ABSTRACT

We calculate the screening corrections to the electron capture rates in dense stars by the relativistically degenerate electron liquid. In order to calculate the screening corrections we adopt the linear response theory, which is widely used in the field of solid-state physics and liquid-metal physics. In particular, we use the longitudinal dielectric function for the relativistically degenerate electron liquid derived by Jancovici. We calculate the screening potential at the position of the nucleus. By using this screening potential one can calculate the screening corrections to the electron capture rates. We present accurate analytic fitting formulae which summarize our numerical results. These fitting formulae will facilitate the application of the present results. The screening corrections to the electron capture rates are typically a few percent.

Subject headings: dense matter — nuclear reactions, nucleosynthesis, abundances — stars: interiors

1. INTRODUCTION

Since the pioneering works of Fuller, Fowler, & Newman (1980, 1982a, 1982b, 1985), calculations of stellar weak-interaction rates have entered an era of precision science. More recently, an authoritative work of Langanke & Martinez-Pinedo (2000) on this subject has appeared.

Since the presupernova stellar evolution and stellar nucleosynthesis critically depend on the details of the stellar weak-interaction rates (e.g., Wanajo et al. 2002), it is extremely important to calculate accurately the screening corrections to the electron capture rates in dense stars due to the relativistically degenerate electron liquid.

This problem has been already addressed by many authors (Couch & Loumos 1974; Takahashi, El Eid, & Hillenbrandt 1978; Gutierrez et al. 1996; Luo & Peng 1996; Bravo & Garcia-Senz 1999). The plasma effects on the chemical potential of the nucleus and hence on the threshold energy for electron capture, in particular, have been discussed by Couch & Loumos (1974), Gutierrez et al. (1996), and Bravo & Garcia-Senz (1999).

In this paper we address ourselves to the calculation of the effective potential energy felt by the relativistically degenerate electron. We use the linear response theory in order to calculate the screening potential caused by the relativistically degenerate electron liquid.

The present paper is organized as follows. In § 2 we calculate the effective potential energy felt by the electron using the longitudinal dielectric function of the relativistically degenerate electron liquid derived by Jancovici (1962). We thereby calculate the screening potential, which is used to calculate the screening corrections to the electron capture rates. In § 3 we summarize the numerical results in the form of analytic fitting formulae that will facilitate the application of the present results. We give concluding remarks in § 4.

2. SCREENING OF THE COULOMB POTENTIAL BY THE RELATIVISTICALLY DEGENERATE ELECTRON LIQUID

The Coulomb corrections to the beta decay rates have been discussed in many standard textbooks on beta decay (e.g., Morita 1973). Some authors (Takahashi et al. 1978; Fuller et al. 1980) have discussed possible importance of the screening effects on the electron capture rates at extremely high densities. Therefore, it is extremely important to calculate accurately the screening corrections to the electron capture rates due to the relativistically degenerate electron liquid.

We consider the density-temperature regime in which the electrons are strongly degenerate. This condition is expressed as (Itoh et al. 1983)

\[ T < T_F = 5.930 \times 10^9 \left[ \left( \frac{Z}{A} \right)^{2/3} \rho_6^{2/3} - 1 \right]^{1/2} \text{ K}, \]

where \( T_F \) is the electron Fermi temperature, \( \rho_6 \) is the mass density in units of \( 10^6 \text{ g cm}^{-3} \), and \( Z \) and \( A \) are the atomic number and mass number of the nucleus considered, respectively. We assume complete pressure ionization. Therefore, no bound electrons will exist around the nucleus. This assumption is valid when the following condition is satisfied (Itoh et al. 1996):

\[ \frac{Z}{A} \rho \geq 0.378Z^3 \text{ (g cm}^{-3}), \]

where \( \rho \) is the mass density.
The potential energy of the electron due to the pure Coulomb potential $-Z e^2/r$ is changed to $V(r)$ because of the screening by the relativistically degenerate electron liquid. In this paper we use the static longitudinal dielectric function due to the relativistically degenerate electron liquid calculated by Jancovici (1962) based on the relativistic random-phase approximation. Jancovici’s static longitudinal dielectric function is written in the form (Itoh et al. 1984)

$$
\epsilon(q, 0) = 1 + \left( \frac{2}{3 \pi^2} \right)^{2/3} \frac{2}{q^2} \left[ \frac{2}{3} (1 + x^2)^{1/2} - \frac{2g^2}{3} \sin^{-1} x \right.
+ (1 + x^2)^{1/2} x^2 + 1 - 3q^2 x^2 \left. \right] \ln \left[ \frac{1 + q}{1 - q} \right]
+ \frac{2g^2 x^2 - 1}{6g x^2} \ln \left[ \frac{q(1 + x^2)^{1/2} + (1 + x^2)^{1/2}}{q(1 + x^2)^{1/2} - (1 + x^2)^{1/2}} \right],
$$

$$
q = \frac{k}{2k_F},
$$

$$
x = \frac{h k_F}{m_e c} = \frac{1}{137.036} \left( \frac{9 \pi}{4} \right)^{1/3} r_s^{-1},
$$

$$
r_s = \frac{a_t}{\hbar^2/m_e c^2} = 1.388 \times 10^{-2} \left( \frac{A}{Z \rho_6} \right)^{1/3},
$$

$$
\frac{4}{3} \pi a_t^3 n_t = 1,
$$

where $n_e$ is the electron number density. The electron Fermi wavenumber is expressed as

$$
k_F = 2.613 \times 10^{10} \left( \frac{Z}{\Delta} \rho_6 \right)^{1/3} \text{cm}^{-1}.
$$

