \leq 2$)

The single-lepton associated with jet is the easiest channel to probe LQ. LQ, once produced resonantly, can directly decay to a charged-lepton and a jet. Additionally, the $t$-channel contribution, as shown in Fig. 3 will also be present. The parton-level final state are therefore $\ell^- + n$-jets ($n = 1$). Additional jets will be present due to ISR, FSR. We demand the final state should contain $\ell^-$ and number of jets $1 \leq n$-jets $\leq 2$. The main backgrounds arise from SM process, such as, $e^- p \rightarrow \ell^- j$, $\ell^- jj$, that is significantly larger as compared to the signal. From Tab. II the signal cross-section is 220 fb, while the background cross-section is $3 \times 10^6$ fb. We use a number of cuts on different kinematic variables to reduce the background.

In Fig. 7 we have shown the transverse momentum of the leading lepton, leading and subleading jet, as well as the invariant mass distribution of the leading jet and leading lepton, both for the signal and background. Evidently, for a very heavy LQ, a high-$p_T$ cut on leading jet or lepton, and LQ invariant mass-cut will reduce SM background drastically.

In Table. II we have shown how we can reduce the SM background to zero using $p_T$ cuts - $p_T^{\ell^-}$ ($> 400$ GeV) on leading lepton and invariant mass cut - $|M_{LQ} - M_{\ell_1j_1}| \leq 100$ GeV simultaneously after using the basic sets of cuts mentioned in the previous section.

| Cuts                               | Final States            | Signal (fb) | Background (fb) |
|------------------------------------|-------------------------|-------------|-----------------|
| No cuts                            | $\ell^- + n$-jets($1 \leq n \leq 2$) | 220         | $2.96 \times 10^6$ |
| Basic cuts                         | $\ell^- + n$-jets($1 \leq n \leq 2$) | 159         | $4.08 \times 10^5$ |
| Leading lepton $p_T$ cut           | $+p_T^{\ell^-}$ ($> 400$ GeV) | 118         | 178             |
| LQ invariant mass cut              | $+|M_{LQ} - M_{\ell_1j_1}| \leq 100$ GeV | 101         | 0               |

B. Signal II

If the coupling $Z_{ij}$ is non-zero, the LQ can also decay to RH neutrino and a jet, as shown in the right panel of Fig. 8. The considered final state, can also arise from the $t$-channel $W$ exchange diagram as shown in left panel of Fig. 8. For active-sterile mixing $V \sim 10^{-2} - 10^{-3}$, the contribution from LQ however dominates. For example, with the BP2, the CC production cross section is $\approx 12.7$ fb, while the production cross section from LQ decay is $\approx 240$ fb. The subsequent decays of RH neutrino, followed by hadronic and leptonic decays of gauge bosons gives rise to a number of partonic states, that we list below.

1. $\ell^- + n$-jets ($n = 3$) (For hadronic decays of $W^+$)
FIG. 8. Feynman diagram for various final states from $e^-p \rightarrow jN$. For this case, t-channel LQ mediated diagram can also contribute.

2. $\ell^- + \ell^+ + n$-jets ($n = 1$) + $E_T$ (For leptonic decays of $W^+$)

1. $\ell^- + n$-jets ($n \geq 3$)

For the case of the hadronic decays of the charged gauge boson, we demand a charged lepton and at least three jets as final state. The invariant mass of the three jets and the charged lepton must be equal to that of the mass of the LQ. Hence a cut on the invariant mass distribution allows the separation of the signal from the background. For the background we generate $e^-p \rightarrow l^- + n$-jets upto $n = 3$. The distribution is given in the top left panel of Fig. 9. Additionally, the leading jet that is directly generated from LQ decay has a very high transverse momentum (see Fig. 9). Therefore, a large cut on the transverse momentum of the leading jet reduces the background. As can be seen from Table III, the large $p_T$ cut on the leading jet itself reduces the background by $\mathcal{O}(10^4)$. Further reduction in background is achieved though a cut on the invariant mass distribution of the heavy neutrino. Stringent cuts, such as, the cuts on the invariant mass of the LQ and the heavy neutrino make the background negligibly small.

