General information

All chemicals were purchased from Sigma-Aldrich and VWR. All chemicals were used as received (exception being 2-(3-bromophenyl)-1,3-dioxolane which was purified by precipitating the aldehyde impurity as its bisulfite adduct). All reactions were performed under an atmosphere of argon using Schlenck techniques. TLC plates (Silica gel 60 F$_{254}$ coated on aluminum plates purchased from Sigma-Aldrich and VWR) were visualized by either UV light (254 nm), Seebach’s stain (superior for THF-derivatives) or KMnO$_4$ solution. Flash column chromatography was performed both manually (using Silica gel 40-63 µm from VWR) and with Büchi Pure C-810 Flash (using Büchi FlashPure EcoFlex cartridges of either 50 µm or 20 µm).

GC-MS(EI) was performed on Agilent 19091S-433 gas chromatograph with an Agilent 5977E MSD detector. Separations were performed on HP-5MS Phenyl Methyl Silox of 30 m x 250 µm x 0.25 µm column.

LC-(HR)MS was performed on a Waters Acquity™ UPLC coupled with a SYNAPT G2-Si Mass Spectrometer using a LockSpray (Zspray™) ESI ionization source.

IR-spectra were recorded on a Bruker FT-IR Spectrometer INVENIO®.

A Büchi® Melting Point B-545 was used to determine the melting points. ¹H-NMR and ¹³C-NMR spectra were recorded on a Varian NMR 400 or Bruker Avance III HD 800 MHz spectrometer. Chemical shifts (δ) are reported in ppm relative to the residual solvent peak. Splitting patterns are indicated as (s) singlet, (d) doublet, (dd) doublet of doublets, (ddd) doublet of doublet of doublets, (dddd) doublet of doublet of doublet of doublets, (t) triplet, (tt) triplet of triplets, (dt) doublet of triplets), (td) triplet of doubles, (ddd) doublet of triplet of doubles, (ddt) doublet of doublet of triplets, (qd) doublet of quartets, (qt) quartet of triplets, (dq) doublet of quartet of doublets, (quint) quintet, (sex) sextet, (hept) heptet, (m) multiplet. Coupling constants (J) are reported in Hertz (Hz).

Photoreactions were conducted in Biotage® Microwave Reaction Vials placed in EvoluChem™ PhotoRedOx Box By HepatoChem equipped with an EvoluChem LED 18 W (P201-18-2, 450-455 nm) as irradiation source and was used without any filter. Emission spectrum can be found at https://www.hepatochem.com/photoreactors-leds-accessories/led-evoluchem.

*Table 2*. 1 mol% of the metal additive and 2-(4-chlorophenyl)tetrahydrofuran (1aa) were used in each reaction and run for 6 hours. All vials and stir bars were carefully cleaned with aqua regia before reaction.

To double-check that Fe(acac)$_3$ and Co(ClO$_4$)$_2$ are active catalysts for the reaction experiments were conducted again for these two metal complexes in brand new vials. In case of Fe(acac)$_3$ the results were always reproducible while for Co(ClO$_4$)$_2$ slightly diminished yields were sometimes obtained. Hence, we concluded that Fe(acac)$_3$ was the most efficient catalyst and continued exploring it in our system.
Synthesis of starting materials

Two general methods have been used to prepare a large portion of the starting materials. The specific syntheses of starting materials beyond these two methods are described in the following section together with the characterization data for that compound.

Method I - THF-derivatives

The corresponding 4-oxo-4-phenylbutyric acid (5 mmol) was added portion wise to a suspension of LiAlH₄ (4 eq.) in Et₂O (50 ml) at 0 °C. Reaction was then stirred at r.t until completed as judged by TLC. Work-up procedure according to the Fieser protocol. Almost quantitative yields of the diols were obtained, and the diols were used in the next step without further purification. The cyclization of the diols to tetrahydrofurans was conducted as described in[1]. No purification on silica was necessary.

