Abstract
We show that when KP (Kadomtsev–Petviashvili) $\tau$ functions allow special symmetries, the discrete BKP equation can be expressed as a linear combination of the discrete AKP equation and its reflected symmetric forms. Thus the discrete AKP and BKP equations can share the same $\tau$ functions with these symmetries. Such a connection is extended to 4 dimensional (i.e. higher order) discrete AKP and BKP equations in the corresponding discrete hierarchies. Various explicit forms of such $\tau$ functions, including Hirota’s form, Gramian, Casoratian and polynomial, are given. Symmetric $\tau$ functions of Cauchy matrix form that are composed of Weierstrass $\sigma$ functions are investigated. As a result we obtain a discrete BKP equation with elliptic coefficients.

Keywords: discrete AKP, discrete BKP, symmetric tau function, solution, elliptic function

1. Introduction

The Kadomtsev–Petviashvili (KP) equation is one of the most famous $(2 + 1)$-dimensional integrable systems. In discrete case, the discrete AKP (dAKP) equation and BKP (dBKP) equation are two master equations in the KP family. With parameterised coefficients, they are, respectively,

\begin{equation}
A \equiv (a - b)\widehat{\tau} + (b - c)\widehat{\tau} + (c - a)\widehat{\tau} = 0,
\end{equation}
written out from those of the continuous AKP and BKP equation (cf. [5]) by means of Miwa’s transformation [12]. Let us present these solutions by the following uniform formula, [16–18], and both equations are 4D consistent [1, 2].

\[ B = (a - b)(b - c)(c - a)\pi + (a - b)(a + c)(b + c)\pi + (b - c)(b + a)(c + a)\pi + (c - a)(c + b)(a + b)\pi = 0. \quad (2) \]

Here \( a, b, c \) are spacing parameters and tilde, hat, bar serve as notations of shifts in different directions (see (12)). An alternative form of equation (1) is

\[ c(a - b)\pi + a(b - c)\pi + b(c - a)\pi = 0, \quad \text{(3)} \]

which is connected with (1) by changing

\[ (a, b, c) \rightarrow (1/a, 1/b, 1/c). \quad \text{(4)} \]

Note that equation (2) does not change under the above replacement. The coefficients in both the dAKP and dBKP equation can be arbitrary nonzero numbers if we do not require \( \tau = 1 \) is a solution. In fact, all the coefficients \( z_i \) of the following dAKP equation

\[ z_1\pi + z_2\pi + z_3\pi + z_4\pi = 0, \quad \text{(5)} \]

can be gauged to be 1 by \( \tau \rightarrow \tau' \equiv \tau^{-m} z_1^{-m} z_2^{-m} z_3^{-m} \tau \) (cf. [16, 17]), and for the dBKP equation

\[ z_1\pi + z_2\pi + z_3\pi + z_4\pi = 0, \quad \text{(6)} \]

the transformation is (cf. [18])

\[ \tau \rightarrow \left( \frac{z_2 z_3}{z_1 z_4} \right)^{\frac{a}{b}} \left( \frac{z_1 z_3}{z_2 z_4} \right)^{\frac{b}{c}} \left( \frac{z_2 z_4}{z_1 z_3} \right)^{\frac{c}{a}} \tau'. \quad \text{(7)} \]

Equation (1) originated from Hirota’s discrete analogue of the generalized Toda equation (DAGTE) [9] that was parameterised later by Miwa [12] for the sake of expression of \( N \)-soliton solutions. It is also known as the discrete KP equation, the Hirota equation, or the Hirota–Miwa equation. Note that the DAGTE and the dAKP equation are equivalent in the sense that there exist a set of parameter transformations to transform them to each other [11]. Equation (2) was first given by Miwa [12] and now bears his name. It also appears as a nonlinear superposition formula of the (2 + 1) dimensional sine-Gordon system [18]. Both equations have Lax triads [16–18], and both equations are 4D consistent [1, 2].

Both the dAKP and dBKP equations have \( N \)-soliton solutions, which are possible to be written out from those of the continuous AKP and BKP equation (cf. [5]) by means of Miwa’s transformation [12]. Let us present these solutions by the following uniform formula,

\[ \tau = \sum_{\mu = 0, 1} \exp \left[ \sum_{j = 1}^{N} \mu_j \eta_j + \sum_{1 \leq i < j}^{N} \mu_i \mu_j \eta_{ij} \right], \quad \text{(8)} \]

where \( \epsilon^{\mu} = A_{ij} \), and the summation over \( \mu \) means to take all possible \( \mu_j = 0, 1 (j = 1, 2, \ldots, N) \). For the dAKP equation (1),

\[ \epsilon^a_i = \left( \frac{a - q_i}{a - p_i} \right)^{c - q_i} \left( \frac{b - q_i}{b - p_i} \right)^{c - q_i} \left( \frac{c - q_i}{c - p_i} \right)^{\eta_i^{(0)}}, \quad A_{ij} = \left( \frac{p_i - p_j}{q_i - q_j} \right) \left( \frac{q_i - q_j}{p_i - p_j} \right)^{\eta_i^{(0)}}. \quad \text{(9)} \]
while for the dBKP equation (2),

$$
\eta_i^{(0)} = \left\{ \begin{array}{l}
\frac{\prod_{j=1}^n (a - p_j)(a - q_j)}{\prod_{j=1}^n (a + p_j)(a + q_j)} \\
\frac{\prod_{j=1}^n (b - p_j)(b - q_j)}{\prod_{j=1}^n (b + p_j)(b + q_j)} \\
\frac{\prod_{j=1}^n (c - p_j)(c - q_j)}{\prod_{j=1}^n (c + p_j)(c + q_j)}
\end{array} \right\} \eta_i^{(0)},
$$

(10a)

$$
A_{ij} = \frac{(p_i - p_j)(p_i - q_j)(q_i - p_j)(q_i - q_j)}{(p_i + p_j)(p_i + q_j)(q_i + p_j)(q_i + q_j)},
$$

(10b)

where $\eta_i^{(0)} \in \mathbb{C}$. For the continuous AKP and BKP hierarchies, their $\tau$ functions can often be connected as [4]

$$
\tau_{\text{BKP}}^2 = \tau_{\text{AKP}}|_{\text{odd}}
$$

(11)

where the right-hand side means the AKP $\tau$ function with all the even-index coordinates removed. The relation (11) is thought to be true for the dAKP and dBKP under Miwa’s coordinates, but has strictly been shown only for special (mostly soliton type) solutions. The perfect square structure implies solutions in terms of Pfaffians for the (discrete) BKP hierarchy [6, 10, 23].

