Abstract
In this paper, a delayed SIQR epidemic model with vaccination and elimination hybrid strategies is analysed under a white noise perturbation. We prove the existence and the uniqueness of a positive solution. Afterwards, we establish a stochastic threshold \( R_s \) in order to study the extinction and persistence in mean of the stochastic epidemic system. Then we investigate the existence of a stationary distribution for the delayed stochastic model. Finally, some numerical simulations are presented to support our theoretical results.

1 Introduction

Governments has always made the public health policy as a priority and adopted decisions, plans and actions to save human lives from deadly infectious diseases. For
this matter, computational biologists study the dynamics of epidemics to prevent and control the infection from spreading in the population [1,2,6]. Historically, in the 14th century, the authorities of the city of Venice have installed a measure of isolation to enter and exit its ports, where every crew in every ship was inspected, once the whole personal have no symptoms, then they could be cleared out to land. This idea is adopted as a major measure to prevent infectious diseases such as Ebola and Malaria from spreading. Nowadays, every well equipped hospital has a number of rooms and halls dedicated for the isolation of infected individuals. In addition, the authorities can put their people under quarantine. This decision has a significant impact on the basic reproduction number, which leads us to the extinction of the infectious disease. Recently, the quarantine measure has proven to be efficient in the extinction of the COVID19 disease in China, which let many countries to adopt this strategy in absence of vaccine or a cure to the new Corona virus. In order to understand the effect of quarantine on the behavior of the epidemics, Heathcote [13] proposed a model with quarantine to describe isolated individuals in the compartmental model followed by other papers such as [5,27].

On the other hand, a new type of delayed stochastic models are proposed to describe the role of time delay in reality which leads to a more complex behavior of the stability of the dynamic system. This concept is described as a temporary immunity in [1,10,12] and as a vaccine effect in [8,9]. However, the temporary immunity can impact also the quarantined individuals. Therefore delayed stochastic epidemic models are concerning the persistence in mean, ultimate boundedness and permanence [5] or the asymptotic behavior around the equilibrium points of the infectious diseases models. In [15], the authors obtained sufficient conditions for the existence and uniqueness of stationary distribution for a delayed stochastic differential equations with positivity constraints and applied theoretical results for biochemical reaction system. Also, Zhang and Yuan [28] used Lyapunov analysis method to investigate the existence of stationary distribution of a stochastic delayed chemostat model. Therefore, it is important to investigate a relatively weak characteristic for a delayed stochastic epidemic model.

In recent years, epidemic models with quarantine for the have been proposed [23, 25,26]. On the other hand, for the modelling of the environmental noise. In [3,4,16,20, 24,29] perturbed systems with white noise and isolation for population dynamics are considered. Liu et al. [22] investigated a SIQR epidemic model with telegraph noise to study the influence of isolation for a compartmental SIR model, where they established a stochastic threshold for the extinction, persistence in mean and obtained sufficient conditions for the existence of positive recurrence of the solutions. By constructing a suitable stochastic Lyapunov function to the epidemic model with regime switching.

Therefore, in order to reflect more the reality we introduced the notion of delay, vaccine and elimination in an SIQR epidemic model. Hence, we propose the following triple delayed SIQR epidemic model with vaccination and isolation strategies

\[
\dot{S} = A - \beta S(t)I(t) - (\mu + p)S(t) + pS(t - \tau_1)e^{-\mu \tau_1} + \gamma I(t - \tau_2)e^{-\mu \tau_2} + \varepsilon Q(t - \tau_3)e^{-\mu \tau_3}, \\
\dot{I} = \beta S(t)I(t) - (\mu + \alpha_1 + \delta + \gamma)I(t), \\
\dot{Q} = \delta I(t) - (\mu + \alpha_2 + \varepsilon)Q(t),
\]

\(\xi\) Springer
\[
\begin{align*}
\dot{S} &= \gamma I(t) + pS(t) + \varepsilon Q(t) - \mu R(t) - pS(t - \tau_1)e^{-\mu \tau_1} \\
&\quad - \gamma I(t - \tau_2)e^{-\mu \tau_2} - \varepsilon Q(t - \tau_3)e^{-\mu \tau_3},
\end{align*}
\] (1)

The compartments susceptible, infected, quarantined or isolated, and recovered are denoted by \(S(t), I(t), Q(t)\) and \(R(t)\), respectively. The parameter \(A\) represents the population recruitment rate, \(\mu\) denotes the natural death rate of \(S, I, Q\) and \(R\) compartments, \(\beta\) denotes the transmission coefficient from susceptible to infected individuals, \(\gamma\) describes the recovery rate of the infective individuals, \(\alpha_1\) and \(\alpha_2\) represents the death rate for infected and quarantined individuals because of infection complications, \(p\) stands for the proportional coefficient of vaccinated for the susceptible, \(\delta\) denotes the rate of infectious individuals who were isolated, \(\varepsilon\) represents the recovered people coming from isolation. The time \(\tau_1 > 0\) represents the delay for the efficiency of vaccine. The term \(S(t - \tau_1)e^{-\mu \tau_1}\) reflects the fact that some individuals remains susceptible even after the vaccine for a specific time. The time \(\tau_2 > 0\) is the length of the immunity period. The term \(I(t - \tau_2)e^{-\mu \tau_2}\) represents the individuals who became susceptible because of the lose of immunity for a specific time. The time \(\tau_3 > 0\) denotes the delay for isolated individuals to get back their immunity. The term \(Q(t - \tau_3)e^{-\mu \tau_3}\) represents the individuals coming out from isolation with immunity impairment. The basic reproduction number of the system (1) is

\[
R_0 = \frac{\beta A}{(\mu + p(1 - e^{-\mu \tau_1}))(\mu + \alpha_1 + \delta + \gamma)}. \tag{2}
\]

Next, we establish the following delayed stochastic SIQR epidemic model with vaccination and elimination strategies

\[
\begin{align*}
\dot{S} &= [A - \beta S(t)I(t) - (\mu + p)S(t) + pS(t - \tau_1)e^{-\mu \tau_1} + \gamma I(t - \tau_2)e^{-\mu \tau_2} \\
&\quad + \varepsilon Q(t - \tau_3)e^{-\mu \tau_3}]dt + \sigma_1 S(t)dB_1(t), \\
\dot{I} &= [\beta S(t)I(t) - (\mu + \alpha_1 + \delta + \gamma)I(t)]dt + \sigma_2 I(t)dB_2(t), \\
\dot{Q} &= [\delta I(t) - (\mu + \alpha_2 + \varepsilon)Q(t)]dt + \sigma_3 Q(t)dB_3(t), \\
\dot{R} &= [\gamma I(t) + pS(t) + \varepsilon Q(t) - \mu R(t) - pS(t - \tau_1)e^{-\mu \tau_1} \\
&\quad - \gamma I(t - \tau_2)e^{-\mu \tau_2} - \varepsilon Q(t - \tau_3)e^{-\mu \tau_3}]dt + \sigma_4 R(t)dB_4(t),
\end{align*}
\] (3)

where, \(B_i(t)\) are independent standard Brownian motions defined on a complete probability space \((\Omega, \mathcal{F}, \mathbb{P})\) with a filtration \(\{\mathcal{F}_t\}_{t \geq 0}\) satisfying the usual conditions and \(\sigma_i\) for \(i = 1, 2, 3, 4\) represent the volatility perturbations.

We define the differential operator \(L\), associated with the following general \(d\)-dimensional stochastic system

\[
\begin{align*}
\dot{X}(t) &= F(t, X(t), X(t - \tau))dt + G(t, X(t))dB(t), \quad \text{for all } t \geq -\tau, \ \tau \geq 0, \tag{4}
\end{align*}
\]

with the initial condition \(X(s) = \eta(s)\) for \(s \in [-\tau, 0]\), \(\eta \in C([-\tau, 0]; \mathbb{R}^d_+)\) and \(\eta(s) > 0\), where \(F(t, X(t), X(t - \tau))\) is a function on \(\mathbb{R}^d\) defined in \([-\tau, +\infty[ \times \mathbb{R}^d\), \(G(t, X(t))\) is a \(d \times m\) matrix, \(F\) and \(G\) are locally Lipschitz functions in \(x\) and \(B(t)\)
is an $d$-dimensional Wiener process. The differential operator $L$, acts on a function $V \in C^{1,2}(C([-\tau, 0]; \mathbb{R}^d_+) \times [-\tau, \infty); \mathbb{R}_+)$, as follows

$$LV(t, X) = V_t(t, X) + V_X(t, X) F(t, X(t), X(t - \tau)$$

$$+ \frac{1}{2} \text{trace} \left[ G^T(t, X) V_{XX}(X, t) G(X, t) \right].$$

By Itô’s formula

$$dV(t, x(t)) = LV(t, X(t))dt + V_X(t, X(t))G(t, X(t))dB(t),$$

where

$$V_t = \frac{\partial V}{\partial t}, \quad V_x = \left( \frac{\partial V}{\partial x_1}, \frac{\partial V}{\partial x_2}, \ldots, \frac{\partial V}{\partial x_d} \right), \quad V_{xx} = \left( \frac{\partial^2 V}{\partial x_i \partial x_j} \right)_{d \times d}.$$

For any $X \in \mathbb{R}^3$, the norm $|X|$, as usual, is given by $|X| = \sqrt{X_1^2 + X_2^2 + X_3^2}$.