2. $\ell^- \ell^+ + n$-jets ($n \geq 1$) + $E_T$

For the scenario, when charged gauge boson produced in the decay of RH neutrino, decays leptonically, the signal will have 2 opposite sign charged leptons, jets (one or more) and missing energy. The dominant SM background comes from the processes like $e^-p \rightarrow \ell^-\ell^+j\nu_\ell$ and $e^-p \rightarrow \ell^-\ell^+jj\nu_\ell$. The reduction of the background in this case is achieved through a cut on the missing energy and the cut on effective mass $M_{EFF}$. The $M_{EFF}$ variable is defined
FIG. 9. Invariant Mass distribution of LQ, $p_T$ distribution of leading, sub leading jet, and of leading lepton. We also show the invariant mass distribution of $N$ for the final state $\ell^- + n$-jets ($n \geq 3$).

As,

$$M_{EFF} = \sum_{i} p_{T_i}^j + \sum_{i} p_{T_i}^\ell + \not{E}_T,$$

where $p_{T_i}^j$, $p_{T_i}^\ell$ are the transverse momentum of the jet and lepton, and $\not{E}_T$ is the missing transverse energy. We expect a hard distribution for $M_{EFF}$, since the $p_T$ of the lepton and
| Cuts                        | Final States                  | Signal (fb) | Background (fb) |
|-----------------------------|-------------------------------|-------------|-----------------|
| No cuts                     | $\ell^-$+n-jets($n \geq 3$)  | 24.8        | $2.99 \times 10^6$ |
| Basic cuts                  | $\ell^-$+n-jets($n \geq 3$)  | 7.65        | $2.9 \times 10^3$  |
| Leading Jet $p_T$ cut       | $p_T^{j_1} (> 200\text{GeV})$ | 6.56        | 180             |
| LQ invariant mass cut       | $|M_{LQ} - M_{\ell j_1 j_2 j_3}| \leq 100\text{GeV}$ | 3.65        | 60              |
| $N$ invariant mass cut      | $|M_{N_1} - M_{\ell j_a j_b}| \leq 30\text{GeV}$ | 3.08        | 0               |

TABLE III. Signal and Background cross-sections for the final state $\ell^- + n$-jets ($n \geq 3$) with cuts. BP2 has been used for this final state.

jets coming mostly from resonantly produced LQ (as the t-channel contribution is small) is significantly large. The peak of the $M_{E_{\text{FF}}}$ shifts towards higher values with increasing LQ mass. We have shown in Fig. 10 the missing energy $E_T$, $M_{E_{\text{FF}}}$, leading jet and leading lepton

FIG. 10. Missing transverse energy distribution, $M_{E_{\text{FF}}}$ distribution, $p_T$ distribution of leading jet, and leading lepton for the final state $\ell^- \ell^+ + n$-jets ($n \geq 1$) + $E_T$. 17
\( p_T \) distributions. The effect of different cuts on the signal and background cross-sections are given in Table IV.

| Cuts                 | Final States                          | Signal (fb) | Background (fb) |
|----------------------|---------------------------------------|-------------|-----------------|
| No cuts              | \( \ell^- \ell^+ + \text{n-jets}(n \geq 1) + \not E_T \) | 11.2        | 5.22 \times 10^2 |
| Basic cuts           | \( \ell^- \ell^+ + \text{n-jets}(n \geq 1) + \not E_T \) | 7.84        | 258             |

| \( M_{EFF} \) cuts  | \( +M_{EFF}(> 500\text{GeV}) \)       | 2.88        | 2.54            |

TABLE IV. Signal and Background cross-section after various cuts for the final state \( \ell^- \ell^+ + \text{n-jets}(n \geq 1) + \not E_T \). BP2 has been used for this final state.