In this paper, we would like to investigate a different connection between the dAKP equation and dBKP equation. We will show that when $\tau_{\text{AKP}}$ has some special symmetries (see (16)) these two equations can share the same $\tau$ function. We will see that with these symmetries the dBKP equation can be expressed as a linear combination of the dAKP equation and its symmetric deformations. Such a connection can also be extended to 4 dimensional (4D) dAKP and dBKP equations, i.e. the higher order equations in the corresponding discrete hierarchies [4]. Various explicit forms of such $\tau$ functions will be given. In a sense these solutions of the dBKP equation could be considered to be ‘ reducible’ as they are also simultaneously solutions of the dAKP equation [4]. We will also investigate symmetric $\tau$ functions in Cauchy matrix form that are composed of Weierstrass $\sigma$ functions. As its most significant consequence, a dBKP equation with elliptic coefficients will be obtained, which is conjectured to be the canonical form for the elliptic solutions (including those which are not shared with the dAKP equation) of the dBKP equation.

The paper is organized as follows. In section 2 we discuss symmetric $\tau$ functions and connections between dAKP, dBKP, 4D dAKP and 4D dBKP equations. In section 3 various explicit forms of symmetric $\tau$ functions are given, including Hirota’s form, Gramian, Casoratian and polynomial. Then in section 4 we investigate symmetric $\tau$ functions composed of Weierstrass $\sigma$ function and present a dBKP equation with elliptic coefficients. Finally, conclusions are given in section 5.

2. Discrete AKP and BKP

Let $f(n_1, n_2, \ldots)$ be a function $f : \mathbb{Z}^+ \rightarrow \mathbb{C}$, and $(a_1, a_2, \ldots)$ corresponding spacing parameters associated with each lattice variable $(n_1, n_2, \ldots)$. Define shift operator $E_{n_i}$ by

$$
E_{n_i}f(n_1, n_2, \ldots) = f(n_1, \ldots, n_{i-1}, n_i + 1, n_i, n_{i+1}, \ldots).
$$

4 These equations are not really four-dimensional, as their integrability only holds modulo the lower equations in the hierarchy.

5 This is reminiscent of the reducible, i.e. special, solutions of the Painlevé equations which hold for special parameter values of those equations, for which also simultaneously a lower order equation is valid and which can be expressed in terms of classical special functions.
For convenience, we denote \((n_1, n_2, n_3, n_4) = (n, m, l, h)\), \((a_1, a_2, a_3, a_4) = (a, b, c, d)\), and the shifts by
\[
\tilde{f} = f(n + 1, m, l, h), \quad \hat{f} = f(n, m + 1, l, h), \quad \check{f} = f(n, m, l + 1, h), \quad \bar{f} = f(n, m, l, h + 1).
\]
We also employ the following notations with spacing parameters when necessary,
\[
\tau(n, m, l) \doteq \tau((n, a), m, l) \doteq \tau(n, (m, b), l) \doteq \tau(n, m, (l, c)).
\]
The celebrated Sato theory [13, 20] introduces plane wave factors \(e^{i(t,k)}\) with a universal dispersion relation (here \(t = (t_1, t_2, \ldots)\))
\[
\xi(t, k) = \sum_{i=1}^{\infty} k^i t_i.
\]
Miwa introduced, for instance, for the dAKP equation, the discrete plane wave factors [12]
\[
\prod_{i=1}^{\infty} \left( \frac{1 - a_i p}{1 - a_i q} \right)^{t_i}
\]
which can be rewritten in a continuous exponential function form by \(e^{-i(t,p)+(t,q)}\), where
\[
x_j = \frac{1}{f} \sum_{i=1}^{\infty} n_i a_i^j
\]
and \(x = (x_1, x_2, \ldots)\) are usually referred to as Miwa’s coordinates. Discrete integrable systems can be investigated by means of Sato’s theory with Miwa’s coordinates.

2.1. Reflection symmetric \(\tau\) function, dAKP and dBKP

Suppose that \(\tau(n, m, l)\) has the following symmetries
\[
\tau((n, a), m, l) = \tau((-n, -a), m, l), \quad (16a)
\]
\[
\tau(n, (m, b), l) = \tau(n, (-m, -b), l), \quad (16b)
\]
\[
\tau(n, m, (l, c)) = \tau(n, m, (-l, -c)). \quad (16c)
\]
If \(\tau\) is a solution of the dAKP equation (1), then the above symmetries lead to the reflected dAKP equations, respectively,
\[
A_1 \doteq (b - c)\tilde{\tau} + (c + a)\hat{\tau} - (a + b)\check{\tau} = 0, \quad (17a)
\]
\[
A_2 \doteq (c - a)\tilde{\tau} + (a + b)\hat{\tau} - (b + c)\check{\tau} = 0, \quad (17b)
\]
\[
A_3 \doteq (a - b)\tilde{\tau} + (b + c)\hat{\tau} - (c + a)\check{\tau} = 0. \quad (17c)
\]
In fact, if \(\tau\) has symmetry (16a), it then follows from (1) that
\[
(-a - b)\hat{\tau} + (b - c)\check{\tau} + (c + a)\tilde{\tau} = 0.
\]
By an up shift in tilde direction we immediately get (17a)–(17c) can be derived in a similar way.

Then we present the following connection between the dAKP and dBKP equations.

**Theorem 1.** If \( \tau \) satisfies the dAKP equation (1) and has symmetries (16), then \( \tau \) satisfies the dBKP equation (2).

**Proof.** For the dAKP \( \tau \) function, when it has symmetries (16), \( \tau \) satisfies (1) and (17) simultaneously. Direct calculation gives rise to
\[
(c - a)(a - b) \times A_1 + (a - b)(b - c) \times A_2 + (b - c)(c - a) \times A_3 \\
+ (a^2 + b^2 + c^2 + 3ab + 3bc + 3ca) \times A = 3 \times B.
\] (18)

**Remark 1.** Among the dAKP equation (1) and the reflected dAKP equations (17), \( A, A_1, A_2, A_3 \) are not linearly independent. Apart from the relation
\[
A_1 + A_2 + A_3 = A,
\]
any element in \( \{A, A_1, A_2, A_3\} \) can be a linear combination of any two elements of the same set. For example,
\[
A = \frac{a - c}{a + b} A_1 + \frac{b - c}{a + b} A_2, \quad A_3 = \frac{b + c}{a + b} A_1 - \frac{a + c}{a + b} A_2.
\]
This indicates that there are alternative expressions of (18) in terms of only two elements of \( \{A, A_1, A_2, A_3\} \). For example, we have
\[
B = (a + b)(a + c)A - (a - b)(a - c)A_1 = (a - c)(b + c)A_1 - (b - c)(a + c)A_2,
\] (19)
which is simpler than (18).

