ON THE REPRESENTATION OF POLYHEDRA BY POLYNOMIAL INEQUALITIES

MARTIN GRÖTSCHEL AND MARTIN HENK

Abstract. A beautiful result of Bröcker and Scheiderer on the stability index of basic closed semi-algebraic sets implies, as a very special case, that every $d$-dimensional polyhedron admits a representation as the set of solutions of at most $d(d+1)/2$ polynomial inequalities. Even in this polyhedral case, however, no constructive proof is known, even if the quadratic upper bound is replaced by any bound depending only on the dimension.

Here we give, for simple polytopes, an explicit construction of polynomials describing such a polytope. The number of used polynomials is exponential in the dimension, but in the 2- and 3-dimensional case we get the expected number $d(d+1)/2$.

1. Introduction

By a surprising and striking result of Bröcker and Scheiderer (see [Sch89], [Brö91], [BCR98] and [Mah89]) every basic closed semi-algebraic set of the form

$$S = \left\{ x \in \mathbb{R}^d : f_1(x) \geq 0, \ldots, f_l(x) \geq 0 \right\},$$

where $f_i \in \mathbb{R}[x_1, \ldots, x_d]$, $1 \leq i \leq l$, are polynomials, can be represented by at most $d(d+1)/2$ polynomials, i.e., there exist polynomials $p_1, \ldots, p_{d(d+1)/2} \in \mathbb{R}[x_1, \ldots, x_d]$ such that

$$S = \left\{ x \in \mathbb{R}^d : p_1(x) \geq 0, \ldots, p_{d(d+1)/2}(x) \geq 0 \right\}.$$

Moreover, in the case of basic open semi-algebraic sets, i.e., $\geq$ is replaced by strict inequality, one can even bound the maximal number of needed polynomials by the dimension $d$ instead of $d(d+1)/2$.

No explicit constructions, however, of such systems of polynomials are known, even in the very special case of $d$-dimensional convex polyhedra and even if the quadratic upper bound is replaced by any bound depending only on the dimension. In [Brö91], Example 2.10, or in [ABR96], Example 4.7, a description of a regular convex $m$-gon in the plane by two polynomials is given. This result was generalized to arbitrary convex polygons and three polynomial inequalities by vom Hofe [H92]. Bernig [Ber98] proved that, for $d = 2$, every convex polygon can even be represented by two polynomial inequalities. The main purpose of this note is to give some basic properties of polynomials describing polyhedra as well as an explicit construction of (exponentially many) polynomials describing simple $d$-polytopes of any dimension $d$. 
In order to state the result we fix some notation. A polyhedron $P \subset \mathbb{R}^d$ is the intersection of finitely many closed halfspaces, i.e., we can represent it as
\begin{equation}
P = \left\{ x \in \mathbb{R}^d : a^i \cdot x \leq b_i, \ 1 \leq i \leq m \right\},
\end{equation}
for some $a^i \in \mathbb{R}^d, b_i \in \mathbb{R}$. Here $a \cdot x$ denotes the standard inner product on $\mathbb{R}^d$.

If $P$ is bounded then it is called a polytope. In general we are only working with $d$-dimensional polyhedra $P \subset \mathbb{R}^d$, and for short, we denote these polyhedra as $d$-polyhedra. A $d$-polyhedron $P$ is called simple, if every $k$-dimensional face, $0 \leq k \leq d - 1$, belongs to exactly $d - k$ facets of $P$. In the case of polytopes, this is equivalent to the statements that every vertex lies in precisely $d$ facets, or, every vertex figure is a simplex (cf. [Zie95], pp. 65). Since for unbounded polyhedra the above definition of simple polyhedra is not invariant with respect to projective transformation, we call a polyhedron $P$ a strongly simple polyhedron, if it is projectively equivalent to a simple polytope, i.e., for a "$P$-permissible" projective transformation $f : \mathbb{R}^d \to \mathbb{R}^d$, denoted by $\text{cl}(f(P))$, is a simple polytope. For more information about polyhedra, polytopes and their combinatorial structure we refer to the books [MS71] and [Zie95].