C. Signal III

For the LQ mass more than \( M_N + M_t \), it can further decay to \( \bar{t}N_3 \), that enables a final state with large lepton or large jet multiplicity. The large lepton multiplicity is promising due to suppressed SM background. For the \( \bar{t}N_3 \) production channel, considering subsequent decays of \( N_3 \) and \( \bar{t} \), where \( N_3 \) is assumed to decay to \( \tau^\pm W^\mp \), following final states at parton-level are possible:

1. \( \bar{t}\ell^- \tau^- \ell^+ + \not E_T \) (For leptonic decays of both the \( W \) bosons, \( W^- \to \ell^- \nu \), \( W^+ \to \ell^+ \nu \)),

FIG. 11. Feynman diagram for various final states from \( e^- p \to \bar{t}N_3 \). For this case also, the \( t \)-channel mediated diagram with gauge boson and LQ will contribute.
(2) $\bar{b} \ell^ {-} \tau^- + \text{n-jets (n = 2)} + \slashed{E}_T$ (For the W boson decays, $W^- \rightarrow \ell^- \nu$ and $W^+ \rightarrow jj$),
(3) $\bar{b} \tau^- \ell^+ + \text{n-jets (n = 2)} + \slashed{E}_T$ (For the W boson decays, $W^- \rightarrow jj$ and $W^+ \rightarrow \ell^+ \nu$),
(4) $\bar{b} \tau^- + \text{n-jets (n = 4)}$ (For the W boson decays, $W^- \rightarrow jj$ and $W^+ \rightarrow jj$).

We do not consider the last final states in our study because of very small cross-section and very large SM background due to large jet multiplicity.

1. $\bar{b} \ell^- \tau^- \ell^+ + \slashed{E}_T$

For the final states involving $\tau$ and $b$, tagging can reduce the SM background significantly. We consider the $p_T$ for the $b$ and $\tau$ jets, as $p_T > 40$ GeV. In this work, we adopt a minimalistic approach and consider a flat 75% efficiency for $b$-tagging and 60% efficiency for $\tau$-tagging. Similar to the previous case, the $M_{\text{EFF}}$ distribution is hard due to the large missing energy and large transverse momenta of final state particles. For this signal, the most dominant SM background comes from the process $\bar{t} \ell^- W^+$, $\bar{t} Z \nu$ and $\bar{t} h \nu$ with $\bar{t} \rightarrow \bar{b} \tau^- \nu$, $W^+ \rightarrow \ell^+ \nu$, $Z \rightarrow \ell^+ \ell^-$, and $h \rightarrow \ell^+ \ell^-$. After applying the basic cuts only, SM background drops significantly. In addition, we use missing energy $\slashed{E}_T$, leading jet $p_T$ and $M_{\text{EFF}}$ distribution to further reduce the SM background.

| Cuts                          | Final States                  | Signal (fb) | Background (fb) |
|-------------------------------|-------------------------------|-------------|-----------------|
| No cuts                       | $\bar{b} \ell^- \tau^- \ell^+ + \slashed{E}_T$ | 1.57        | 0.323           |
| Basic cuts                    | $\bar{b} \ell^- \tau^- \ell^+ + \slashed{E}_T$ | 0.83        | $7.51 \times 10^{-3}$ |
| Missing energy cut            | $\bar{b} \ell^- \tau^- \ell^+ + \slashed{E}_T (> 100\text{GeV})$ | 0.502       | $4.46 \times 10^{-3}$ |
| Leading Jet $p_T$ cut         | $+p_T^j (> 100\text{GeV})$    | 0.476       | $2.16 \times 10^{-3}$ |
| $M_{\text{EFF}}$ cuts, b and $\tau$ tagging | $+M_{\text{EFF}} (> 500\text{GeV})$ | 0.21        | $7.7 \times 10^{-4}$ |

**TABLE V.** Signal and Background cross-section after various cuts for the final state $\bar{b} \ell^- \tau^- \ell^+ + \slashed{E}_T$. BP3 has been used for this final state.