This work is organized as follows. In Sect. 2, Existence and uniqueness of a global positive solution is shown. In Sect. 3, the stochastic threshold is investigated between the extinction and persistence in man. In Sect. 4, we prove sufficient conditions for the existence of a unique stationary distribution for the delayed stochastic SIQR epidemic model. In Sect. 5, numerical simulations are given to support the theoretical results.

## 2 Existence and uniqueness of the global positive solution

In this section, we prove that the model (3) has a local positive solution. Then we investigate the global positivity of the solution.

Throughout this work, we will reduce our stochastic system (3) using the three first equations since they do not depend on $R(t)$. The fourth equation can be dropped without loss of generality.

Let $\tau = \max\{\tau_1, \tau_2, \tau_3\}$. We denote

$$\mathbb{R}^3_+ = \left\{ (S, I, Q) \in \mathbb{R}^3 : S > 0, \quad I > 0, \quad Q > 0 \right\}.$$

and let $C = C([-\tau, 0], \mathbb{R}^3_+)$ be the Banach space of continuous functions mapping from the interval $[-\tau, 0]$ into $\mathbb{R}^3_+$ equipped by the norm $||\phi|| = \sup_{-\tau \leq \theta \leq 0} |\phi(\theta)|$. We set the initial conditions of system (3) to be

$$S(\theta) = \phi_1(\theta), \quad I(\theta) = \phi_2(\theta), \quad Q(\theta) = \phi_3(\theta),$$

$$\phi_i(\theta) > 0, \quad \theta \in [-\tau, 0], \quad i = 1, 2, 3,$$

$$(\phi_1, \phi_2, \phi_3) \in C.$$ (5)

 Springer
Theorem 1  For any given initial value \((S(0), I(0), Q(0)) \in \mathbb{R}_+^3\), there is a positive 
unique solution \((S(t), I(t), Q(t))\) of model (3) on \(t \geq 0\) and the solution will remain 
in \(\mathbb{R}_+^3\) with probability 1.

Proof  Since the coefficients of the system (3) are locally Lipschitz continuous, for any 
given initial value \((S(0), I(0), Q(0)) \in \mathbb{R}_+^3\), there is a unique local solution positive 
\((S(t), I(t), Q(t))\) on \(t \in [\tau, \tau_e]\), where \(\tau = \max\{\tau_1, \tau_2, \tau_3\}\) and \(\tau_e\) is the explosion 
time. Now, we show that the solution is global. We have only to prove that \(\tau_e = \infty\) a.s.
Consider an \(\varepsilon_0 > 0\) such that \((S(0) > \varepsilon_0, I(0) > \varepsilon_0, Q(0) > \varepsilon_0)\), then we define the 
stop-stopping time as follows 
\[
\tau_{\tilde{\varepsilon}} = \inf\{t \in [0, \tau_e) : S(t) \leq \tilde{\varepsilon}, \text{ or } I(t) \leq \tilde{\varepsilon}, \text{ or } Q(t) \leq \tilde{\varepsilon}\}, \quad \forall \tilde{\varepsilon} > 0 \text{ such that } \tilde{\varepsilon} \leq \varepsilon_0.
\]
Throughout this paper we set \(\inf \emptyset = \infty\) (\(\emptyset\) denotes the empty set). It’s clear that, \(\tau_{\tilde{\varepsilon}}\) 
is increasing as \(\tilde{\varepsilon} \rightarrow 0\). Set \(\tau_0 = \lim_{\tilde{\varepsilon} \rightarrow 0} \tau_{\tilde{\varepsilon}}\). Obviously, \(\tau_0 \leq \tau_e\) a.s. If \(\tau_0 = \infty\) a.s. is 
true, then \(\tau_e = \infty\) a.s. and \((S(t), I(t), Q(t)) \in \mathbb{R}_+^3\) a.s. for \(t \geq 0\). In other words, to 
complete the proof it is required to show that \(\tau_0 = \infty\) a.s. If this statement is false, 
then there exist a pair of constants \(T > 0\) and \(\delta \in (0, 1)\) such that \(\mathcal{P}\{\tau_0 \leq T\} > \delta\). 
Thus there is an \(\varepsilon_1 > 0\) such that 
\[
\mathcal{P}\{\tau_{\tilde{\varepsilon}} \leq T\} \geq \delta \quad \forall \tilde{\varepsilon} \leq \varepsilon_1.
\]
Consider the \(C^2\)-function \(V_1 : \mathbb{R}_+^3 \rightarrow \mathbb{R}\) as follows 
\[
V_1(S, I, Q) = \log S(t) + \log I(t) + \log Q(t) - \log \phi_1(\theta) - \log \phi_2(\theta) - \log \phi_3(\theta),
\]
(6)

Applying Itô’s formula on (6) for all \(t \in [0, \tau_{\tilde{\varepsilon}})\) and all \(\omega \in \{\tau_{\tilde{\varepsilon}} < T\}\), we obtain 
\[
V_1(S, I, Q) = \int_0^t \left[ \frac{A}{S(s)} - (\mu + p) - \beta I(s) + \frac{pS(s - \tau_1)e^{-\mu\tau_1}}{S(s)} + \frac{\gamma I(s - \tau_2)e^{-\mu\tau_2}}{S(s)} + \frac{\varepsilon Q(s - \tau_3)e^{-\mu\tau_3}}{S(s)} - \frac{\sigma_1^2}{2} \right] ds + \int_0^t \left[ \frac{\beta S(s) - (\mu + \alpha_1 + \delta + \gamma) - \frac{\sigma_2^2}{2}}{S(s)} \right] ds \\
+ \int_0^t \left[ \frac{\delta I(s)}{Q(s)} - (\mu + \alpha_2 + \varepsilon) - \frac{\sigma_3^2}{2} \right] ds + \sigma_1 B_1(t) + \sigma_2 B_2(t) + \sigma_3 B_3(t) \\
\geq - \int_0^t \left[ 3\mu + p + \alpha_1 + \alpha_2 + \delta + \gamma + \varepsilon + \frac{\sigma_1^2 + \sigma_2^2 + \sigma_3^2}{2} + \beta I(s) \right] ds + \sigma_1 B_1(t) \\
+ \sigma_2 B_2(t) + \sigma_3 B_3(t). \quad (7)
\]
According to the stopping time \(\tau_{\tilde{\varepsilon}}\), for almost all \(\omega \in \{\tau_{\tilde{\varepsilon}} < T\}\) at least one component 
of \((S(\tau_{\tilde{\varepsilon}}), I(\tau_{\tilde{\varepsilon}}), Q(\tau_{\tilde{\varepsilon}}))\) is equal to \(\tilde{\varepsilon}\). Thus, 
\[
\lim_{\tilde{\varepsilon} \rightarrow 0} V_1(S(\tau_{\tilde{\varepsilon}}), I(\tau_{\tilde{\varepsilon}}), Q(\tau_{\tilde{\varepsilon}})) = -\infty \quad (8)
\]
Letting \( t \to \tau \tilde{\varepsilon} \) in (7), we obtain

\[
- \left(3\mu + p + \alpha_1 + \alpha_2 + \delta + \gamma + \varepsilon + \frac{1}{2} (\sigma_1^2 + \sigma_2^2 + \sigma_3^2)\right) \tau \tilde{\varepsilon} \\
- \beta \int_0^{\tau \tilde{\varepsilon}} I(s) \, ds + \sigma_1 B_1(\tau \tilde{\varepsilon}) + \sigma_2 B_2(\tau \tilde{\varepsilon}) + \sigma_3 B_3(\tau \tilde{\varepsilon}) > -\infty.
\]  

From (8) and extending \( \tilde{\varepsilon} \) to zero in (9) contradict our assumption, consequently, \( \tau_0 = \tau_e = +\infty \) a.s. \( \square \)

3 Investigation of a stochastic threshold

In this section, we investigate a stochastic threshold for the extinction and the persistence in mean which represent an important issues to study the dynamics of the disease. Firstly, we will focus on the following lemmas before investigating a stochastic threshold of the stochastic system (3).

