We present an improved protocol for entanglement purification of bipartite mixed states. The protocol requires two-way classical communication and hence implies an improved lower bound on the quantum capacity with two-way classical communication of the quantum depolarizing channel.

1 Introduction
Quantum information theory and quantum computation study the use of quantum physics in information processing and computation[1]. Many important results such as quantum teleportation, superdense coding, factoring and search algorithms make use of quantum entanglements as fundamental resources [2, 3, 4, 5]. Therefore, entanglement purification protocols, the procedures by which we extract pure-state entanglements from mixed states, merit our study.

In this work, we follow the framework of [6, 7] and present a new purification protocol with improved yields.

1.1 Notation
We denote von Neumann entropy by $S(\rho)$ and Shannon entropy by $H(p_0, p_1, \ldots)$. The following notation is used for the four Bell states:

---

*E-mail address: leung@math.mit.edu*  
*E-mail address: shor@math.mit.edu*
To facilitate our discussion later on, we also use two classical bits to label each of the Bell states:

\[
\begin{align*}
\Phi^+ &= 00 \\
\Psi^+ &= 01 \\
\Phi^- &= 10 \\
\Psi^- &= 11
\end{align*}
\]  

and we concentrate on the generalization of the Werner state \[8\]:

\[
\rho_F = F |\Phi^+ \rangle \langle \Phi^+| + \frac{1-F}{3} \left( |\Phi^- \rangle \langle \Phi^-| + |\Psi^+ \rangle \langle \Psi^+| + |\Psi^- \rangle \langle \Psi^-| \right) \tag{3}
\]

This work concerns entanglement purification protocols. At the beginning of these protocols, two persons, Alice and Bob, share a large number of quantum states \(\rho_F\), say \(\rho_F^\otimes n\), and they are allowed to communicate classically, apply unitary transformations and perform projective measurements. We place no restriction on the size of their ancilla systems so that we lost no generality in restricting their local operations to unitaries and projective measurements. In the end, the quantum states \(\Upsilon\) shared by Alice and Bob are to be a close approximation of the maximally entangled states \(|\Phi^+ \rangle \langle \Phi^+| \otimes m\), or more precisely we require the fidelity between \(\Upsilon\) and \(|\Phi^+ \rangle \langle \Phi^+| \otimes m\) approaches one as \(n\) goes to infinity. We define the yield of such protocols to be \(m/n\).

1.2 Previous protocols

We briefly review some previous protocols in the following subsections:

1.2.1 Universal hashing

Universal hashing was introduced in [6] and requires only one-way classical communication. The scenario is the same as what was described in section 1.1. The hashing method works by having Alice and Bob each perform some local unitary operations on the corresponding members of the shared bipartite quantum states. They then locally measure some of the pairs to gain information about the Bell states of the remaining unmeasured pairs. It was shown that each measurement can be made to reveal almost 1 bit of information about the
unmeasured pairs; therefore, by measuring \( nS(\rho_F) \) pairs, Alice and Bob can figure out the identities of the remaining unmeasured pairs with high probability. Once the identities of the Bell states are known, Alice and Bob can convert them into the standard states \( \Phi^\pm \) easily. This protocol distills a yield \( D_H = \frac{n - nS(\rho_F)}{n} = 1 - S(\rho_F) \).

### 1.2.2 The recurrence method

![Fig. 1. The recurrence method.](image)

The recurrence method\[^{[6, 9]}\] is illustrated in fig. 1 Alice and Bob put the quantum states \( \rho_F^\otimes n \) into groups of two and apply XOR operations to the corresponding members of the quantum states \( \rho_F^\otimes 2 \), one as the source and one as the target. They then take projective measurements on the target states along the z-axis, and compare their measurement results with the side classical communication channel. If they get identical results, the source pair “passed”; otherwise the source pair “failed”. Alice and Bob then collect all the “passed” pairs, and apply a unilateral \( \pi \) rotation \( \sigma_x \) followed by a bilateral \( \pi/2 \) rotation \( B_x \). This process is iterated until it becomes more beneficial to pass on to the universal hashing. If we denote the quantum states by

\[
\rho = p_{00} |\Phi^+\rangle \langle \Phi^+| + p_{01} |\Psi^+\rangle \langle \Psi^+| + p_{10} |\Phi^-\rangle \langle \Phi^-| + p_{11} |\Psi^-\rangle \langle \Psi^-|,
\]

then this protocol has the following recurrence relation:

\[
\begin{align*}
p'_{00} &= \frac{p^2_{00} + p^2_{10}}{p_{\text{pass}}}; \\
p'_{01} &= \frac{p^2_{01} + p^2_{11}}{p_{\text{pass}}}; \\
p'_{10} &= 2p_{01}p_{11}/p_{\text{pass}}; \\
p'_{11} &= 2p_{00}p_{10}/p_{\text{pass}};
\end{align*}
\]

and

\[
p_{\text{pass}} = p^2_{00} + p^2_{01} + p^2_{10} + p^2_{11} + 2p_{00}p_{10} + 2p_{01}p_{11}
\]

\[^{a}\text{As mentioned in [6], the application of a } \sigma_x \text{ and } B_x \text{ rather than a twirl was proposed by C. Macchiavello.}\]
1.2.3 The Maneva-Smolin method

The Maneva-Smolin method\cite{maneva} is illustrated in fig.2. Alice and Bob first choose a block size $m$ and put the quantum states into groups of $m$. They then apply bipartite XOR gates between each of the first $m - 1$ pairs and the $m$th pairs. After that, they take measurements on these $m$th pairs along the $z$-axis, and compare their results with side classical communication channel. If they get identical results, they perform universal hashing on the corresponding $m - 1$ remaining pairs; if they get different results, they throw away all $m$ pairs. The yield for this method is:

$$p_{\text{pass}} = \frac{m - 1}{m} \left( 1 - \frac{H(\text{passed source states})}{m - 1} \right)$$

![Fig. 2. The Maneva-Smolin method when $m = 4$.](image)

2 Entanglement purification protocol

In section 2.1, we will present our new entanglement purification protocol and compare its yield with the yields obtained by the recurrence method \cite{recurrence} and the Maneva-Smolin method \cite{maneva}. In section 2.2, we will give a closed-form expression for the yield of this new protocol.

2.1 New protocol and improved yield

Our protocol is illustrated in fig.3. Alice and Bob share the quantum states $\rho_F^{\otimes m}$ and put them into groups of four. They then apply the quantum circuit shown in fig.3 and take measurements on the third and fourth pairs along the $x$- and $z$-axis respectively. Using the side classical communication channel, they can compare their results with each other. If they get identical results on both measurements, they keep the first and second pairs and apply universal hashing\cite{universal}. If either of the two results disagrees, they throw away all four pairs.

The four pairs can be described by an 8-bit binary string, and since these are mixed states they are in fact probability distribution over all $256 (= 2^8)$ possible 8-bit binary strings.
Fig. 3. Alice and Bob put the quantum states $\rho_F^{\otimes n}$ into groups of four, and apply quantum circuits consisting only of XOR gates. They then take measurements on the third pair along the x-axis and the fourth pair along the z-axis. With side classical communication, they compare their results and if both results agree, they apply universal hashing on the first two pairs. If either measurement result disagrees, they throw away all four pairs. The yield of this protocol is plotted on fig. 4.

The quantum circuit consists only of XOR gates and therefore maps the 8-bit binary strings, along with their underlying probability distribution, bijectively to themselves. Let us call these probability distributions $P(a_1a_2b_1b_2c_1c_2d_1d_2)$ and $P'(a_1a_2b_1b_2c_1c_2d_1d_2)$.

Our quantum measurements on the third and fourth pairs are simply looking at the 5th bit (measurement on the third pair along x-axis) and the 8th bit (measurement on the fourth pair along z-axis), where a “0” means Alice and Bob getting identical results and a “1” means their getting opposite results. For example, if the 8-bit binary string is “$a_1a_2b_1b_2c_1c_2d_1d_2 = 00100111$”, which corresponds to the quantum states $\Phi^+\Phi^-\Psi^+\Psi^-$, then Alice and Bob will get identical results on the third pair but opposite results on the fourth. The “pass” probability is $p_{pass} = \sum_{a_1,a_2,b_1,b_2,c_1,c_2,d_1,d_2 \in \{0,1\}} P'(a_1a_2b_1b_20c_1c_2d_1d_2)$ and the post-measurement probability distribution is $Q(a_1a_2b_1b_2) = \sum_{c_2,d_1 \in \{0,1\}} P'(a_1a_2b_1b_20c_2d_1d_2)/p_{pass}$. The yield of this method is:

$$p_{pass} \left(1 - \frac{H(Q(a_1a_2b_1b_2))}{2}\right)$$

where $H(Q(a_1a_2b_1b_2))$ is the Shannon entropy function. Fig. 4 compares the yield of our new method with the recurrence method and the Maneva-Smoline method.