2. $\bar{b} \ell^- \tau^- + \text{n-jets (n \geq 2)} + \slashed{E}_T$

For this case, due to large jet multiplicity, SM background is greater than the previous signal and the background mainly comes from the process $\bar{t} \ell^- W^+$. However, using missing
energy $\not{E}_T$, cuts on leading jet $p_T$ and $M_{EFF}$ distribution, the SM background can be reduced significantly.

| Cuts                        | Final States                                   | Signal (fb) | Background (fb) |
|-----------------------------|------------------------------------------------|-------------|-----------------|
| No cuts                     | $b\ell^-\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$ | 3.54        | 0.729           |
| Basic cuts                  | $b\ell^-\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$ | 1.457       | 2.18 $\times$ 10^{-2} |
| Missing energy cut          | $b\ell^-\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T(> 100\text{GeV})$ | 1.277       | 1.344 $\times$ 10^{-2} |
| Leading Jet $p_T$ cut       | $+p_T^{\not{E}}(> 100\text{GeV})$             | 1.226       | 7.65 $\times$ 10^{-3} |
| $M_{EFF}$ cuts, b and $\tau$ tagging | $+M_{EFF}(> 500\text{GeV})$              | 0.522       | 2.4 $\times$ 10^{-3} |

TABLE VI. Signal and Background cross-section after various cuts for the final state $b\ell^-\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$. BP3 has been used for this final state.

3. $b\ell^+\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$

For this final state, SM background is actually negligibly small at $e^-p$ collider for the beam energies considered.

| Cuts                        | Final States                                   | Signal (fb) | Background (fb) |
|-----------------------------|------------------------------------------------|-------------|-----------------|

| Basic cuts, b and $\tau$ tagging | $b\ell^+\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$ | 1.83        | 0               |

TABLE VII. Signal and Background cross-section after various cuts for the final state $b\ell^+\tau^- + \text{n-jets (n} \geq \text{2)} + \not{E}_T$. BP3 has been used for this final state.

VII. SIGNAL STRENGTH FOR HIGHER LQ MASS

Bound on LQs parameter space is expected to improve in future with increasing luminosity at LHC. Hence, we repeat our study for higher LQ masses. Though for higher LQ mass, we can allow for large yukawa coupling, we use the same coupling as for 1.1 TeV LQ mass to compare our result for different LQ masses. Using the same set of cuts for each final states as we did for LQ mass 1.1 TeV, we have calculated the cross-section for LQ mass of
1.2, 1.3, ...upto 1.7 TeV. The partonic cross-sections and the effect of different cuts is shown in Table. VIII and IX.

### A. Zero Background Case

First, we consider only final states for which the SM background is zero or can be reduced to zero using invariant mass cut of LQ and RH neutrinos. The SM background is practically zero, for final state, $b\ell^+\tau^- +$ n-jets ($n \geq 2$) + $E_T$. For the final state, $\ell^- +$ n-jets ($1 \leq n \leq 2$), using $p_T^\ell$ cut and LQ invariant mass cut (for corresponding LQ mass), the SM background can be reduced to zero. Similarly, for the final state, $\ell^- +$ n-jets ($n \geq 3$), selection cut on $p_T^j$, along with on LQ invariant mass, and invariant mass of RH neutrino can make the SM background negligibly small. The results are given in Table. VIII. We have also shown the cross section and number of events with 100 fb$^{-1}$ integrated luminosity as a function of LQ masses in Fig. 12. As can be seen, the cross-section for the $\ell^- +$ n-jets ($1 \leq n \leq 2$) channel is the largest, varies $10^2 - 0.42$ fb for a wide range of LQ mass. With 100 fb$^{-1}$ luminosity, this predicts $10^4$ number of events at LHeC. The other channel with jet multiplicity ($n \geq 3$) also offers a large cross-section, and large number of events $\mathcal{O}(10^2)$.

| Final States          | 1.1 TeV | 1.2 TeV | 1.3 TeV | 1.4 TeV | 1.5 TeV | 1.6 TeV | 1.7 TeV |
|-----------------------|---------|---------|---------|---------|---------|---------|---------|
| $\ell^- +$ n-jets ($1 \leq n \leq 2$) | 101     | 47.53   | 18.37   | 6.148   | 2.04    | 0.82    | 0.42    |
| $\ell^- +$ n-jets ($n \geq 3$) | 3.08    | 1.98    | 0.83    | 0.47    | 0.322   | 0.24    | 0.18    |
| $b\ell^+\tau^- +$ n-jets ($n \geq 2$) + $E_T$ | 1.83    | 0.74    | 0.29    | 0.12    | 0.06    | 0.03    | 0.02    |

TABLE VIII. Cross-sections (in fb) after all the cuts as a function of LQ mass.