**Lemma 1** Let \((S(t), I(t), Q(t))\) be a solution of system (3) with any initial value \((S(\xi_1) \geq 0, I(\xi_2) \geq 0, Q(\xi_3) \geq 0\) for all \(\xi_1 \in [-\tau_1, 0), \xi_2 \in [-\tau_2, 0), \xi_3 \in [-\tau_3, 0)\) with \(S(0) > 0, I(0) > 0, Q(0) > 0\), then

\[
\lim_{t \to \infty} \frac{S(t) + I(t) + Q(t) + pS(t - \tau_1)e^{-\mu t_1} + \gamma I(t - \tau_2)e^{-\mu t_2} + \varepsilon Q(t - \tau_3)e^{-\mu t_3}}{t} = 0 \text{ a.s.}
\]  

Moreover

\[
\lim_{t \to \infty} \frac{S(t)}{t} = 0, \quad \lim_{t \to \infty} \frac{I(t)}{t} = 0, \quad \lim_{t \to \infty} \frac{Q(t)}{t} = 0, \quad \lim_{t \to \infty} \frac{e^{-\mu t} \int_{t-\tau_1}^{t} e^{\mu s} S(s) \, ds}{t} = 0
\]

\[
\lim_{t \to \infty} \frac{e^{-\mu t} \int_{t-\tau_2}^{t} e^{\mu s} I(s) \, ds}{t} = 0, \quad \lim_{t \to \infty} \frac{e^{-\mu t} \int_{t-\tau_3}^{t} e^{\mu s} Q(s) \, ds}{t} = 0 \text{ a.s.}
\]

**Proof** Let

\[
V_1(t) = S(t) + I(t) + Q(t) + pe^{-\mu t} \int_{t-\tau_1}^{t} e^{\mu s} S(s) \, ds + \gamma e^{-\mu t} \int_{t-\tau_2}^{t} e^{\mu s} I(s) \, ds
\]

\[
+ \varepsilon e^{-\mu t} \int_{t-\tau_3}^{t} e^{\mu s} Q(s) \, ds.
\]

Define

\[
V_2(V_1) = (1 + V_1)^{\theta},
\]

\( \square \) Springer
where \( \theta \) is a positive constant to be determined later. Applying Itô’s formula on \( V_2 \), we get

\[
\begin{align*}
    dV_2(V_1) &= \mathcal{L}V_2(V_1)dt + \theta(1 + V_1)^{\theta-1}(\sigma_1 S(t)dB_1(t) + \sigma_2 I(t)dB_2(t) \\
    &\quad + \sigma_3 Q(t)dB_3(t)),
\end{align*}
\]

where

\[
\mathcal{L}V_2(V_1)
\begin{align*}
    &= \theta(1 + V_1)^{\theta-1}[A - \mu S(t) - (\mu + \alpha_1)I(t) - (\mu + \alpha_2)Q(t) \\
    &\quad - \mu pe^{-\mu t}\int_{t-\tau_1}^{t} e^{\mu s}S(s)ds - \mu \gamma e^{-\mu t}\int_{t-\tau_2}^{t} e^{\mu s}I(s)ds - \mu e^{-\mu t}\int_{t-\tau_3}^{t} e^{\mu s}Q(s)ds \\
    &\quad + \frac{\theta(\theta - 1)}{2}(1 + V_1)^{\theta-2}(\sigma_1^2 S^2 + \sigma_2^2 I^2 + \sigma_3^2 Q^2) \\
    &\quad \leq \theta(1 + V_1)^{\theta-2}((1 + V_1)[A - \mu V_1 - \alpha_1 I(t) + \alpha_2 Q(t)] \\
    &\quad + \frac{\theta - 1}{2}(\sigma_1^2 S^2 + \sigma_2^2 I^2 + \sigma_3^2 Q^2).\end{align*}
\]

Let \( \sigma^2 = \sigma_1^2 \vee \sigma_2^2 \vee \sigma_3^2 \). Therefore, we obtain

\[
\begin{align*}
\mathcal{L}V_2(V_1) &\leq \theta(1 + V_1)^{\theta-2}\left\{ (1 + V_1)\left[ A - \mu V_1 \right] + \left( \frac{\theta - 1}{2} \right) \sigma^2 V_1^2 \right\} \\
    &\leq \theta(1 + V_1)^{\theta-2}\left\{ \left( \mu - \sigma^2 \frac{\theta - 1}{2} \right) V_1^2 + (A - \mu)V_1 + A \right\}.
\end{align*}
\]

Choose \( \theta > 1 \) such that \( \mu - \left( \frac{\theta - 1}{2} \right) \sigma^2 : = \nu > 0 \) then

\[
\mathcal{L}(V_2(V_1)) \leq \theta(1 + V_1)^{\theta-2}\{-\nu V_1^2 + (A - \mu)V_1 + A\}.
\]

Yields that

\[
\begin{align*}
    d(V_2(V_1)) &\leq \theta(1 + V_1)^{\theta-2}\{-\nu V_1^2 + (A - \mu)V_1 + A\}dt \\
    &\quad + \theta(1 + V_1)^{\theta-1}[\sigma_1 SdB_1(t) + \sigma_2 IdB_2(t) + \sigma_3 QdB_3(t)].
\end{align*}
\]

Therefore, for \( 0 \leq k \leq \nu \theta \), we get

\[
\begin{align*}
    E(e^{kt}V_2(V_1)) &= V_2(V_1(0)) + E \int_{0}^{t} \mathcal{L}(e^{ks}V_2(V_1(s)))ds,
\end{align*}
\]

where

\[
\mathcal{L}(e^{kt}V_2(V_1)) = ke^{kt}V_2(V_1) + e^{kt} \mathcal{L}V_2(V_1)
\]

\[
\begin{align*}
    &\leq \theta e^{kt}(1 + V_1)^{\theta-2}\left\{ \frac{k}{\theta}(1 + V_1)^2 - \nu V_1^2 + (A - \mu)V_1 + A \right\}
\end{align*}
\]
\[
\begin{align*}
\theta e^{kt} (1 + V_1)^{\theta-2} \left( -\left( v - \frac{k}{\theta} \right) V_1^2 + \left( A - \mu + \frac{2k}{\theta} \right) V_1 + A \right) \leq \theta e^{kt} H,
\end{align*}
\]

with

\[
H := \sup_{V_1 \in \mathbb{R}_+} (1 + V_1)^{\theta-2} \left[ -\left( v - \frac{k}{\theta} \right) V_1^2 + \left( A - \mu + \frac{2k}{\theta} \right) V_1 + A \right].
\]

Accordingly to (14), we get

\[
E[e^{kt}(1 + V_1(t))^{\theta}] \leq (1 + V_1(0))^{\theta} + \frac{\theta H}{k} e^{kt}. \tag{15}
\]

Knowing that \( V_1(t) \) is continuous, yields that there is a positive constant \( K \) such that

\[
E[(1 + V_1(t))^{\theta}] \leq K \quad \text{for all } t \geq 0. \tag{16}
\]