**Remark 2.** Note that the symmetries can be extended to
\[
\tau((n, a), m, l) = \gamma_1 A_1^n B_1^m C_1^l \tau((−n, −a), m, l), \quad (20a)
\]
\[
\tau(n, (m, b), l) = \gamma_2 A_2^n B_2^m C_2^l \tau(n, (−m, −b), l), \quad (20b)
\]
\[
\tau(n, (m, (l, c))) = \gamma_3 A_3^n B_3^m C_3^l \tau(n, (−l, −c)), \quad (20c)
\]
where \( A_i, B_i, C_i, \gamma_i \) are nonzero constants. Due to the gauge property of discrete bilinear equations (e.g. [8]), theorem 1 and (17) are still valid if replacing (16) with (20).

### 2.2. 4D dAKP

The 4D dAKP equation is given in [19] via a compact form
\[
\begin{array}{cccc}
  a^2 & a & 1 & \tilde{\tau}^a \\
  b^2 & b & 1 & \tilde{\tau}^b \\
  c^2 & c & 1 & \tilde{\tau}^c \\
  d^2 & d & 1 & \tilde{\tau}^d \\
\end{array}
= 0,
\] (21)
which has an explicit expression
\[(b - c)(c - d)(b - d)\hat{\tilde{\tau}} - (a - c)(c - d)(a - d)\tilde{\tau} + (a - b)(b - d)(a - d)\tau\tilde{\hat{\tau}} = 0.\] (22)

The dAKP equation (1) is 4D consistent [2]. We note that the above 4D dAKP equation is a result of 4D consistency of (1). In fact, embedding eight copies of the dAKP equations on a hypercube (see figure 1) and then calculating a triply shifted \(\tau\) with proper initial points, (e.g. calculating \(\hat{\tilde{\tau}}\) with initials \(\tilde{\tau}\), \(\hat{\tau}\), \(\tilde{\tau}\), \(\hat{\tilde{\tau}}\), \(\hat{\hat{\tau}}\), \(\tilde{\hat{\tau}}\)), one gets the 4D dAKP equation (22). In addition to (22), the dAKP equation defined on three elementary cubes can yield another 4D lattice equation (cf equation (29) in [2])
\[A_0 = (a - b)(c - d)\hat{\tilde{\tau}} - (a - c)(b - d)\tilde{\tau} + (a - d)(b - c)\tau\hat{\hat{\tau}} = 0.\] (23)

With regard to solutions, by virtue of 4D consistency, if we consistently extend the dAKP plane wave factor in (9) to the 4th dimension, then the resulted \(\tau\) function will be a solution to the 4D equations (22) and (23) as well.

2.3. 4D dBKP

The 4D dBKP equation is (see equation (2.4) in [23])
\[(a - b)(a - c)(a - d)(b - c)(b - d)(c - d)\hat{\tilde{\tau}} - (a - b)(a + c)(a + d)(b + c)(b + d)(c - d)\tilde{\tau}\hat{\hat{\tau}} + (a + b)(a - c)(a + d)(b + c)(b - d)(c + d)\tau\hat{\hat{\tau}} - (a + b)(a + c)(a - d)(b - c)(b + d)(c + d)\tilde{\tau}\hat{\tilde{\tau}} = 0.\] (24)

There are at least three ways by which the above equation is connected with known lattice equations. First, this equation is a result of the 4D consistency of the dBKP equation (2) [1].
Second, a more precise relation between the 4D dBKP and 3D dBKP can be given. Denoting the 3D dBKP equation (2) by dBKP\((n, m, l) = 0\) and the 4D dBKP equation (24) by 4DbKP\((n, m, l, h) = 0\), then we have (cf [24])

\[
- \hat{\tau} \times 4\text{d}bKP(n, m, l, h)(a + b)(a + c)(a - d)\hat{\tau} \times \text{dBKP}(h, m, l)
+ (a + b)(b + c)(b - d)\hat{\tau} \times \text{dBKP}(n, h, l)
+ (a + c)(b + c)(c - d)\hat{\tau} \times \text{dBKP}(n, m, h)
+ (a - d)(b - d)(c - d)\tau \times E_3\text{dBKP}(n, m, l).
\]

The third way is the connection with the 4D dAKP equation (22) when \(\tau\) allows symmetries (16) and

\[
\tau(n, m, l, (h, d)) = \tau(n, m, l, (-h, -d)). \tag{25}
\]

With these symmetries the 4D dAKP equation (22) yields

\[
\begin{align*}
A_1 \doteq (b - c)(c - d)(b - d)\hat{\tau} \times (a + c)(c - d)(a + d)\hat{\tau} \\
+ (a + b)(b + c)(b - d)(a + d)\tilde{\tau} - (a + b)(b - c)(a + c)\hat{\tau} = 0, \\
A_2 \doteq (a - c)(c - d)(a - d)\hat{\tau} \times (b + c)(c - d)(d + b)\hat{\tau} \\
+ (a + b)(b + d)(a - d)\hat{\tau} - (a + b)(b + c)(a - c)\hat{\tau} = 0, \\
A_3 \doteq (a - b)(b - d)(a - d)\hat{\tau} + (a + c)(c + d)(a - d)\tilde{\tau} \\
- (b + c)(c + d)(b - d)\tilde{\tau} - (a - b)(b + c)(a + c)\hat{\tau} = 0, \\
A_4 \doteq (a - b)(b - c)(a - c)\hat{\tau} + (a - c)(c + d)(d + a)\tilde{\tau} \\
- (a - b)(b + d)(d + a)\tilde{\tau} - (b - c)(c + d)(d + b)\hat{\tau} = 0.
\end{align*}
\]

Together with (23), on can find

\[
4 \times 4\text{d}bKP(n, m, l, h) = (a - b)(a - c)(a - d)A_1 + (a - b)(b - c)(b - d)A_2 \\
+ (a - c)(b - c)(c - d)A_3 \\
+ (a - d)(b - d)(c - d)A_4 + \left[a^2 - b^2 + c^2 - d^2\right]^2 \\
- 4(a + b)(b + c)(a + d)(c + d)A_0.
\]

Then, for solutions of the 4D dBKP equation (24), we have the following.