Method II – THF, THP and dioxane-derivatives

Cyclic ethers were synthesized according to procedure in[2]. Oven dried Biotage MW vial (20 ml) was charged with the boronic acid (2 mmol), Ni(acac)₂ (10 mol%, 51 mg), PPh₃ (10 mol%, 52 mg), K₃PO₄ (1 eq., 425 mg) and THF (anhydrous, 12 ml). The vial was capped and reaction mixture sparged with argon for 10 min. Then DTBP (1.2 eq., 0.44 ml) was added in one portion and the reaction mixture heated to 100 °C overnight. After cooled to r.t the reaction was diluted with 20 ml HCl(aq) (2M)¹ and extracted 3 times with 20 ml Et₂O, dried over Na₂SO₄ and concentrated under reduced pressure. Products were then purified on silica. Seebach’s stain turned out to be superior in visualizing the product on TLC plates.

Care must be taken regarding reduced pressure since the compounds are, in some cases, volatile. 20 mbar and 40 °C water bath worked fine in most cases, exception being the 2,4-difluoro (compound X).

¹In cases where acid sensitive compounds were used only water was used and turned out to work OK.

Experimental procedure for photoreaction

All reactions were run in duplicate unless otherwise stated. Dichloroethane (DCE, anhydrous) and BrCCl$_3$ were deoxygenated by sparging with argon for 20 min. Cyclic ether or acetal (0.2 mmol), Fe(acac)$_3$ (1 mol%) and a stir bar was added to a Biotage MW vial (10 ml) and capped. Reaction atmosphere was exchanged to argon by “sparging” head space for 10 min. Then BrCCl$_3$ (3 eq. 60 µL) followed by DCE (0.1 M, 2 ml) was added. The capped end of the vial was wrapped with parafilm and then placed in a photoreactor and irradiated with 455 nm light for 18 h at 27 °C (with fan). The two duplicated reactions were combined and adsorbed onto Celite and purified on silica. Isolated yields were thereby obtained as an average.

Compounds on TLC-plates were visualized with UV (254 nm), Seebach’s stain or KMnO$_4$.

Mechanism – Experiments and Calculations

UV-Vis

To test whether Fe(acac)$_3$ and BrCCl$_3$ could form an electron-donor-acceptor complex (EDA complex) UV-Vis were recorded for the two pure substances in DCE as well as their mixtures. A solution of Fe(acac)$_3$ and BrCCl$_3$ in DCE (0.2 mM and 60 mM respectively) was initially measured. BrCCl$_3$ (300 eq. 17.7 µL) was then added to the cuvette and UV-Vis was once more measured (Mixture 1). A second equal portion of BrCCl$_3$ was added to the same cuvette and UV-Vis recorded once more (Mixture 2). In the plot below the concentration has been corrected for the added volume of BrCCl$_3$. As can be seen in Figure S1 below, no shift of the bands has occurred upon mixing Fe(acac)$_3$ and BrCCl$_3$ and no new charge-transfer bands can be seen. The only difference is a slight decrease in absorbance for Mixture 1 and Mixture 2, which correlates with the slightly diluted solution by the added volume of BrCCl$_3$.

Figure S1. UV-vis absorbance spectroscopy experiments on mixture. No shifts of bands was observed indicating there is no formation of an EDA-complex.
Reactions

Reactions in this section refers to those in Scheme 5 and Scheme 6. All reaction were prepared as described in Experimental procedure for photoreaction and conducted at 0.1 mmol scale with respect to 1aa.

Experiment i): 1aa, 1 eq. Fe(acac)₃ and no BrCCl₃ in DCE, irradiated for 6 h. These conditions did not provide any product.

Experiment ii): 1aa, 3 eq. methyl acrylate, 1 eq. Fe(acac)₃ and no BrCCl₃ in DCE, irradiated for 6 h. These conditions did not provide any product.

Experiment iii): 1aa, 1 eq. NBu₄Br, 1 eq. Fe(acac)₃ and no BrCCl₃ irradiated for 6h. These conditions did not provide any product.

Experiment iv): 0.1 mmol Fe(acac)₃ and 1 eq. BrCCl₃ was dissolved in 0.5 ml DCE and irradiated for 6 h. These conditions afforded hexachloroethane as detected my GC-MS(EI).

Experiment v): 1aa, 1 eq. TEMPO, 1 eq. Fe(acac)₃, 3 eq. BrCCl₃ in DCE, irradiated for 6h. These conditions did not provide any product.