For polynomials $p_i \in \mathbb{R}[x_1, \ldots, x_d], 1 \leq i \leq l$, we denote by
\begin{equation}
P(p_1, \ldots, p_l) := \left\{ x \in \mathbb{R}^d : p_1(x) \geq 0, \ldots, p_l(x) \geq 0 \right\}
\end{equation}
the associated closed semi-algebraic set and we define

**Definition 1.1.** A $P$-representation of a $d$-polyhedron $P \subset \mathbb{R}^d$ consists of $l$ polynomials $p_1, \ldots, p_l \in \mathbb{R}[x_1, \ldots, x_d]$ such that
\begin{equation}
P = P(p_1, \ldots, p_l).
\end{equation}

For $d$-polytopes there are two other well known and important representations (see, e.g., [GK97], [Zie95]): The representation of $P$ by $m$ vectors $a^i \in \mathbb{R}^d$ and scalars $b_i$ as given in (1.1) is called $H$-representation of $P$. Of course, any $H$-representation may be regarded as a special $P$-representation of $P$ with linear polynomials (linear forms). As a dual counterpart we have the $V$-representation of a $d$-polytope $P$ consisting of $n$ points $v^i \in \mathbb{R}^d$ such that $P$ is the convex hull of these points, i.e., $P = \text{conv}\{v^1, \ldots, v^n\}$.

Both, $V$- and $H$-representations, are quite powerful and useful representations of polytopes. They admit the computation of the complete combinatorial structure (face-lattice) of the polytope (cf. [GK97], [Sei97]) and linear programming problems can be solved in polynomial time with respect to the input sizes of these representations. Many interesting combinatorial optimization problems, however, cannot be effectively solved via these representations because the size of both representations is exponential in the “natural” input size of the combinatorial problem instances. This holds, e.g., for the polytopes associated with the traveling salesman problem or the max cut problem, see [GLS88] for details.

On the other hand, the result of Bröcker and Scheiderer tells us that there always exists a $P$-representation by polynomially many (with respect to the dimension) polynomials, and therefore, a representation or “good” approximation
of a polytope by few polynomial inequalities could lead to a new approach to “hard” combinatorial optimization problems via nonlinear programming tools. In the last section we discuss this connection in more detail as well as the possible outcomes of such an approach.

For a different approach of approximating “discrete problems” by semi-algebraic sets see [BV93], and for related problems involving polynomials and optimization see, e.g., [Bar02], [BG01], [Las01] and the references within.

Unfortunately, at the moment our knowledge about polynomials representing or approximating polytopes is rather limited. For arbitrary polytopes we even do not know how to convert – via an algorithm – a $H$-representation into a $P$-representation where the number of polynomials depends only on the dimension.

For simple polytopes we have the following result.

**Theorem 1.2.** Let $P \subset \mathbb{R}^d$ be a $d$-dimensional simple polytope given by a $H$-representation. Then $\mu(d) \leq d^d$ polynomials $p_i \in \mathbb{R}[x_1, \ldots, x_d]$ can be constructed such that

$$P = \mathcal{P}(p_1, \ldots, p_{\mu(d)}).$$

In particular, we can take $\mu(2) = 3$ and $\mu(3) = 6$.

Since every 2-dimensional polygon is simple, Theorem 1.2 includes the result of vom Hofe [vH92].

It is not hard to see that if a polyhedron is given as the set of solutions of polynomial inequalities then the sum of the total degrees of these polynomials is at least the number of facets (cf. Proposition 2.1 i)). In fact, the total degrees of the polynomials used in Theorem 1.2 depend on the number of $k$-faces, $k = 0, \ldots, d - 1$, of the polytope as well as on some metric properties of the polytope. For upper bounds on the degrees in the general semi-algebraic setting we refer to [BM98].

All the polynomials that we use in Theorem 1.2 are of a rather special structure, namely, if $P = \{x \in \mathbb{R}^d : a^i \cdot x \leq b_i, 1 \leq i \leq m\}$ then they can be expressed as

$$\sum_{\alpha \in \mathbb{N}^m, \alpha \geq 0} c_\alpha \prod_{i=1}^m [b_i - a^i \cdot x]^\alpha_i,$$

where $c_\alpha$ are certain non-negative numbers and, of course, only finitely many of them are positive. One possible explanation for this special type is given by a result of Handelman [Han88] which says that every polynomial that is strictly positive on a polytope $P$ is of that type. His proof is non-constructive, for a more explicit version see [PR01].