**Theorem 2.** Once we have a dAKP \(\tau\) function, we consistently extend its plane wave factor to the 4th dimension and impose symmetries (16) and (25). Then the \(\tau\) function is a solution to the 4D dBKP equation (24).
3. \(\tau\) functions with symmetries

We construct \(\tau\) function that possesses symmetries (16) or (20). Obviously, the \(\tau\) function in Hirota’s form (8) with (9) \(|q_i = -p_i|\), i.e.

\[
\eta_i = \left(\frac{a + p_i}{a - p_i}\right)^n \left(\frac{b + p_i}{b - p_i}\right)^m \left(\frac{c + p_i}{c - p_i}\right), \quad A_{ij} = \frac{(p_i - p_j)^2}{(p_i + p_j)^2}, \quad (26)
\]

agrees with the symmetries (16). Such a \(\tau\) function provides soliton solutions for the dAKP equation (1) as well as for the dBKP equation (2) in light of Theorem 1. It is remarkable that (26) cannot be obtained from the dBKP plane wave factor and phase factor (10) by imposing constraints on \((p_j, q_j)\). In the following we will go through more forms of \(\tau\) functions with the desired symmetries.

3.1. Gramian form via Cauchy matrix approach

In order to derive a more general \(\tau\) function, we construct it by means of Cauchy matrix approach (cf [7, 15, 28]). Consider the Sylvester equation

\[
KM + K = rc^T, \quad (27)
\]

where \(K\) is a given \(N \times N\) constant matrix and \(-K\) do not share eigenvalues, \(M \in \mathbb{C}_{N \times N}\), \(r = (r_1, r_2, \ldots, r_N)^T\) and \(r_i\) are functions \(r_i : \mathbb{Z}^\infty \rightarrow \mathbb{C}\), and \(c = (c_1, c_2, \ldots, c_N)^T\) with \(c_i \in \mathbb{C}\). Dispersion relations are introduced through

\[
\tilde{r} = (a - K)^{-1}(a + K)r, \quad (28a)
\]

\[
\hat{r} = (b - K)^{-1}(b + K)r, \quad (28b)
\]

\[
\tilde{r} = (c - K)^{-1}(c + K)r. \quad (28c)
\]

Since \(K\) and \(-K\) do not have common eigenvalues, \(M\) is uniquely determined by (27) with give \((K, r, c)\) [22]. Here for the spacing parameters \(a, b, c\) we skip the unit matrix \(I\) without any confusion in notations. Then, it can be proved that \(M\) obeys the following shift evolutions [28]

\[
\tilde{M}(a + K) - (a + K)M = \tilde{r}c^T, \quad (29a)
\]

\[
(a - K)\hat{M} - M(a - K) = rc^T, \quad (29b)
\]

and the parallel relations for \((m, b)\) and \((l, c)\). Then we introduce scalar functions

\[
S^{(i, j)} = c^T K^l (I + M)^{-1} K^j r, \quad (30a)
\]

\[
S^{(\alpha, j)} = c^T K^l (I + M)^{-1} (\alpha + K)^{-1} r, \quad (30b)
\]

\[
S^{(i, \beta)} = c^T (\beta + K)^{-1} (I + M)^{-1} K^i r, \quad (30c)
\]

with \(i, j \in \mathbb{Z}\), \(\alpha, \beta \in \mathbb{C}\), and define \(\tau\) function as

\[
\tau = |I + M|. \quad (31)
\]
One can derive evolutions of these functions. $S = (S^{(i,j)})_{i,j=\infty}^{\infty}$ is a symmetric matrix [28], i.e. $S^{(i,j)} = S^{(j,i)}$. Evolutions for $S^{(i,j)}$ can be described as (cf [15, 28])

$$\begin{align*}
as_S^{(i,j)} - \tilde{S}^{(i,j)} &= aS^{(i,j)} + S^{(i,j+1)} - S^{(0,0)}\tilde{S}^{(0,0)}, \quad (32a) \\
as_S^{(i,j)} + \tilde{S}^{(i,j+1)} &= a\tilde{S}^{(i,j)} + \tilde{S}^{(i,j+1)} - S^{(0,0)}S^{(0,0)} , \quad (32b)
\end{align*}$$

and parallel relations for $(m, b)$ and $(l, c)$. One more symmetric relation is $S^{(\alpha, j)} = S^{(j, \alpha)}$ due to $S^{(i,j)} = S^{(j,i)}$ and the expansion

$$S^{(\alpha, j)} = \sum_{i=0}^{\infty} (-1)^i \frac{\alpha}{\alpha+1} S^{(i,j)}, \quad S^{(j, \alpha)} = \sum_{i=0}^{\infty} (-1)^i \frac{\alpha}{\alpha+1} S^{(j,i)}.$$

With the above expansion and (32) one can obtain evolutions of $S^{(\alpha, j)}$ as

$$\begin{align*}
aS^{(\alpha, j)} - \tilde{S}^{(\alpha, j)} &= (a - \alpha)S^{(\alpha, j)} + S^{(0,0)}(1 - \tilde{S}^{(\alpha, 0)}), \quad (33a) \\
bS^{(\alpha, j)} - \tilde{S}^{(\alpha, j)} &= (b - \alpha)S^{(\alpha, j)} + S^{(0,0)}(1 - \tilde{S}^{(\alpha, 0)}), \quad (33b) \\
cS^{(\alpha, j)} - \tilde{S}^{(\alpha, j)} &= (c - \alpha)S^{(\alpha, j)} + S^{(0,0)}(1 - \tilde{S}^{(\alpha, 0)}), \quad (33c)
\end{align*}$$

Next, let us derive some relations on $\tau$ and the functions in (30) (cf [7]).

**Lemma 1.** $\tau$ function (31) obeys evolutions

$$\begin{align*}
\tilde{\tau}/\tau &= 1 - S^{(0, -a)}, \quad (34a) \\
\tau/\tilde{\tau} &= 1 - \tilde{S}^{(0, a)}, \quad (34b)
\end{align*}$$

and the parallel relations for $(m, b)$ and $(l, c)$.