2.2 Closed-form expression

The quantum circuit that Alice and Bob apply to the quantum states $\rho_F^{\otimes 4}$ consists only of XOR gates and therefore maps the 8-bit binary strings bijectively to themselves. We call this bijection $f$:
Fig. 4. The dotted line is the yield for modified recurrence method [6]; the dash line is for the Maneva-Smolin method [7]. The yield of our new method is represented by the solid line, and there is an improvement over the previous methods when the initial fidelity is between 7.5 and 8.45.
\[ f : \{0, 1\}^8 \rightarrow \{0, 1\}^8 \\
(a_1, a_2, b_1, b_2, c_1, c_2, d_1, d_2) \mapsto (a_1 \oplus d_1, a_2 \oplus c_2, b_1 \oplus d_1, b_2 \oplus c_2, \\
a_1 \oplus b_1 \oplus c_1 \oplus d_1, c_2, d_1, a_2 \oplus b_2 \oplus c_2 \oplus d_2) \]

In table 1, we list the quantum states that lead to identical measurement results for Alice and Bob and their probabilities in the ensemble \(\rho_F \otimes 4\). Therefore, we can write down expressions for the terms \(p_{\text{pass}}\) and \(H(Q(a_1 a_2 b_1 b_2))\) in equation (4) as follows:

\[
p_{\text{pass}} = F^4 + 18F^2G^2 + 24FG^3 + 21G^4 \\
H(Q(a_1 a_2 b_1 b_2)) = -\left(\frac{F^4 + 3G^4}{p_{\text{pass}}}\right) \log_2 \left(\frac{F^4 + 3G^4}{p_{\text{pass}}}\right) - 9\left(\frac{2F^2G^2 + 2G^4}{p_{\text{pass}}}\right) \log_2 \left(\frac{2F^2G^2 + 2G^4}{p_{\text{pass}}}\right) \\
-6\left(\frac{4FG^3}{p_{\text{pass}}}\right) \log_2 \left(\frac{4FG^3}{p_{\text{pass}}}\right)
\]

where \(G = (1 - F)/3\).

3 Conclusions

We presented a new protocol for entanglement purification assisted by two-way classical communication. It was shown in [6] that such a protocol corresponds to quantum capacity assisted by two-way classical communication of the quantum depolarizing channel, and hence we have a new lower bound for this capacity. In section 2.1, we applied the new protocol to the quantum states

\[
\rho_F = F |\Phi^+\rangle \langle \Phi^+| + \frac{1 - F}{3} \left(|\Phi^-\rangle \langle \Phi^-| + |\Psi^+\rangle \langle \Psi^+| + |\Psi^-\rangle \langle \Psi^-|\right);
\]

however, our method also works for any Bell-diagonal quantum states

\[
\rho = p_{00} |\Phi^+\rangle \langle \Phi^+| + p_{01} |\Psi^+\rangle \langle \Psi^+| + p_{10} |\Phi^-\rangle \langle \Phi^-| + p_{11} |\Psi^-\rangle \langle \Psi^-|.
\]

Equation (5) and (6) then become
\[ p_{\text{pass}} = (p^4_{00} + p^4_{01} + p^4_{10} + p^4_{11}) + 6 \times 4p_{00}p_{01}p_{10}p_{11} + 3 \times \sum_{i,j \in \{0,1\}^2} 2p^2_i p^2_j \]

\[ H(Q(a_1a_2b_1b_2)) = -\left(\frac{p^4_{00} + p^4_{01} + p^4_{10} + p^4_{11}}{p_{\text{pass}}}\right) \log_2 \left(\frac{p^4_{00} + p^4_{01} + p^4_{10} + p^4_{11}}{p_{\text{pass}}}\right) \]

With these equations, we can combine the recurrence method and our new method: we start with the recurrence method and pass on to our new method rather than universal hashing. Indeed, there are improvements, but they occur over segments of narrow regions and the improvements are insignificant. Therefore we believe these improvements have only to do with the number of recurrence steps performed before passing on to universal hashing, and we will spare the readers with the details.

An obvious direction is to look for new protocols with better yields. In particular, as was raised by E.N. Maneva and J.A. Smolin in [7], is there a way to iterate this protocol rather than passing on immediately to universal hashing? It is conceivable that, with such an adaptation, we can have improvements over a wider range of initial fidelity.

After the completion of this work, it came to our attention similar works have been carried out in [10, 11].