Using (13) and according to Burkholder–Davis–Gundy inequality, for a sufficiently small \( \varrho > 0 \), \( k = 1, 2, \ldots \) and for a positive constant \( c_1 \), we have

\[
E \left[ \sup_{k \varrho \leq t \leq (k+1) \varrho} (1 + V_1(t))^{\theta} \right] \leq E[(1 + V_1(k \varrho))^{\theta} + \gamma_1 + \gamma_2,
\]

in which

\[
\gamma_1 = E \left[ \sup_{k \varrho \leq t \leq (k+1) \varrho} \left( \int_{k \varrho}^{t} \theta(1 + V_1(s))^{\theta-2} \left[ -v V_1(s)^2 + (A - \mu) V_1(s) + A \right] ds \right) \right]
\]

\[
\leq c_1 E \left[ \int_{k \varrho}^{(k+1) \varrho} (1 + V_1(s))^{\theta} ds \right]
\]

\[
\leq c_1 \varrho E \left[ \sup_{k \varrho \leq t \leq (k+1) \varrho} (1 + V_1(t))^{\theta} \right],
\]

and

\[
\gamma_2 = E \left[ \sup_{k \varrho \leq t \leq (k+1) \varrho} \left( \int_{k \varrho}^{t} \theta(1 + V_1(s))^{\theta-1} \left( \sigma_1 S(s) d B_1(s) + \sigma_2 I(s) d B_2(s) + \sigma_3 Q(s) d B_3(s) \right) \right) \right]
\]

\[
\leq \sqrt{32} E \left[ \int_{k \varrho}^{(k+1) \varrho} \theta^2 (1 + V_1(s))^{2(\theta-1)} \left( \sigma_1^2 S^2(s) + \sigma_2^2 I^2(s) + \sigma_3^2 Q^2(s) \right) ds \right]^{\frac{1}{2}}
\]

\[
\leq \sqrt{32} \varrho \sigma \theta \frac{1}{2} E \left[ \sup_{k \varrho \leq t \leq (k+1) \varrho} (1 + V_1(t))^{\theta} \right].
\]
Thus
\[
E \left[ \sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1(t))^\theta \right] \\
\leq E[(1 + V_1(k\varrho))^\theta] + \left[ c_1\varrho + \sqrt{32\theta\sigma\delta^2} \right] E \left[ \sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1(t))^\theta \right].
\]

We choose \( \varrho > 0 \) as \( c_1\varrho + \sqrt{32\theta\sigma\varrho^2} \leq \frac{1}{2} \) and from (16) we have
\[
E \left[ \sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1)^\theta \right] \leq 2K.
\]

Choosing \( \varepsilon_u > 0 \) as an arbitrary number and applying Chebyshev’s inequality, we get
\[
P \left\{ \sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1)^\theta > (k\varrho)^{1+\varepsilon_u} \right\} \leq \frac{E \left[ \sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1(t))^\theta \right]}{(k\varrho)^{1+\varepsilon_u}} \leq \frac{2K}{(k\varrho)^{1+\varepsilon_u}}.
\]

For almost all \( \sigma \in \Omega \) and by Borel–Cantelli’s lemma, we have
\[
\sup_{k\varrho \leq t \leq (k + 1)\varrho} (1 + V_1(t))^\theta \leq (k\varrho)^{1+\varepsilon_u}, \tag{17}
\]

holds for all finite \( k \). Therefore, there exists for almost all \( \omega \in \Omega \), a random integer \( k_0(\omega) \), where (17) is satisfied for \( k \geq k_0 \). Thus, for almost all \( \omega \in \Omega \), if \( k \geq k_0 \) and \( k\varrho \leq t \leq (k + 1)\varrho \), we have
\[
\frac{\log(1 + V_1(t))^\theta}{\log t} \leq \frac{(1 + \varepsilon_u)\log(k\varrho)}{\log(k\varrho)} = 1 + \varepsilon_u.
\]

Then
\[
\limsup_{t \to \infty} \frac{\log(1 + V_1(t))^\theta}{\log t} \leq 1 + \varepsilon_u \text{ a.s}
\]

Let \( \varepsilon_u \to 0 \), then
\[
\limsup_{t \to \infty} \frac{\log(1 + V_1(t))^\theta}{\log t} \leq 1 \text{ a.s.}
\]
Hence
\[
\limsup_{t \to \infty} \frac{\log V_2(t)}{\log t} \leq \limsup_{t \to \infty} \frac{\log(1 + V_1(t))^{\theta}}{\log t} \leq \frac{1}{\theta}, \text{ a.s}
\]
That is to say, for any small \(0 < \xi < 1 - \frac{1}{\theta}\), there exists a constant \(T = T(\omega)\) and a set \(\Omega_\xi\) as \(P(\Omega_\xi) \geq 1 - \xi\), and for \(t \geq T, \omega \in \Omega_\xi\), we get
\[
\log V_1(t) \leq \left(\frac{1}{\theta} + \xi\right) \log t
\]
Therefore
\[
\limsup_{t \to \infty} \frac{V_1(t)}{t} \leq \limsup_{t \to \infty} \frac{\frac{1}{\theta} + \xi}{t} = 0,
\]
where together with the positivity of the solution, we get
\[
\lim_{t \to \infty} \frac{V_1(t)}{t} = 0 \text{ a.s}
\]
In which, we get (10). Finally, we obtain
\[
\lim_{t \to \infty} \frac{S(t)}{t} = \lim_{t \to \infty} \frac{I(t)}{t} = \lim_{t \to \infty} \frac{Q(t)}{t} = \lim_{t \to \infty} \frac{e^{-\mu t} \int_{t-t_1}^{t} e^{\mu s} S(s) ds}{t} = \lim_{t \to \infty} \frac{e^{-\mu t} \int_{t-t_1}^{t} e^{\mu s} I(s) ds}{t} = 0 \text{ a.s. Hence, this completes the proof.}
\]

**Lemma 2** Let \((S(t), I(t), Q(t))\) be the solution of system (3) With any given initial condition \(S(\xi_1) \geq 0, I(\xi_2) \geq 0\) and \(Q(\xi_3) \geq 0\) for all \(\xi_1 \in [-\tau_1, 0], \xi_2 \in [-\tau_2, 0]\) and \(\xi_3 \in [-\tau_3, 0]\) with \(S(0), I(0)\) and \(Q(0) > 0\) then
\[
\lim_{t \to \infty} \frac{\int_0^t S(s) dB_1(s)}{t} = \lim_{t \to \infty} \frac{\int_0^t I(s) dB_2(s)}{t} = \lim_{t \to \infty} \frac{\int_0^t Q(s) dB_3(s)}{t} = 0. \tag{18}
\]

**Proof** Let \(1 < \theta < 1 + \frac{2\mu}{\sigma}\) and denote \(X_i(t) = \int_0^t x_i(s) dB_i(t)\) with \(i = \{1, 2, 3\}\) and \(x_i(t) \in [S(t), I(t), Q(t)]\).

According to the Burkholder–Davis–Gundy inequality (Theorem 7.3 [21]), we have
\[
E \left[ \sup_{0 \leq s \leq t} |X_i(s)|^\theta \right] \leq C_\theta E \left[ \int_0^t x_i^2(r) dr \right]^\frac{\theta}{2} \leq C_\theta t^\frac{\theta}{2} E \left[ \sup_{0 \leq r \leq t} x_i^2(r) \right]^\frac{\theta}{2} \leq 2M_i C_\theta t^\frac{\theta}{2}, \tag{19}
\]
where $M_i$ are positive constants. Now, let $\varepsilon X_i$ be an arbitrary positive constant, for $i = \{1; 2; 3\}$, Applying Doob’s martingale inequality (Theorem 3.8 [21]) yields that

$$P \left\{ \omega : \sup_{k \leq t \leq (k+1)} |X_i(t)| > (k)^{\frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}} \right\} \leq \frac{E[|X_i(k+1)|^\theta]}{(k)^{\frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}}} \leq \frac{2M_i C_\theta(k+1)^{\frac{\theta}{2}}}{(k)^{\frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}}}.$$ 

Thus, by Borel–Cantelli lemma, we get that for almost all $\omega \in \Omega$

$$\sup_{k \leq t \leq (k+1)} |X_i(s)|^\theta \leq (k)^{\frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}}. \quad (20)$$

Verified for all finite $k$. Therefore, there exists a positive random integer $k_0(\omega)$, for almost all $\omega \in \Omega$, where (20) satisfied whenever $k \geq k_0$. Thus, for almost all $\omega \in \Omega$, if $k \geq k_0$ and $k \leq t \leq (k+1)$,

$$\frac{\log |X_i(t)|^\theta}{\log t} \leq \left( \frac{1}{2} + \varepsilon X_i + \frac{\theta}{2} \right) \frac{\log(k)}{\log(k)} = \frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}.$$ 

Then

$$\limsup_{t \to \infty} \frac{\log |X_i(t)|}{\log t} \leq \frac{1}{2} + \varepsilon X_i + \frac{\theta}{2}.$$ 

Letting $\varepsilon X_i \to 0$, we get

$$\lim_{t \to \infty} \frac{\log |X_i(t)|}{\log t} \leq \frac{1 + \theta}{2\theta} = \frac{1}{2} + \frac{1}{2\theta}.$$ 