**Proof.** First,

$$|a - K|\tilde{\tau} = |a - K||I + \tilde{M}| = |a - K + M(a - K) + rc^T|,$$

i.e.,

$$\tilde{\tau} = |I + M + rc^T(a - K)^{-1}| = |I + M||I + rc^T(a - K)^{-1}(I + M)^{-1}|.$$

Then, by means of Weinstein–Aronszajn identity $|I + rc^T| = 1 + c^Tr$, one has

$$\tilde{\tau}/\tau = 1 - c^T(K - a)^{-1}(I + M)^{-1}r = 1 - S^{(0, -a)}.$$

(34b) can be proved as the following.

$$|a + K|\tau = |a + K||I + M| = |a + K + \tilde{M}(a + K) - \tilde{rc}^T|,$$

and

$$\tau = |I + \tilde{M} - \tilde{rc}^T(a + K)^{-1}| = |I + \tilde{M}||I - \tilde{rc}^T(a + K)^{-1}(I + \tilde{M})^{-1}|.$$

It then follows from the Weinstein–Aronszajn identity that one gets (34b).
Lemma 2. Setting $u = S^{(0,0)}$, we have the following relations

$$
(a - b + \tilde{a} - \tilde{u}) = (a - b) \frac{\tilde{\tau}}{\tilde{\tau}}, \quad (35a)
$$

$$
(b - c + \tilde{b} - \tilde{u}) = (b - c) \frac{\tilde{\tau}}{\tilde{\tau}}, \quad (35b)
$$

$$
(c - a + \tilde{c} - \tilde{u}) = (c - a) \frac{\tilde{\tau}}{\tilde{\tau}}. \quad (35c)
$$

Proof. The proof has been given in [15] for the case $K$ is diagonal. Here let us extract out main steps and extend them to the case of arbitrary $K$.

Considering the evolutions of $S(\alpha, j)$ given in (33a) and (33b) where we take $\alpha = a, j = 0$, we get

$$
a \tilde{S}(a, 0) - \tilde{S}(a, 1) = u(1 - \tilde{S}(a, 0)), \quad (36a)
$$

$$
b \tilde{S}(a, 0) - \tilde{S}(a, 1) = (b - a) S(a, 0) + u(1 - \tilde{S}(a, 0)). \quad (36b)
$$

Eliminating $S(a, 1)$ from the above gives rise to

$$
(a - b + \tilde{a} - \tilde{u})(1 - \tilde{S}(a, 0)) - (a - b)(1 - \tilde{S}(a, 0)) = 0, \quad (37)
$$

which indicates the relation (35a) using (34b). (35b) and (35c) can be obtained in a similar way.

Thus, combining the three equations in (35) together, we get the dAKP equation.

Theorem 3. The $\tau$ function defined in (31) satisfies the dAKP equation (1).

Solution $M$ to the Sylvester equation (27) and $r$ to the dispersion relation (28) can be written out in terms of the canonical forms of $K$. For a given $K$, the dispersion relation (28) indicates the symmetry for $r$: $r((n_i, a_i)) = r((-n_i, -a_i))$, so is for $M$, i.e. $M((n_i, a_i)) = M((-n_i, -a_i))$, and so is for $\tau$, i.e. $\tau((n_i, a_i)) = \tau((-n_i, -a_i))$.

Canonical form of $K$ is composed of a diagonal matrix and different Jordan blocks. When $K$ is a diagonal matrix $K = \text{diag}\{p_1, p_2, \ldots, p_N\}$, $r$ consists of $r_i = \eta_i$ where $\eta_i$ is given in (26), and $M = (m_{ij})_{N \times N}$ consists of

$$
m_{ij} = \frac{r_i c_j}{p_i + p_j}. \quad (38)
$$

Then, $\tau = |I + M|$ is a Gramian which is a special case of the solution obtained in [19]. When $K$ is a Jordan block and a more general form, one can refer to section 4 of [28] for explicit forms of $r$ and $M$.

3.2. Casoratian solutions

The deformed dAKP equation (17b) also appeared as a member in the bilinear forms of H3 equation in the Adler-Bobenko-Suris (ABS) list [1], (see equation (5.20a) in [8]). It allows a Casoratian solution [8]

$$
\tau(\psi) = |\psi(n, m, l), \psi(n, m, l + 1), \psi(n, m, l + 2), \ldots, \psi(n, m, l + N - 1)|, \quad (39a)
$$
where $\psi = (\psi_1, \psi_2, \ldots, \psi_N)^T$ and
$$
\psi_i = \gamma^+_i (a + p_i)^m (b + p_i)^n (c + p_i)^l + \gamma^-_i (a - p_i)^m (b - p_i)^n (c - p_i)^l, \quad \gamma^\pm_i \in \mathbb{C}.
$$

(39b)

At the first glance, $\tau(\psi)$ does not have symmetries (16). However, by means of the gauge property of Hirota’s discrete bilinear equations, $\tau(\psi)$ does satisfy the dAKP and dBKP equations simultaneously.

**Theorem 4.** The $\tau$ function $\tau(\psi)$ defined in (39) is a solution of the dAKP equation (1) as well as the dBKP equation (2).

**Proof.** In addition to $\psi$, we introduce $N$th order column vectors $\varphi$, $\omega$ and $\theta$ that are composed of, respectively, (cf [8])

$$
\varphi_i = \gamma^+_i (a + p_i)^m (b + p_i)^n (c + p_i)^l + \gamma^-_i (a + p_i)^m (b - p_i)^n (c - p_i)^l, \quad (40a)
$$

$$
\omega_i = \gamma^+_i (a + p_i)^m (b + p_i)^n (c + p_i)^l + \gamma^-_i (a - p_i)^m (b + p_i)^n (c - p_i)^l, \quad (40b)
$$

$$
\theta_i = \gamma^+_i (a + p_i)^m (b + p_i)^n (c - p_i)^l + \gamma^-_i (a - p_i)^m (b - p_i)^n (c + p_i)^l. \quad (40c)
$$

One can prove that (cf [8])

$$
\tau(\psi((n, a), (m, b), l)) = A^n \tau(\varphi((n, a), m, l))
= (-1)^N c A^n \tau(\psi((n, -a), m, l))
= B^n \tau(\omega(n, (m, b), l))
= (-1)^N c B^n \tau(\psi(n, (-m, -b), l)),
$$

where $A = \prod_{i=1}^{N} (a^2 - p_i^2)$ and $B = \prod_{i=1}^{N} (b^2 - p_i^2)$. This means that $\tau(\psi)$ satisfies the extended symmetries (20) in $n$ and $m$-direction. Meanwhile, note that due to the relation $\psi - \psi = (a - c)\psi$, the $\tau$ function (39a) can be equivalently constructed in terms of shifts of $n$, i.e.

$$
\tau(\psi) = |\psi(n, m, l), \psi(n + 1, m, l), \psi(n + 2, m, l), \ldots, \psi(n + N - 1, m, l)|, \quad (41)
$$

(see equation (2.24) in [8]). With this notation,

$$
\tau(\psi(n, m, (l, c))) = C_l \tau(\theta(n, m, (l, c))) = (-1)^N c C_l \tau(\psi(n, m, (-l, -c)),$$

where $C = \prod_{i=1}^{N} (c^2 - p_i^2)$. This gives the extended symmetries (20c). Thus, due to the gauge property of Hirota’s discrete bilinear equations, (39) allows symmetries (20) and consequently provides a solution for both the dAKP and dBKP equations.