It seems to be an interesting question to ask for the minimal number of polynomials needed to describe a $d$-polyhedron or $d$-polytope. Therefore we define

**Definition 1.3.** For a $d$-polyhedron $P \subset \mathbb{R}^d$, let $m_P(P)$ be the minimal number of polynomials needed in a $P$-representation of $P$ and let

$$\overline{m}_P(d) := \max \left\{ m_P(P) : P \subset \mathbb{R}^d \text{ is a } d\text{-polyhedron} \right\},$$

$$m_P(d) := \max \left\{ m_P(P) : P \subset \mathbb{R}^d \text{ is a } d\text{-polytope} \right\}.$$
We set \( m_P(\mathbb{R}^d) = 0 \), and for a polyhedron \( \tilde{P} \subseteq \mathbb{R}^d \) with \( \dim(\tilde{P}) < d \) we mean by \( m_P(\tilde{P}) \) the minimal number of polynomials in \( \dim(\tilde{P}) \)-variables, which are needed in order to describe an embedding of \( \tilde{P} \) in \( \mathbb{R}^{\dim(\tilde{P})} \).

Observe that \( m_P(P) \) is invariant with respect to regular affine transformations of \( P \). Moreover, it is easy to see that \( m_P(P) \geq d \) for every \( d \)-polytope \( P \) (cf. Corollary 2.2 i)). And together with the result of Bröcker and Scheiderer we obtain

\[
d \leq m_P(d) \leq \overline{m}_P(d) \leq d(d + 1)/2.
\]

In Proposition 2.5 we show \( m_P(d) \leq m_P(d) + 1 \). Probably, the truth is \( m_P(d) = m_P(d) \).

There are some trivial examples of polytopes for which \( d \) polynomials are sufficient. For instance, the cube \( C_d = \{ x \in \mathbb{R}^d : -1 \leq x_i \leq 1 \} \) can be written as \( C_d = \{ x \in \mathbb{R}^d : (x_i)^2 + 1 \geq 0, x_1 + \cdots + x_d \leq 1 \} \). Then it is easy to check that\( T^d = \{ x \in \mathbb{R}^d : x_i (1 - x_i - \cdots - x_d) \geq 0, 1 \leq i \leq d \} \).

Actually, the given representations of a cube and a simplex are special cases of a general construction of polynomial inequalities for prisms and pyramids (cf. Proposition 2.3), which in particular imply that every 3-dimensional prism or pyramid can be described by 3 polynomials (cf. Corollary 2.4). However, we are not aware of a representation of a regular crosspolytope \( C_d^\circ = \{ x \in \mathbb{R}^d : |x_1| + \cdots + |x_d| \leq 1 \} \) by \( d \) polynomials or of any constructive good upper bound on \( m_P(C_d^\circ) \).

In this context it seems to be worth mentioning that a classical result of Minkowski [Min03] implies that a polytope can be approximated “arbitrarily closely” by only one polynomial inequality, where – of course – the degree of this polynomial is “arbitrarily large”. In Section 2 we will construct such a polynomial, which will be used in the scope of the proof of Theorem 1.2. Furthermore, in Section 2 we will state some simple and basic properties of polynomials describing a polyhedron. In Section 3 we give the construction of the polynomials used in Theorem 1.2 and the proof of this theorem. A generalization of the theorem to strongly simple polyhedra is given in Section 4 (cf. Corollary 4.1). Finally, in Section 5 we discuss possible outcomes of research on \( \mathcal{P} \)-representation of polyhedra associated with hard combinatorial optimization problems.

## 2. Polynomials and Polyhedra

Let

\[
P = \left\{ x \in \mathbb{R}^d : a^i \cdot x \leq b_i, 1 \leq i \leq m \right\}
\]

be a \( d \)-dimensional polyhedron. We always assume that the representation (2.1) is irredundant, i.e., \( P \cap \{ x \in \mathbb{R}^d : a^i \cdot x = b_i \} \) is a facet of \( P \), \( 1 \leq i \leq m \). In particular, we have that \( b_i = h(a^i) \), where \( h(\cdot) \) denotes the support function of \( P \), i.e.,

\[
h(u) = \sup \{ u \cdot x : x \in P \}.
\]
For a non-negative linear combination of vectors $\sum_i \rho_i u^i$, $\rho_i \in \mathbb{R}_{\geq 0}$, we have $h(\sum_i \rho_i u^i) \leq \sum_i \rho_i h(u^i)$. The next proposition collects some simple properties of polynomials describing polyhedra.