### B. Non-Zero Background Case

For the final states, $\ell^- +$ n-jets ($1 \leq n \leq 2$) and $\ell^- +$ n-jets ($n \geq 3$), the SM background is non zero if we do not use the invariant mass of LQ and RH neutrino. Since, the LQ and RH neutrino masses are unknown, we do not implement the mass cut, rather in this section show the cross-sections with a very generic sets of cuts. Assuming LQ mass to be more than 1 TeV, all the other cuts which we considered can be easily applied. For the above two final states we applied cuts only on $p_T^\ell$ and $p_T^j$. For final states, $\ell^-\ell^+ +$ n-jets ($n \geq 1$) + $E_T$,
FIG. 12. Left panel: Signal cross-section as a function of LQ mass for different final states. Right panel: No of events with integrated luminosity 100 fb$^{-1}$.

\[ \bar{b}\ell^-\tau^- + \ell^+ + n\text{-jets (n} \geq 2) + \not{E_T} \] and \[ \bar{b}\ell^-\tau^- + n\text{-jets (n} \geq 2) + \not{E_T} \] we used the same cuts as in Tables. IV, V and VI respectively. We show the signal cross section and statistical significance with

integrated luminosity of 100 fb$^{-1}$ in Fig. 13. We also show the required luminosity to achieve 3$\sigma$ and 5$\sigma$ statistical significance in Fig. 14. The statistical significance has been calculated using the following expression:

\[ S_{\text{sig}} = \frac{S}{\sqrt{S + B}}, \]  

where, $S$ and $B$ denote the number of signal and background events, respectively.
FIG. 13. Left panel: The signal cross-section as a function of LQ mass for different final states. Right panel: the significance with 100 fb$^{-1}$ luminosity.

1. Results

We discuss the discovery prospect of LQ in the mass range 1.1-1.7 TeV at LHeC. The channel $\ell^- + n$-jets($1 \leq n \leq 2$) is the most promising. For the final states $\ell^- + n$-jets($1 \leq n \leq 2$), even with integrated luminosity 2 fb$^{-1}$, the statistical significance is 9.69$\sigma$ for the LQ of mass 1.1 TeV. To probe larger masses, higher luminosity is required. Assuming $L = 100 \text{ fb}^{-1}$, a 1.7 TeV LQ can be probed at 0.4$\sigma$. For this final state, 5$\sigma$ statistical significance can be probed for LQ mass range $[1.1 - 1.4]$, with integrated luminosity of 100 fb$^{-1}$.

For final state $\ell^- + n$-jets($n \geq 3$), with integrated luminosity 100 fb$^{-1}$, the statistical significance is 4.8$\sigma$ for LQ mass of 1.1 TeV, decreasing to 0.13$\sigma$ for a 1.7 TeV LQ.

For the final state $\ell^- \ell^+ + n$-jets($n \geq 1$) + $E_T$, with integrated luminosity 100 fb$^{-1}$, the statistical significance is 12$\sigma$ for a 1.1 TeV LQ, which decreases to 0.24$\sigma$ for a 1.7 TeV LQ. For this final state, 5$\sigma$ statistical significance can be probed only for LQ mass range $[1.1 - 1.2]$ TeV, with integrated luminosity 100 fb$^{-1}$.

For the final state $\bar{b}\ell^- \tau^- + E_T$, with integrated luminosity 100 fb$^{-1}$, the statistical significance is 4.5$\sigma$ for a 1.1 TeV LQ, which decreases to 0.3$\sigma$ for a 1.7 TeV LQ. For this final state, 5$\sigma$ statistical significance can be probed for LQ mass 1.1 TeV, with integrated luminosity 120 fb$^{-1}$. In spite of small SM background, as the signal cross section is itself small for higher LQ masses, its difficult to observe this final state for higher LQ masses.