Multiple pole solutions of the deformed dAKP equation (17b) is given by $\psi(\psi)$ in the Casoratian form (39a), but where

$$
\psi_1 = (39b)|_{j=1}, \quad \psi_j = \frac{1}{(j - 1)!} \frac{\partial^{j-1}}{\partial p_1} \psi_1, \quad (j = 2, 3, \ldots). \quad (42)
$$

This can be found in theorem 1 in [21]. We claim that $\tau(\psi)$ with (42) satisfies the extended symmetries (20) and then it solves the dAKP and the dBKP as well. To elaborate this, we
introduce lower triangular Toeplitz matrix (LTTM)

\[ T = \begin{pmatrix}
  t_0 & 0 & \ldots & 0 & 0 \\
  t_1 & t_0 & \ldots & 0 & 0 \\
  \vdots & \vdots & \ddots & \vdots & \vdots \\
  t_{N-2} & t_{N-3} & \ldots & t_0 & 0 \\
  t_{N-1} & t_{N-2} & \ldots & t_1 & t_0
\end{pmatrix} \]

(43)

and note that such a matrix can be generated by some function \( f(p) \) via taking

\[ t_j = \frac{1}{j!} \partial^j f(p), \quad j = 0, 1, \ldots \]  

(44)

For convenience, by \( T[f(p)] \) we denote an LTTM generated by the function \( f(p) \) via (44). We also introduce new auxiliary vectors \( \varphi, \omega \) and \( \theta \) by

\[ \varphi_1 = (40a)|_{j=1}, \quad \varphi_j = \frac{1}{(j-1)!} \partial^{j-1}_p \varphi_1, \]

(45a)

\[ \omega_1 = (40b)|_{j=1}, \quad \varphi_j = \frac{1}{(j-1)!} \partial^{j-1}_p \omega_1, \]

(45b)

\[ \theta_1 = (40a)|_{j=1}, \quad \theta_j = \frac{1}{(j-1)!} \partial^{j-1}_p \theta_1, \]

(45c)

for \( j = 2, 3, \ldots \). Note that these vectors are connected to \( \psi \) composed of (42) by

\[ \psi = T[a^2 - p_1^3] \varphi = T[b^2 - p_1^3] \omega = T[c^2 - p_1^3] \theta. \]  

(46)

Then we have

\[ \tau(\psi((n, a), (m, b), (l, c))) \]

\[ = T[a^2 - p_1^3] \tau(\varphi((n, a), (m, l))) = (p_2^2 - a^2)^r \tau(\psi((-n, -a), (m, l))) \]

\[ = T[b^2 - p_1^3] \tau(\omega((n, (m, b), l))) = (p_2^2 - b^2)^m \tau(\psi((n, (-m, -b), l))) \]

\[ = T[c^2 - p_1^3] \tau(\theta((n, m, (l, c))) = (p_2^2 - c^2)^l \tau(\psi((n, m, (-l, -c))), \]

which are in the form of the extended symmetries (20).

Let us sum up the above discussion by the following theorem.

**Theorem 5.** The function \( \tau(\psi) \) composed of (42) provides a multiple pole solution to the dAKP equation (1) as well as the dBKP equation (2).

### 3.3. Polynomial solutions

The dAKP equation has polynomial solutions (cf [16]). Explicit form of these solutions can be described as the following.

**Lemma 3.** [29] Let

\[ \psi^+_0 = \varphi_0(1 + p/a)^r(1 + p/b)^m(1 + p/c)^l(1 + p)^r. \]  

(47)
where

\[ \varrho_0 = \frac{1}{2} e^{-\sum_{j=1}^{\infty} \frac{(-p^j)}{j} \gamma_j}, \quad \gamma_j \in \mathbb{C}. \]

Then,

\[ \psi_0^+ = \frac{1}{2} \sum_{j=0}^{\infty} \phi_j p^j, \quad \left( \phi_j = \frac{2}{j!} \frac{\partial^j \psi_0^+}{\partial p^j} \bigg|_{p=0} \right) \]

\[ = \frac{1}{2} \exp \left[ -\sum_{j=1}^{\infty} \frac{(-p)^j}{j} \tilde{x}_j \right], \]

where

\[ \tilde{x}_j = x_j + s, \quad x_j = na^{-j} + mb^{-j} + lc^{-j} + \gamma_j. \]  \hfill (48)

\[ \phi_j = \phi_j(n, m, l, s) \text{ can be expressed in terms of } x_j \text{ by} \]

\[ \phi_j = (-1)^j \sum_{\|\mu\|=j} (-1)^{|\mu|} \tilde{x}^\mu_\mu \]  \hfill (49)

where

\[ \mu = (\mu_1, \mu_2, \ldots), \quad \mu_j \in \{0, 1, 2, \ldots\}, \quad \|\mu\| = \sum_{j=1}^{\infty} j \mu_j, \]

\[ |\mu| = \sum_{j=1}^{\infty} \mu_j, \quad \mu! = \mu_1! \cdot \mu_2! \cdot \ldots, \quad \tilde{x}^\mu = \left( \frac{\tilde{x}_1}{1!} \right)^{\mu_1} \left( \frac{\tilde{x}_2}{2!} \right)^{\mu_2} \cdot \ldots \]

The first few \( \phi_j \) are

\[ \phi_0 = 1, \quad \phi_1 = \tilde{x}_1, \quad \phi_2 = \frac{1}{2} (\tilde{x}_1^2 - \tilde{x}_2), \quad \phi_3 = \frac{1}{6} (\tilde{x}_1^3 - 3\tilde{x}_1\tilde{x}_2 + 2\tilde{x}_3), \]

\[ \phi_4 = \frac{1}{24} (\tilde{x}_1^4 - 6\tilde{x}_1^2\tilde{x}_2 + 8\tilde{x}_1\tilde{x}_3 + 3\tilde{x}_2^2 - 6\tilde{x}_4). \]

Define

\[ \phi = (\phi_1, \phi_3, \phi_5, \ldots, \phi_{2N-1})^T. \]  \hfill (50)

The Casoratian

\[ \tau_N(\phi) = |\phi(n, m, l, 0), \phi(n, m, l, 1), \phi(n, m, l, 2), \ldots, \phi(n, m, l, N-1)| \]

is a solution of the deformed dAKP equation \( (17c) \) (i.e. equation \( (3.15) \) in [29]).