That is to say, for any small $0 < \chi_1 < \frac{1}{2} - \frac{1}{2\theta}$. There exist a positive constant $T = T(\omega) \geq 1 - \chi_1$ and for $t \geq T$, $\omega \in \Omega_{\chi_1}$, we get

$$\ln |X_i| \leq \left( \frac{1}{2\theta} + \chi_1 \right) \ln t,$$

so

$$\limsup_{t \to \infty} \frac{|X_i(t)|}{t} \leq \limsup_{t \to \infty} \frac{t^{\frac{1}{2\theta} + \chi_1}}{t} = 0,$$

Which together with $\liminf_{t \to \infty} \frac{|X_i(t)|}{t} \geq 0$, we get

$$\lim_{t \to \infty} \frac{|X_i(t)|}{t} = 0 \text{ a.s.}$$
yields that
\[
\lim_{t \to \infty} \frac{X_i(t)}{t} = 0 \quad \text{a.s.}
\]

Therefore, we get (18). This finishes the proof. \(\square\)

### 3.1 Extinction

The main preoccupation in the study of dynamical behavior of epidemic models is how to control the disease dynamics in order to die out in long term. In this section, we shall establish sufficient conditions for extinction of the disease in the stochastic model (3). In the sequel, we set

\[
\langle f(t) \rangle = \frac{1}{t} \int_0^t f(u) du,
\]

and we will investigate the behavior of the stochastic epidemic model (3) according to a following stochastic threshold

\[
R_s = R_0 - \frac{\sigma_2^2}{2(\mu + \alpha_1 + \delta + \gamma)}. \tag{21}
\]

**Theorem 2** Let \((S(t), I(t), Q(t))\) be a solution of system (3) with any initial value \(S(\xi_1) \geq 0, I(\xi_1) \geq 0\) and \(Q(\xi_1) \geq 0\) for all \(\xi_1 \in [-\tau_1, 0), \xi_2 \in [-\tau_2, 0)\) and \(\xi_3 \in [-\tau_3, 0)\) with \(S(0) > 0, I(0) > 0\) and \(Q(0) > 0\). If \(R_s < 1\) then

\[
\lim_{t \to \infty} \frac{\log(I(t))}{t} \leq (\mu + \alpha_1 + \delta + \gamma)(R_s - 1) < 0, \quad \text{a.s.} \tag{22}
\]

Moreover,

\[
\lim_{t \to \infty} \langle S(t) \rangle = \frac{A}{\mu + p(1 - e^{-\mu \tau_2})} \quad \text{a.s} \tag{23}
\]

and

\[
\lim_{t \to \infty} \langle Q(t) \rangle = 0 \quad \text{a.s.} \tag{24}
\]

**Proof** We have

\[
d(S(t) + I(t) + \frac{e^{-\mu \tau_1}}{\mu + \alpha_2 + \varepsilon} Q(t) + pe^{-\mu \tau_1} \int_{t-\tau_1}^t S(s) ds + \gamma e^{-\mu \tau_2} \int_{t-\tau_2}^t I(s) ds + \varepsilon e^{-\mu \tau_3} \int_{t-\tau_3}^t Q(s) ds) = \left[ A - (\mu + p(1 - e^{-\mu \tau_1}) S(t) - (\mu + \alpha_1 + \gamma(1 - e^{-\mu \tau_2}) + \delta - \frac{\delta \varepsilon e^{-\mu \tau_3}}{\mu + \alpha_2 + \varepsilon}) I(t) \right] dt + \sigma_1 S(t) dB_1(t) + \sigma_2 I(t) dB_2(t) + \frac{\varepsilon e^{-\mu \tau_3}}{\mu + \alpha_2 + \varepsilon} Q(t) dB_3(t)
\]

\(\square\) Springer
\[- \frac{(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta)(\mu + \alpha_2) + \varepsilon(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta(1 - e^{-\mu T}))}{\mu + \alpha_2 + \varepsilon} I(t) dt. \quad (25)\]

Then, we can get

\[
S(t) + I(t) + \frac{e^{x(t)}}{\mu + \alpha_2 + \varepsilon} Q(t) + pe^{-\mu t} \int_{t-\tau_1}^t S(s)ds + ye^{-\mu t} \int_{t-\tau_2}^{t-\tau_1} I(s)ds + e(e^{-\mu t}) \int_{t-\tau_3}^{t-\tau_2} Q(s)ds
\]

\[
- \frac{S(0) + I(0) + \int_{t-\tau_1}^t S(s)ds + ye^{-\mu t} \int_{t-\tau_2}^{t-\tau_1} I(s)ds + e(e^{-\mu t}) \int_{t-\tau_3}^{t-\tau_2} Q(s)ds}{(\mu + p(1 - e^{-\mu t}))t}
\]

\[
= A - \left(\frac{(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta)(\mu + \alpha_2) + \varepsilon(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta(1 - e^{-\mu T}))}{\mu + \alpha_2 + \varepsilon}\right) \langle I(t) \rangle.
\]

Thus

\[
\langle S(t) \rangle = A - \left(\frac{(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta)(\mu + \alpha_2) + \varepsilon(\mu + \alpha_1 + \gamma(1 - e^{-\mu t}) + \delta(1 - e^{-\mu T}))}{\mu + \alpha_2 + \varepsilon}\right) \langle I(t) \rangle - \phi(t), \quad (26)
\]

where

\[
\phi(t) = \frac{S(t) + I(t) + \int_{t-\tau_1}^t S(s)ds + ye^{-\mu t} \int_{t-\tau_2}^{t-\tau_1} I(s)ds + e(e^{-\mu t}) \int_{t-\tau_3}^{t-\tau_2} Q(s)ds}{(\mu + p(1 - e^{-\mu t}))t}
\]

\[
- \frac{S(0) + I(0) + \int_{t-\tau_1}^t S(s)ds + ye^{-\mu t} \int_{t-\tau_2}^{t-\tau_1} I(s)ds + e(e^{-\mu t}) \int_{t-\tau_3}^{t-\tau_2} Q(s)ds}{(\mu + p(1 - e^{-\mu t}))t}
\]

\[
+ \frac{1}{(\mu + p(1 - e^{-\mu t}))t} \left(\frac{\sigma_1}{t} S(t)dB_1(t) + \frac{\sigma_2}{t} I(t)dB_2(t) + \frac{\sigma_3 e^{-\mu t}}{t} Q(t)dB_3(t)\right).
\]

(27)

From the strong law of large numbers and lemma 2, we have

\[
\lim_{t \to \infty} \phi(t) = 0 \quad \text{a.s.} \quad (28)
\]

Applying Itô’s formula, we get

\[
d \log(I(t)) = \left[\beta S(t) - \left(\mu + \alpha_1 + \delta + \gamma + \frac{\sigma_2^2}{2}\right)\right] dt + \sigma_2 dB_2(t). \quad (29)
\]

From (26) and (29) we get

\[
\frac{\log I(t)}{t} \leq \frac{\beta A}{\mu + p(1 - e^{-\mu t})} - \left(\mu + \alpha_1 + \delta + \gamma + \frac{\sigma_2^2}{2}\right) - \beta \phi(t) + \frac{\sigma_2 B_2(t)}{t} + \frac{\log(I(0))}{t}.
\]

Springer
By the law of large number for martingales [21] and (28), it follows that for $R_s < 1$, we obtain

$$\limsup_{t \to \infty} \frac{\log I(t)}{t} \leq (\mu + \gamma + \delta)(R_s - 1) < 0 \text{ a.s.}$$

which leads to

$$\lim_{t \to \infty} I(t) = 0 \text{ a.s.} \quad (30)$$

From (26)

$$\lim_{t \to \infty} \langle S(t) \rangle = \frac{A}{\mu + p(1 - e^{-\mu t})} \left( \frac{\mu + \alpha_1 + \gamma(1 - e^{-\mu_2 t}) + \delta(1 - e^{-\mu_3 t})}{(\mu + \alpha_2 + \gamma)(\mu + p(1 - e^{-\mu t}))} \right) \lim_{t \to \infty} \langle I(t) \rangle$$

From the third equation of the system, it follows that

$$\frac{Q(t) - Q(0)}{t} = \delta \langle I(t) \rangle - (\mu + \alpha_2 + \epsilon) \langle Q(t) \rangle + \frac{\sigma_3}{t} \int_0^t Q(s) dB_3(s).$$

Thus, it follows from Lemma 2 and (30) that

$$\lim_{t \to \infty} \langle Q(t) \rangle = 0 \text{ a.s.}$$

This finishes the proof. □

3.2 Persistence in mean

In this section, to study the persistence of the disease, we will establish sufficient conditions to fulfill the conditions in the definition of persistence in mean in [14], we also need the following lemma presented in [14].