The ion-sphere radius $a_t$ is written as (Itoh & Kohyama 1993)

$$
\frac{4}{3} \pi a_t^3 n_t = 1,
$$

$$
a_t = 0.7346 \times 10^{-10} \left( \frac{\rho_6}{A} \right)^{-1/3} \text{cm},
$$

where $n_i$ is the ion number density. We also have the relationship

$$
k_F a_t = \left( \frac{9 \pi}{4} \right)^{1/3} Z^{1/3}.
$$

The potential energy of the electron $V(r)$, which takes into account the screening by the relativistically degenerate electron liquid, is written as

$$
V(r) = -\frac{Z e^2}{2 \pi} \int \frac{e^{k \cdot r}}{k^2 e(k, 0)} \, d^3 k
= -\frac{Z e^2 (2k_F)}{2k_F} \left( \frac{2}{\pi} \right) \int_0^{\infty} \frac{\sin[(2k_F)q]}{q e(q, 0)} \, dq.
$$

From equations (8) and (18) we have

$$
2k_F r_{\text{nuc}} = 6.3 \times 10^{-3} Z^{1/3} \rho_6^{1/3}.
$$
From Figure 3 we see that the function $J(R)$ is almost constant for small values of $R$, which corresponds to $2k_F r_{\text{nuc}}$ given by equation (19), when the mass density is not extremely high. This fact justifies our use of $V_s(0)$ for the screening potential at the nuclear radius. When the mass density becomes extremely high, then one should use the value of the screening potential $V_s(r)$ by adopting the value of the function $J(R = 2k_F r_{\text{nuc}})$.

The electron Fermi energy is given by

$$E_F = 0.5110 \left\{ 1 + 1.018 \left( \frac{Z}{A} \right)^{\frac{2}{3}} \rho_0^{\frac{2}{3}} \right\}^{1/2} \ (\text{MeV}) \ .$$

When the electrons are extremely relativistic, we have

$$\frac{V_s(r)}{E_F} \approx 1.460 \times 10^{-2} Z J.$$  \hfill (21)

Therefore, we find that the screening potential at the origin $V_s(0)$ is typically a few percent of the electron Fermi energy. Thus, we conclude that the screening corrections to the electron capture rates by the relativistically degenerate electron liquid are not as great as anticipated by Takahashi et al. (1978) and also by Fuller et al. (1980).

In passing, it is interesting to compare our present detailed calculation with the Fermi-Thomas model, which is generally more crude than the random-phase approximation that has been adopted in the present paper (Pines & Nozières 1966). In the Fermi-Thomas model the screening potential at the origin is expressed as (Pines & Nozières 1966)

$$[V_s(0)]_{\text{FT}} = Z e^2 k_{\text{FT}},$$  \hfill (22)

where $k_{\text{FT}}$ is the Fermi-Thomas screening wave number. When the electrons are extremely relativistic, the Fermi-Thomas screening wavenumber is expressed as (Flowers & Itoh 1976)

$$\frac{k_{\text{FT}}}{2k_F} \approx \frac{1}{2} \left( \frac{4}{\pi} \frac{1}{137.036} \right)^{1/2} = 0.0482.$$  \hfill (23)

By comparing with Figures 2, 3, and 4, we find that the prediction of the Fermi-Thomas model is quite good (the accuracy is about 7%) for the present problem when the electrons are extremely relativistic.

### 3. ANALYTIC FITTING FORMULAE

In this section we present accurate analytic fitting formulae for $J(R)$ in order to facilitate the application of the numerical results obtained in the present paper. We have carried out the numerical calculations of $J(R)$ for $0.00001 \leq r_s \leq 0.1$, $0 \leq R \leq 50.0$. We express the analytic fitting formula by

$$J(r_s, R) = \sum_{i,j=0}^{10} a_{ij} s^i u^j,$$  \hfill (24)

$$s \equiv \frac{1}{2} \left( \log_{10} r_s + 3 \right),$$  \hfill (25)

$$u \equiv \frac{1}{25.0} (R - 25.0).$$  \hfill (26)

The coefficients $a_{ij}$ are presented in Table 1. The accuracy of the fitting is generally better than 0.1%.

The value of $J(r_s, R)$ for $R = 0$ is of course obtained by the fitting formulae given in equations (24), (25), and (26).

### 4. CONCLUDING REMARKS

We have studied the screening corrections to the electron capture rates by the relativistically degenerate electron liquid. In particular, we have calculated the screening potential caused by the relativistically degenerate electron by using Jancovici’s (1962) static longitudinal dielectric function. We have found that the screening potential is typically a few percent of the electron Fermi energy. Hence, we conclude that the screening corrections to the electron capture rates at high densities are not as great as anticipated by Takahashi et al. (1978) and also by Fuller et al. (1980).

We have presented accurate analytic fitting formulae that will be useful when one wishes to apply the present results to the calculations of the screening corrections to the electron capture rates at high densities.

We wish to thank K. Nomoto for drawing our attention to the present important problem. We are grateful to Y. Takada for clarifying the validity of the linear response theory in the present problem. We also thank Y. Oyanagi for allowing us to use the least-squares fitting program SALS. This work is financially supported in part by Grants-in-Aid of the Japanese Ministry of Education, Culture, Sports, Science, and Technology under contracts 13640245 and 13740129.