Note that \( \tau_N(\phi) \) satisfies the superposition formula [27]

\[ \tau_{N-1}(E_n \tau_{N+1}) - \tau_{N+1}(E_n \tau_{N-1}) = \frac{1}{a_i} \tau_N(E_n \tau_N), \]

and provides a discrete analogue of the remarkable Burchall–Chaundy polynomials (cf [25]).
Let us look at symmetries of $\tau_N(\phi)$. The first three are

$$
\tau_1(\phi) = x_1, \quad \tau_2(\phi) = \frac{x_1^3 - x_3}{3}, \quad \tau_3(\phi) = \frac{1}{45}x_1^6 - \frac{1}{9}x_1^3x_3 + \frac{1}{5}x_1x_5 - \frac{1}{9}x_3^2,
$$

which only depend on $\{x_{2i+1}\}$. For general $N$, it has been proved that (in appendix C of [27])

**Lemma 4.** $\tau_N(\phi)$ depends only on $\{x_1, x_3, \ldots, x_{2N-1}\}$.

Thus, from the definition (48) of $x_j$, we immediately find that $\tau_N(\phi)$ has symmetries (16). This then leads to polynomial solutions of the dBKP equation.

**Theorem 6.** The $\tau$ function $\tau(\phi)$ defined by (51) provides polynomial solutions for the dAKP equation (1) as well as the dBKP equation (2).

### 4. Elliptic case

#### 4.1. dAKP

Equation (2.51) in [26] is a version of dAKP equation ready for elliptic solitons. It is written as

$$
E_0 \sigma(c)\sigma(a-b)\tau + \sigma(a)\sigma(b-c)\tilde{\tau} + \sigma(b)\sigma(c-a)\tilde{\tau} = 0,
$$

(55)

where

$$
\Phi_a(b) = \Phi_a^b = \frac{\sigma(a+b)}{\sigma(a)\sigma(b)}.
$$

(54)

Here and below, $\sigma(z)$, $\zeta(z)$ and $\wp(z)$ are the Weierstrass functions. Equation (53) can also be written as

$$
\sigma(c)\sigma(a-b)\bar{\tau} + \sigma(a)\sigma(b-c)\tilde{\bar{\tau}} + \sigma(b)\sigma(c-a)\tilde{\tau} = 0.
$$

(55)

Note that this is similar to (3), not to (1).

The following $\tau$ function is given as an elliptic soliton solution of the dAKP equation (53), [26]

$$
\tau = \sigma(\xi)|I + \mathcal{M}|
$$

(56)

where

$$
\xi = an + bm + cl + \xi_0, \quad \xi_0 \in \mathbb{C},
$$

(57)

$$
\mathcal{M} = (\mathcal{M}_{ij})_{N \times N}, \quad \mathcal{M}_{ij} = \rho_i\mathcal{M}_{ij}^0\nu_j,
$$

(58a)

$$
\rho_i = (\Phi_a(-\kappa_i))^{m}(\Phi_a(-\kappa_i))^{m} e^{\xi(\xi_0+\kappa_i)},
$$

(58b)

$$
\nu_j = (\Phi_a(\kappa_j'))^{-m}(\Phi_a(\kappa_j'))^{-m} e^{\xi(\xi_0+\kappa_j')},
$$

(58c)

$$
\mathcal{M}_{ij}^0 = \Phi_a(\kappa_i + \kappa_j') e^{-\xi(\xi_0+\kappa_i)},
$$

(58d)

and $\kappa_i, \kappa_j' \in \mathbb{C}$ for $i, j = 1, 2, \ldots, N$. 

14
4.2. Symmetries of the $\tau$ function

To get a $\tau$ function that allows symmetries (16), we take

$$\kappa'_j = \kappa_j, \quad p^0(\kappa_j) = \nu^0(\kappa_j), \quad (j = 1, 2, \ldots, N). \quad (59)$$

Obviously, $\xi(-n, -a) = \xi(n, a)$. In addition, with (59) we have

$$\mathcal{M}_{ij} = S_i \Phi_{\xi}(\kappa_i + \kappa_j) T_j, \quad (60a)$$

where

$$S_i = (\Phi_a(-\kappa_i))^{-n}(\Phi_b(-\kappa_i))p^0(\kappa_i), \quad (i = 1, 2, \ldots, N), \quad (60b)$$

$$T_j = (\Phi_a(\kappa_j))^n(\Phi_b(\kappa_j))^{-n}(\Phi_c(\kappa_j))^{-l}p^0(\kappa_j), \quad (j = 1, 2, \ldots, N). \quad (60c)$$

Noticing that

$$S_i(-n, -a) = A_i^n S_i(n, a), \quad T_j(-n, -a) = A^{-n}_i T_j(n, a),$$

where

$$A_i = -\frac{\sigma^2(a)\sigma^2(\kappa_i)}{\sigma(\kappa_i + a)\sigma(\kappa_i - a)} = \frac{1}{\varphi(\kappa_i) - \varphi(a)},$$

we then have

$$\tau(-n, -a) = \sigma(\xi)[I + \mathcal{M}](-n, -a)$$

$$= \sigma(\xi) \text{Det} [\text{Diag}(A_1^n, A_2^n, \ldots, A_N^n)]$$

$$\times (I + \mathcal{M})_{(n, a)} \text{Diag}(A_1^{-n}, A_2^{-n}, \ldots, A_N^{-n})$$

$$= \sigma(\xi)[I + \mathcal{M}]_{(n, a)} = \tau(n, a).$$

Since the symmetries w.r.t. $m$ and $l$ can be proved similarly, one can conclude that

**Lemma 5.** The function $\tau = \sigma(\xi)[I + \mathcal{M}]$, where $\mathcal{M}_{ij}$ are defined in (60), allows symmetries (16).

4.3. dBKP

Now that the dAKP $\tau$ function defined in lemma 5 allows symmetries (16), as the counterparts of (17), from (53) we have deformations

$$\mathcal{E}_1 \equiv \Phi_{b}^{\mu} \widehat{T}_\tau + \Phi_{b}^{\nu} \widehat{T}_\tau - \Phi_{b}^{\rho} \widehat{T}_\tau = 0, \quad (61a)$$

$$\mathcal{E}_2 \equiv \Phi_{a}^{-\mu} \widehat{T}_\tau + \Phi_{a}^{-\nu} \widehat{T}_\tau - \Phi_{a}^{-\rho} \widehat{T}_\tau = 0, \quad (61b)$$

$$\mathcal{E}_3 \equiv \Phi_{a}^{-\mu} \widehat{T}_\tau + \Phi_{a}^{-\nu} \widehat{T}_\tau - \Phi_{a}^{-\rho} \widehat{T}_\tau = 0, \quad (61c)$$