Lemma 3 Let $g \in C([0, \infty) \times \Omega, (0, \infty))$ and $G \in C([0, \infty) \times \Omega, \mathbb{R})$ such that

$$\lim_{t \to \infty} \frac{G(t)}{t} = 0 \text{ a.s.}$$

If for all $t \geq 0$

$$\ln g(t) \geq \lambda_0 t - \lambda \int_0^t g(s) ds + G(t) \text{ a.s.}$$

Then

$$\liminf_{t \to \infty} (g(t)) \geq \frac{\lambda_0}{\lambda} \text{ a.s.,}$$

where $\lambda_0 \geq 0$ and $\lambda > 0$ are two real numbers.
Theorem 3 Let \((S(t), I(t), Q(t))\) be the solution of system (3) with any initial value \(S(ξ_1) ≥ 0, I(ξ_1) ≥ 0\) and \(Q(ξ_1) ≥ 0\) for all \(ξ_1 ∈ [−τ_1, 0)\), \(ξ_2 ∈ [−τ_2, 0)\) and \(ξ_3 ∈ [−τ_3, 0)\) with \(S(0) > 0, I(0) > 0\) and \(Q(0) > 0\). If \(R_s > 1\) then

\[
\liminf_{t→∞} \langle I(t) \rangle = I^* > 0,
\]

where

\[
I^* = \frac{(μ + α_2 + ε)(μ + p(1 − e^{−μτ_1}))(μ + α_1 + γ + δ)(R_s − 1)}{β[(μ + α_1 + γ(1 − e^{−μτ_2}) + δ(μ + α_2) + ε(μ + α_1 + γ(1 − e^{−μτ_2}) + δ(1 − e^{−μτ_3}))]]},
\]

\[
\limsup_{t→∞} \langle S(t) \rangle = \frac{μ + α_1 + γ + δ + \frac{σ_2^2}{2}}{β}
\]

and

\[
\liminf_{t→∞} \langle Q(t) \rangle = \frac{δ I^*}{(μ + α_2 + ε)} > 0.
\]

Proof It follows from (26) and (29) that

\[
\log I(t) = \left(\frac{βA}{μ + p(1 − e^{−μτ_1})} − \left(μ + α_1 + γ + δ + \frac{σ_2^2}{2}\right)\right)t
\]

\[
− β[(μ + α_1 + γ(1 − e^{−μτ_2}) + δ(μ + α_2) + ε(μ + α_1 + γ(1 − e^{−μτ_2}) + δ(1 − e^{−μτ_3})))] \langle I(t) \rangle t
\]

\[
+ σ_2 B_2(t) + \log I(0) − β t φ(t).
\]

Therefore, from (28) and lemma 3, we get

\[
\liminf_{t→∞} \langle I(t) \rangle = I^*.
\]

(31)

Thus

\[
\limsup_{t→∞} \langle S(t) \rangle = \frac{μ + α_1 + γ + δ + \frac{σ_2^2}{2}}{β} \text{ a.s.}
\]

From the third equation of the system, we get

\[
\frac{Q(t) − Q(0)}{t} = δ \langle I(t) \rangle − (μ + α_2 + ε) \langle Q(t) \rangle + \frac{σ_3}{t} \int_0^t Q(s) dB_3(s).
\]

(32)

By the virtue of lemma 2 and (31)

\[
\liminf_{t→∞} \langle Q(t) \rangle = \frac{δ}{μ + α_2 + ε} \liminf_{t→∞} \langle I(t) \rangle
\]

\[
= \frac{δ I^*}{(μ + α_2 + ε)} \text{ a.s.}
\]
Therefore the conditions in the definition of persistence in mean [14] are verified. This completes the proof.

4 The existence of stationary distribution

The ergodicity is one of the most important proprieties which will result that the infectious disease will survive in a population, which means a relatively weak characteristic. In the following, we will give a definition of the stationary distribution of the stochastic delayed systems. Then, we will discuss the existence of stationary distribution and the ergodicity of the delayed stochastic system (3) by constructing a suitable Lyapunov functional and using the stochastic Lyapunov analysis methods.

We recall that for each \( t \geq 0 \) and probability measure \( \mu \) on \((C([-\tau, 0]; \mathbb{R}^d_+), \mathcal{M}[-\tau, 0])\), where \( \mathcal{M}[-\tau, 0] \) is the associated Borel \( \sigma \)-algebra in \([-\tau, 0]\), consider the probability measure \( \mu P_t \) on \((C([-\tau, 0]; \mathbb{R}^d_+), \mathcal{M}[-\tau, 0])\) defined by

\[
(\mu P_t)(\Delta) = \int_{C([-\tau, 0]; \mathbb{R}^d_+)} P_t(x, \Delta) \mu(dx), \quad \text{for} \ \Delta \in \mathcal{M}[-\tau, 0]. \tag{33}
\]

**Definition 1** Stationary Distribution [15]

A stationary distribution for (4) is a probability measure \( \pi \) on \((C([-\tau, 0]; \mathbb{R}^d_+), \mathcal{M}[-\tau, 0])\) such that

\[
(\pi P_t)(\Delta) = \pi(\Delta) \quad \text{for all} \ t \geq 0 \ \text{and} \ \Delta \in \mathcal{M}[-\tau, 0].
\]

**Theorem 4** Let \( \mathcal{R}_s > 1 \), then for any initial conditions (5), stochastic delayed system (3) admits a stationary distribution \( \pi(\cdot) \), and the solution of system (3) is ergodic.

**Proof** The diffusion matrix of the stochastic delayed SIQR model (3)

\[
A(S, I, Q) = \begin{bmatrix}
\sigma^2_1 S^2 & 0 & 0 \\
0 & \sigma^2_2 I^2 & 0 \\
0 & 0 & \sigma^2_3 Q^2
\end{bmatrix}.
\tag{34}
\]

Let \( \Gamma \) be any bounded domain in \( \mathbb{R}^3_+ \), then there exists a positive constant

\[
L_0 = \min\{\sigma^2_1 S^2, \sigma^2_2 I^2, \sigma^2_3 Q^2, (S, I, Q) \in \bar{\Gamma}\}.
\]

such that

\[
\sum_{i,j=1}^3 a_{ij}(S, I, Q)\xi_i\xi_j = \sigma^2_1 S^2\xi_1^2 + \sigma^2_2 I^2\xi_2^2 + \sigma^2_3 Q^2\xi_3^2 \\
\geq L_0|\xi|^2, (S, I, Q) \in \bar{\Gamma}, \xi = (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3.
\]

This leads to verify the first condition, where the smallest eigenvalue of the diffusion matrix \( A(S, I, Q) \) is bounded away from zero.
Next, we construct a $C^2$ function $\tilde{V}(X_t, t)$ with $X_t = (S(t), I(t), Q(t))$ and a closed set $U_\varepsilon \in \mathbb{R}_+^3$ such that $\sup_{X \in \mathbb{R}_+^3 \setminus U_\varepsilon} \mathcal{L}\tilde{V} < -\tilde{M} < 0$, with $\tilde{M}$ is a positive constant and

$$\mu - \frac{m\sigma^2}{2} > 0,$$

(35)

where $m$ is a positive constant.

We define a Lyapunov functional as follows

$$\hat{V}(X_t, t) = M\tilde{V}_1 + \tilde{V}_2 + \tilde{V}_3,$$

(36)

where

$$\tilde{V}_1 = -\left(\log I + \frac{\beta}{u + p(1 - e^{-\mu_1})}\left(S + I + pe^{-\mu_1}\int_{t-\tau_1}^{t} S(s)ds\right)\right),$$

$$\tilde{V}_2 = -\log S - \log Q,$$

$$\tilde{V}_3 = \frac{1}{m + 1}\left(S + I + Q + pe^{-\mu_1}\int_{t-\tau_1}^{t} e^{\mu S(s)}ds + \gamma e^{-\mu_1}\int_{t-\tau_2}^{t} e^{\mu S(s)}I(s)ds +\epsilon e^{-\mu_1}\int_{t-\tau_3}^{t} e^{\mu S(s)}Q(s)ds\right)^{m+1},$$

and $M > 0$ is a constant large enough verifying

$$-\tilde{M}\lambda + D \leq -1,$$

(37)

with the terms $\tilde{\lambda}$ and $D$ defined later.