For the final state $\bar{b}\ell^- \tau^- + n$-jets ($n \geq 2$) + $E_T$, with integrated luminosity 100 fb$^{-1}$, the
FIG. 14. The required luminosity to achieve 3σ (left panel) and 5σ (right panel) for different final states.

statistical significance is 7σ for a 1.1 TeV LQ, which decreases to 0.6σ for a 1.7 TeV LQ. For this final state, 5σ statistical significance can be probed only for LQ mass 1.1 TeV, with integrated luminosity 100 fb⁻¹. Again for this case also, signal cross section is small for higher LQ mass, hence difficult to probe higher mass regime. However, it may be noted that our estimates for the cross-sections for LQs of higher masses are rather conservative, as they have been computed, assuming the coupling to be the same as that for 1.1 TeV LQ, while higher values of couplings for larger LQ masses will be permissible.

VIII. CONCLUSIONS

In this work, we study the discovery prospect of $\tilde{R}_2$ class of LQ model at LHeC. The model contains two LQs with $Q = \frac{2}{3}$ and $Q = -\frac{1}{3}$. LQ with $Q = \frac{2}{3}$ can be copiously produced at LHeC, due to its interaction with the electron and down type quark. We study the production and its decay to different final states, including a lepton and a jet, a jet and a RH neutrino, and RH neutrino and a top quark. The typical production cross-section for $e^- p \rightarrow l_j j N_1, \bar{t} N_3$ are 221, 242, 222 fb for $M_{LQ} = 1.1$ TeV, $M_{N_1,3} = 150$ GeV, and the couplings $Y_{11} = 0.3, Z_{33} = 1$. The produced RH neutrino further decays and give a plethora of model signatures. For the RH neutrinos, we adopt a model independent framework, and a large active-sterile mixing to ensure its decay within the detector. For the LQs, the higher production cross-section as well as the lower backgrounds at LHeC result in a much higher
statistical significance for few of the signals studied.

We have analysed a number of final states, including $\ell^- + n$-jets ($1 \leq n \leq 2$), $\ell^\pm + n$-jets ($n \geq 3$), $\ell^\pm \ell^\mp + n$-jets ($n \geq 1$) + $\slashed{E}_T$, $b\ell^- \tau^- + \ell^+ + \slashed{E}_T$, $\bar{b}\ell^+ \tau^- + n$-jets ($n \geq 2$) + $\slashed{E}_T$. Among these, the model signature $\ell^- + n$-jets ($1 \leq n \leq 2$) arises due to the direct decay of LQ to a lepton and a jet. All the other final states arise due to the decay of LQ to a RH neutrino and a light jet, or to a RH neutrino and top quark, with successive decays of RH neutrino, and $t$ quark into SM states.

We find that, among all the above mentioned final states, $\ell^- + n$-jets ($1 \leq n \leq 2$) has the highest discovery prospect even after giving a generic set of cuts. A LQ of mass upto 1.4 TeV in this channel can be discovered at more than $5\sigma$ C.L. with 100 $fb^{-1}$ of data. The LQs will also result in the enhancement of the RH neutrino production in association with a light jet, or with top quark. If at LHeC the electron beam is polarized, the right handed neutrino–light jet production cross-section can substantially increase [46, 47]. We find that among all the final states $\ell^- + n$-jets($n \geq 3$), and $\bar{b}\ell^+ \tau^- + n$-jets($n \geq 2$) + $\slashed{E}_T$ are the most optimal, after implementing the selection cuts judiciously. With 100 fb$^{-1}$ integrated luminosity, for LQ mass 1.1 TeV, the expected number of events for the final states $\ell^- + n$-jets($n \geq 3$), and $\bar{b}\ell^+ \tau^- + n$-jets($n \geq 2$) + $\slashed{E}_T$ are $10^4$ and 180 respectively.