where we have made use of $\Phi_{b}^{\mu} = \Phi_{b}^{\nu} = -\Phi_{b}^{-\mu}$. To derive a dBKP equation with elliptic coefficients, multiplying $\Phi_{a}^{-\mu} \Phi_{a}^{-\nu} \Phi_{a}^{-\rho}, \Phi_{b}^{-\mu} \Phi_{b}^{-\nu} \Phi_{b}^{-\rho}, \Phi_{c}^{-\mu} \Phi_{c}^{-\nu} \Phi_{c}^{-\rho}$ to the three equations in (61), respectively, and summing them together, we get
Elliptic solutions of this dBKP equation are given by

\[
f = A^{-\frac{1}{2}} B^{-\frac{1}{2}} C^{-\frac{1}{2}} \sigma (\xi) |I + M|,
\]

where \(M_{ij}\) are defined in (60) and \(A, B, C\) are given in (67b).
Remark 3. $E_i$ ($i = 0, 1, 2, 3$) can be expressed as linear combinations of any two elements of \{E_0, E_1, E_2, E_3\}, for example,
\[
\Phi^b_a E_0 = -\Phi^a_c E_1 + \Phi^c_e E_2, \quad \Phi^b_d E_3 = -\Phi^d_e E_1 - \Phi^e_d E_2. \tag{70}
\]
This also means there are alternative expressions of (66), e.g.
\[
\Phi^b_a F = -\Phi^a_c \psi(b) E_1 + \Phi^c_e \psi(a) E_2.
\]
\[
F = \phi(a) E_0 + \Phi^a_b \Phi^b_a E_0.
\]
Note that to obtain (70) we need to make use of a special case ($v = 0$) of the well-known identity
\[
\sigma(x + y) \sigma(x - y) \sigma(u + v) \sigma(u - v) = \sigma(x + u) \sigma(x - u) \sigma(y + v) \sigma(y - v) - \sigma(x + v) \sigma(x - v) \sigma(y + u) \sigma(y - u). \tag{71}
\]
Finally, let us back to the equation dAKP (55) and dBKP (65). Both of them have the simplest solution $\tau = \sigma(\xi)$ where $\xi$ is given in (13). In this case (55) is related to the identity (71) by (cf [14, 26])
\[
x = \frac{1}{2} (a - b + c), \quad y = \frac{1}{2} (c - a + b), \quad u = \xi + \frac{1}{2} (a + b + c), \quad v = \frac{1}{2} (a + b - c),
\]
or, equivalently,
\[
a = x + v, \quad b = y + v, \quad c = x + y, \quad \xi = u - x - y - v. \tag{72}
\]
When $\tau = \sigma(\xi)$, since the three equations in (61) that are used to derive (65) are essentially the identity (71) with reparameters of $x, y, u$ and $v$, we can substitute (72) into the dBKP (65) where $\tau = \sigma(\xi)$, and we arrive at the following equality
\[
\sigma(x - y) \sigma(v - x) \sigma(y - v) \sigma(u + x + y + v) \sigma(u - x - y - v)
+ \phi(x + v) \sigma^2(v + x) \sigma(y + v) \sigma(x + y) \sigma(v - x) \sigma(u + y) \sigma(u - y) \sigma(u + y)
+ \phi(y + v) \sigma^2(y + v) \sigma(v + x) \sigma(x + y) \sigma(y - v) \sigma(u - x) \sigma(u + x)
+ \phi(x + y) \sigma^2(x + y) \sigma(v + x) \sigma(y + v) \sigma(x - y) \sigma(u - v) \sigma(u + v) = 0.
\tag{73}
\]
The latter elliptic identity is a consequence of the derivation of the dBKP equation, relying on the fact that $\tau = \sigma(\xi)$ is a solution, and obtained by substituting (72) and
\[
a - b = x - y, \quad b - c = v - x, \quad c - a = y - v,
\]
\[
a + b = v + (x + y + v), \quad a + c = x + (x + y + v), \quad b + c = y + (x + y + v),
\]
\[
\tau = \sigma(\xi) = \sigma(u - (x + y + v)), \quad \widehat{\tau} = \sigma(u + (x + y + v)),
\]
\[
\widehat{\tau} = \sigma(u - y), \quad \widehat{\tau} = \sigma(u - x), \quad \widehat{\tau} = \sigma(u - v),
\]
\[
\widehat{\tau} = \sigma(u + y), \quad \widehat{\tau} = \sigma(u + x), \quad \widehat{\tau} = \sigma(u + v).
\]
The identity (73) demonstrates that at a basic level, the discrete equations can be interpreted as addition formulæ, albeit of a special type, for the relevant functions; in the present case for the Weierstrass $\sigma$ and $\wp$ functions.

5. Concluding remarks

We have shown that under special (i.e. reflection) symmetries (16) the dBKP equation (2) can be expressed as a linear combination of the dAKP equation (1) and their reflected symmetric forms (17). This leads to a common subset of solution spaces of the dAKP equation (1) and the dBKP equation (2), which is different from the Pfaffian type link (11) by coordinates reduction. As argued earlier, in a sense such solutions are reducible, as they obey simultaneously two different partial difference equations, each of which allow for in principle different solution classes. Nonetheless, we conjecture that these solutions give an insight into the elliptic parametrisation of the dBKP equation which was unknown hitherto.

We also checked the case of 4D equations, comprising the higher-order equations in the relevant dKP hierarchies. Since the 4D dAKP (22) and 4D dBKP (24) are direct results of the 4D consistency of the dAKP and dBKP, respectively, the two 4D lattice equations allow symmetric $\tau$ function solutions as well. In addition, the 4D dBKP is connected to the 4D dAKP as a linear combination of the latter and its symmetric deformations.

It is also remarkable that the plane wave factors entering in the symmetric $\tau$ functions in section 3 (e.g. (39b)) coincide with the plane wave factors, and their corresponding multi-dimensional extensions, of the ABS list of lattice equations, [1], in the parametrisation that allows their uniform treatment of soliton solutions, cf [15, 28]. This explains why the dAKP and its reflected symmetric forms frequently (sometimes simultaneously) appear in the bilinearisations of the ABS equations, e.g. (4.7) in [3], (5.20a, b) in [8], and (3.15) in [29]. This also implies a possible yet uncovered link between the dBKP equation and ABS lattice equations. Finally, in section 4 we explored the elliptic version of the dBKP equation and we obtained a parametrisation of the dBKP equation (65) with elliptic coefficients and its gauge equivalent form (68). Especially in this elliptic case it would be interesting to establish whether there are non-symmetric solutions of the KP equation that would obey a relation of the type (11). This will be a subject for future investigations.

Data availability statement

No new data were created or analysed in this study.