Moreover, $\hat{V}(X_t, t)$ is a continuous function and have a minimum point $(S_0, I_0, Q_0)$ in the interior of $\mathbb{R}_+^3$. Therefore, Let $\tilde{V} : \mathbb{R}_+^3 \rightarrow \mathbb{R}_+$ be a nonnegative function such that

$$\tilde{V} = \hat{V}(S, I, Q) - \hat{V}(S_0, I_0, Q_0).$$

Applying Itô’s formula on $\tilde{V}_1$, we obtain

$$\mathcal{L}\tilde{V}_1 \leq -\beta S + \left(\mu + \alpha_1 + \gamma + \delta + \frac{\sigma^2}{2}\right)$$

$$- \frac{A\beta}{\mu + p(1 - e^{-\mu_1})} + \beta S + \frac{\beta(\mu + \alpha_1 + \gamma + \delta)}{\mu + p(1 - e^{-\mu_1})} I$$

$$:= - (\mu + \alpha_1 + \gamma + \delta)(\mathcal{R}_x - 1) + \frac{\beta(\mu + \alpha_1 + \gamma + \delta)}{\mu + p(1 - e^{-\mu_1})} I$$

$$:= - \tilde{\lambda} + \frac{\beta(\mu + \alpha_1 + \gamma + \delta)}{\mu + p(1 - e^{-\mu_1})} I,$$
where \( \tilde{\lambda} = (\mu + \alpha_1 + \gamma + \delta)(R_s - 1) > 0 \), Using Itô’s formula on \( \tilde{V}_2 \) and \( \tilde{V}_3 \), we get

\[
\mathcal{L}\tilde{V}_2 = -\frac{A}{S} + \beta I + \left( \mu + p + \frac{\sigma_1^2}{2} \right) - \frac{pS(t - \tau_1)e^{-\mu\tau_1}}{S(t)} - \frac{\gamma I(t - \tau_2)e^{-\mu\tau_2}}{S(t)} - \frac{\epsilon Q(t - \tau_3)e^{-\mu\tau_1}}{S(t)} - \frac{\epsilon I(t)}{Q(t)} + \mu + \alpha_2 + \epsilon + \frac{\sigma_3^2}{2},
\]

\[
\mathcal{L}\tilde{V}_3 = \tilde{V}_3^m (A - \mu(S + I + Q) - \alpha_1 I - \alpha_2 Q - \mu pe^{-\mu t} \int_{t\tau_1}^t e^{\mu s} S(s) ds
- \mu \gamma e^{-\mu t} \int_{t\tau_2}^t e^{\mu s} I(s) ds - \mu \epsilon e^{-\mu t} \int_{t\tau_3}^t e^{\mu s} Q(s) ds
+ \frac{m}{2} \tilde{V}_3^{m-1}(\sigma_1^2 S^2 + \sigma_2^2 I^2 + \sigma_3^2 Q^2)
\leq \tilde{V}_3^m (A - \mu \tilde{V}_3) + \frac{m\sigma_2^2}{2} \tilde{V}_3^{m+1}
\leq B - \frac{1}{2} \left( \mu - \frac{m\sigma_2^2}{2} \right) (S^{m+1} + I^{m+1} + Q^{m+1}),
\]

where

\[
B = \sup_{(S, I, Q) \in \mathbb{R}^+_3} \left\{ A\tilde{V}_1 - \frac{1}{2} \left( \mu - \frac{m\sigma_2^2}{2} \right) \tilde{V}_1^{m+1} - \frac{1}{2} \left( \mu - \frac{m\sigma_2^2}{2} \right) \left( pe^{-\mu t} \int_{t\tau_1}^t e^{-\mu s} S(s) ds + \gamma e^{-\mu t} \int_{t\tau_2}^t e^{-\mu s} I(s) ds + \epsilon e^{-\mu t} \int_{t\tau_3}^t e^{-\mu s} Q(s) ds \right) \right\}.
\]

Hence

\[
\mathcal{L}\tilde{V} \leq -M\tilde{\lambda} + \frac{MB(\mu + \alpha_1 + \delta + \gamma)}{\mu + p(1 - e^{-\mu\tau_1})} I - \frac{A}{S} - \frac{\delta I(t)}{Q(t)} + B + \beta I + 2\mu + \alpha_2 + \epsilon + \frac{\sigma_1^2 + \sigma_3^2}{2} - \frac{1}{2} \left( \mu - \frac{m\sigma_2^2}{2} \right) (S^{m+1} + I^{m+1} + Q^{m+1}).
\]

Define a bounded set such that

\[
U_\epsilon = \left\{ (S, I, Q) \in \mathbb{R}^3_+, \epsilon \leq S \leq \frac{1}{\epsilon}, \epsilon^2 \leq I \leq \frac{1}{\epsilon}, \epsilon^3 \leq Q \leq \frac{1}{\epsilon^3} \right\},
\]

where \( 0 < \epsilon < 1 \) is a sufficiently small and such that

\[
-\frac{\min(A, \gamma)}{\epsilon} + D < -1,
\]

\( \triangledown \) Springer
\[-\frac{1}{4} \left[ \mu - m \sigma^2 \right] e^{m+1} + E < -1, \tag{42} \]
\[-\frac{1}{4} \left[ \mu - m \sigma^2 \right] e^{m+1} + F < -1, \tag{43} \]
\[-\frac{1}{4} \left[ \mu - m \sigma^2 \right] e^{m+1} + G < -1, \tag{44} \]

with \( D, E, F \) and \( G \) are positive constants, where the expressions are introduced after in the presented cases. Knowing that for a sufficiently small \( \varepsilon \). We divide \( \mathbb{R}^3_+ \setminus U_\varepsilon \) into six domains, such that

\[
U_1 = \{(S, I, Q) \in \mathbb{R}^3_+, 0 < S < \varepsilon\}, \quad U_2 = \{(S, I, Q) \in \mathbb{R}^3_+, 0 < I < \varepsilon\}, \\
U_3 = \{(S, I, Q) \in \mathbb{R}^3_+, \varepsilon^2 < I, 0 < Q < \varepsilon^3\}, \\
U_4 = \{(S, I, Q) \in \mathbb{R}^3_+, S > \frac{1}{\varepsilon}\}, \quad U_5 = \{(S, I, Q) \in \mathbb{R}^3_+, I > \frac{1}{\varepsilon}\}, \\
U_6 = \{(S, I, Q) \in \mathbb{R}^3_+, Q > \frac{1}{\varepsilon^3}\}. 
\]

In the following, we should prove that \( \mathcal{L} \tilde{V} \leq -1 \) on \( \mathbb{R}^3_+ \setminus U_\varepsilon \), it means verifying it on the above six domains.

**Case 1** If \((S, I, Q) \in U_1\), then

\[
\mathcal{L} \tilde{V} \leq -{\frac {A}{S}} + M \frac {\beta (\mu + \alpha_1 + \alpha + \gamma)}{\mu + p (1 - e^{-\mu \tau_1})} I - \frac{1}{2} \left[ \mu - \frac{m \sigma^2}{2} \right] (S^{m+1} + I^{m+1} + Q^{m+1}) + B \\
+ \beta I + 2 \mu + p + \alpha_2 + \varepsilon \frac{\sigma_I^2 + \sigma_Q^2}{2} \\
\leq -\frac{A}{\varepsilon} + D, \tag{45} \]

where

\[
D = \sup_{(S, I, Q) \in \mathbb{R}^3_+} \left\{ \frac{M \beta (\mu + \alpha_1 + \delta + \gamma)}{\mu + p (1 - e^{-\mu \tau_1})} I - \frac{1}{2} \left[ \mu - \frac{m \sigma^2}{2} \right] (S^{m+1} + I^{m+1} + Q^{m+1}) + \beta I + B + 2 \mu + p + \alpha_2 + \varepsilon + \frac{\sigma_I^2 + \sigma_Q^2}{2} \right\}. \tag{46} \]

According to (41), one can get that for a sufficiently small \( \varepsilon \)

\[
\mathcal{L} \tilde{V} \leq -1 \quad \text{for any } (S, I, Q) \in U_1. \tag{47} \]
Case 2 If \((S, I, Q) \in U_2\), we get
\[
\mathcal{L} \tilde{V} \leq -M\lambda + M \frac{\beta(\mu + \alpha_1 + \alpha + \gamma)}{\mu + p(1 - e^{-\mu t_1})} I - \frac{1}{2} \left[ \mu - \frac{m\sigma^2}{2} \right] (S^{m+1} + I^{m+1} + Q^{m+1}) \\
+ B + \beta I + 2\mu + p + \alpha_2 + \epsilon + \frac{\sigma_1^2 + \sigma_3^2}{2}
\]
\[
\leq -M\tilde{\lambda} + D.
\]

According to (37), one can get that for a sufficiently small \(\epsilon\)
\[
\mathcal{L} \tilde{V} \leq -1 \quad \text{for any} \ (S, I, Q) \in U_2.
\]

Case 3 When \((S, I, Q) \in U_3\), it follows that
\[
\mathcal{L} \tilde{V} \leq -\frac{\delta I}{Q} + M \frac{\beta(\mu + \alpha_1 + \delta + \gamma)}{\mu + p(1 - e^{-\mu t_1})} I - \frac{1}{2} \left[ \mu - \frac{m\sigma^2}{2} \right] (S^{m+1} + I^{m+1} + Q^{m+1}) \\
+ \beta I + B + 2\mu + p + \alpha_2 + \epsilon + \frac{\sigma_1^2 + \sigma_3^2}{2}
\]
\[
\leq -\frac{\delta}{\epsilon} + D.
\]

By (41), we conclude that \(\mathcal{L} \tilde{V} \leq -1\) on \(U_3\)

Case 4 When \((S, I, Q) \in U_4\), we get
\[
\mathcal{L} \tilde{V} \leq -\frac{1}{4} \left[ \mu - \frac{m\sigma^2}{2} \right] S^{m+1} + E
\]
\[
\leq -\frac{1}{4} \left[ \mu - \frac{m\sigma^2}{2} \right] I^{m+1} + E,
\]

where
\[
E = \sup_{(S,I,Q) \in \mathbb{R}^3_+} \left\{ -\frac{1}{4} \left[ \mu - \frac{m\sigma^2}{2} \right] S^{m+1} + \frac{M \beta(\mu + \alpha_1 + \delta + \gamma)}{\mu + p(1 - e^{-\mu t_1})} I + \beta I \\
+ B + 2\mu + p + \alpha_2 + \epsilon - \frac{1}{2} \left[ \mu - \frac{m\sigma^2}{2} \right] (I^{m+1} + Q^{m+1}) + \frac{\sigma_1^2 + \sigma_3^2}{2} \right\}.
\]

By virtue of (42), we get that \(\mathcal{L} \tilde{V} \leq -1\) for all \((S, I, Q) \in U_4\)

Case 5 When \((S, I, Q) \in U_5\), we get
\[
\mathcal{L} \tilde{V} \leq -\frac{1}{4} \left[ \mu - \frac{m\sigma^2}{2} \right] I^{m+1} + F
\[ L \tilde{V} \leq -\frac{1}{4} \left[ \mu - \frac{m \sigma^2}{2} \right] \epsilon^{m+1} + F, \]  

(53)

where

\[
F = \sup_{(S, I, Q) \in \mathbb{R}^3_+} \left\{ -\frac{1}{4} \left[ \mu - \frac{m \sigma^2}{2} \right] I^{m+1} + \frac{M \beta (\mu + \alpha_1 + \delta + \gamma)}{\mu + p(1 - e^{-\mu \tau_1})} I + \beta I \\
+ B + 2\mu + p + \alpha_2 + \epsilon - \frac{1}{2} \left[ \mu - \frac{m \sigma^2}{2} \right] (S^{m+1} + Q^{m+1}) + \frac{\sigma^2_1 + \sigma^2_3}{2} \right\}. 
\]  

(54)

By virtue of (43), we get that \( L \tilde{V} \leq -1 \) for all \((S, I, Q) \in U_5\).

**Case 6** When \((S, I, Q) \in U_6\), we get

\[
L \tilde{V} \leq -\frac{1}{4} \left[ \mu - \frac{m \sigma^2}{2} \right] Q^{m+1} + F \\
\leq -\frac{1}{4} \left[ \mu - \frac{m \sigma^2}{2} \right] \epsilon^{3m+3} + F, 
\]  

(55)

where

\[
F = \sup_{(S, I, Q) \in \mathbb{R}^3_+} \left\{ -\frac{1}{4} \left[ \mu - \frac{m \sigma^2}{2} \right] Q^{m+1} + \frac{M \beta (\mu + \alpha_1 + \delta + \gamma)}{\mu + p(1 - e^{-\mu \tau_1})} I + \beta I \\
+ B + 2\mu + p + \alpha_2 + \epsilon - \frac{1}{2} \left[ \mu - \frac{m \sigma^2}{2} \right] (S^{m+1} + Q^{m+1}) + \frac{\sigma^2_1 + \sigma^2_3}{2} \right\}. 
\]  

(56)

It follows from (44), we get that \( L \tilde{V} \leq -1 \) for all \((S, I, Q) \in U_6\). Hence, from (45), (48), (50), (51), (53) and (55), we get that for a sufficiently small \( \epsilon \)

\[
L \tilde{V} (S, I, Q) \leq -1 \quad \text{for all } (S, I, Q) \in \mathbb{R}^3_+ \setminus U_\epsilon. 
\]

This means that if the solution \((S, I, Q) \in \mathbb{R}^3_+ \setminus U_\epsilon\) of the delayed stochastic epidemic model (3), the mean time \( \tau_x \) at which a path issuing from \( X_t \) reaches the set \( U \) is finite, and \( \sup_{X \in K} E^x \tau < \infty \) for every compact \( K \subset \mathbb{R}^3_+ \).

In addition, Theorem 1 shows that the stochastic epidemic model has a unique global positive solution and by the vertue of Theorem 3.9 in [21]. The solution of the stochastic delayed system (3) is bounded. Therefore, according to [15], these properties imply that Theorem 2.2.1 is verified. Hence, we can obtain that the delayed stochastic system (3) is ergodic and admits a unique stationary distribution. \( \square \)
5 Numerical simulations

In order to simulate our theoretical results for Theorems 2 and 3, we illustrate the paths of the delayed deterministic epidemic model (1) and delayed stochastic epidemic model (3) using the Euler–Maruyama method to investigate numerically the results on the stochastic threshold \( R_s \).

**Example 1** In this simulated example, choosing the initial value \((S(0), I(0), Q(0)) = (5, 15, 5)\), and the parameters values are \( A = 1, \mu = 0.09, \beta = 0.18, \gamma = 0.55, \delta = 0.44, \varepsilon = 0.6, p = 0.2, \sigma_1 = 0.2, \sigma_2 = 0.85, \sigma_3 = 0.5, \alpha_1 = 0.4, \alpha_2 = 0.02, \) and \( \tau_1 = \tau_2 = \tau_3 = 0.5 \). We can calculate easily the basic reproduction rate \( R_0 = 1.2309 \) and the stochastic threshold \( R_s = 0.9868 < 1 \). According to Theorem 2 the disease will go to extinction. In Fig. 1, the extinction of the disease is well observed in the illustration of the delayed stochastic system trajectories.

**Example 2** In this simulated example, choosing the initial value \((S(0), I(0), Q(0)) = (10, 0.1, 0.1)\), we keep the same parameters as Example 1 and we change \( \mu = 0.09, \beta = 0.39, \gamma = 0.55, \sigma_2 = \sigma_3 = 0.4 \). We alleviate the quarantine strategy by reducing the quarantined individuals rate to \( \varepsilon = 0.3 \). We can calculate easily the basic reproduction rate \( R_0 = 2.9679 \) and the stochastic threshold \( R_s = 2.9077 > 1 \). As observed in Fig. 2 the disease will persist in mean which support the conclusion of Theorem 3.

6 Conclusion

Since the quarantine has proven significant results in the control of the infectious diseases in a population such as the case of the recent pandemic COVID19 case. Therefore, we investigated in this work the behaviour of a delayed stochastic epidemic model with isolation, vaccination, elimination, temporary immunity.

In fact, we have studied the dynamics of a SIQR epidemic model including the notion of delay to describe the time efficiency of vaccine proposed in [9], the temporary loss of immunity [1] and the temporary loss of immunity after a quarantine is illustrated using the delay for quarantined individuals. We present a stochastic threshold $R_s$ which is used to establish a sufficient condition for the extinction, persistence in mean and the existence of stationary distribution.