**Proposition 2.1.** Let $P = \{x \in \mathbb{R}^d : a^i \cdot x \leq b_i, \ 1 \leq i \leq m\}$ be a $d$-polyhedron and let $p_1, \ldots, p_l \in \mathbb{R}[x_1, \ldots, x_d]$ such that $P = \mathcal{P}(p_1, \ldots, p_l)$.

i) Each facet defining linear polynomial $b_i - a^i \cdot x$, $i \in \{1, \ldots, m\}$, is a factor of one of the $p_j$.

ii) Let $F$ be a $k$-dimensional face of $P$. Then there exist $d-k$ polynomials $p_{j_1}, \ldots, p_{j_{d-k}}$, say, such that these polynomials vanish on the affine hull of $F$, i.e.,

$$
\text{aff}F \subset \left\{ x \in \mathbb{R}^d : p_{j_1}(x) = \cdots = p_{j_{d-k}}(x) = 0 \right\}.
$$

**Proof.**

i) Let $F_i = P \cap \{x \in \mathbb{R}^d : a^i \cdot x = b_i\}$. By assumption, $F_i$ is a facet of $P$. First we note that for each $y \in F_i$ one of the polynomials $p_j$ has to vanish. Otherwise, if $p_j(y) > 0$ for all $1 \leq j \leq l$ we get by the continuity of polynomials that we can move $y$ in any direction without leaving $P$, which contradicts the property that $y$ belongs to the boundary. Thus we know that the polynomial

$$
f(x) = \prod_{j=1}^{l} p_j(x)
$$

vanishes on $F_i$. Hence it vanishes on every segment joining two points of $F_i$ and therefore, it has to be 0 on $\text{aff}(F_i) = \{ x \in \mathbb{R}^d : b_i - a^i \cdot x = 0 \}$. Thus $b_i - a^i \cdot x$ is a factor of $f(x)$. Furthermore, since $b_i - a^i \cdot x$ is irreducible, it has to be a factor of one of the $p_j$ (see, e.g., [CLO92], pp. 148).

ii) We use induction with respect to the dimension $k$ of the face $F$ and we start with $k = d-1$. In this case the statement follows immediately from i). So let $k < d-1$ and let $G$ be a $(k+1)$-face containing $F$. By induction we can assume that $\text{aff}(G) \subset \{ x \in \mathbb{R}^d : p_1(x) = p_2(x) = \cdots = p_{d-k}(x) = 0 \}$ and so

$$
G = \text{aff}(G) \cap P = \{ x \in \text{aff}(G) : p_{d-k}(x) \geq 0, \ldots, p_l(x) \geq 0 \}.
$$

With respect to the $(k+1)$-dimensional polytope $G$ in the space $\text{aff}(G)$ the face $F$ is a facet and so we can conclude that one of the polynomials $p_{d-k}, \ldots, p_l$ vanishes on $\text{aff}(F)$.

As an immediate consequence of Proposition 2.1 ii) we note

**Corollary 2.2.**

i) Let $F$ be an non-empty face of a $d$-polyhedron $P \subset \mathbb{R}^d$. Then

$$
m_P(P) \geq m_P(F) + d - \dim(F).
$$

In particular, $m_P(P) \geq d$ for $d$-polytopes.

ii) $m_P(d+1) \geq m_P(d) + 1$ and $\overline{m}_P(d+1) \geq \overline{m}_P(d) + 1$.

**Proof.** Let $P = \mathcal{P}(p_1, \ldots, p_l)$. By Proposition 2.1 ii) we may assume that $\text{aff}(F) \subset \{ x \in \mathbb{R}^d : p_1(x) = \cdots = p_{d-\dim(F)}(x) = 0 \}$. Thus

$$
F = \text{aff}(F) \cap P = \{ x \in \text{aff}(F) : p_{d-\dim(F)+1}(x) \geq 0, \ldots, p_l(x) \geq 0 \}.
$$
and so \( m_P(F) \leq m_P(P) - (d - \dim(F)) \). If \( P \) is a polytope then we may choose for \( F \) a vertex and get \( m_P(P) \geq d \).

For ii) let \( Q \) be a \( d \)-polytope with \( m_P(Q) = m_P(d) \). Now we take any \((d+1)\)-polytope that has \( Q \) as a facet and then we can conclude from i) that \( m_P(P) \geq m_P(d) + 1 \). Of course, the polyhedral case can be treated analogously. \( \square \)

The next statement gives some information on \( m_P(P) \) for \( d \)-prisms and \( d \)-pyramids. A \( d \)-polytope \( P \) is called a \( d \)-pyramid (\( d \)-prism) with basis \( Q \), where \( Q \) is a \((d-1)\)-polytope, if there exists a \( v \in \mathbb{R}^d \) such that \( P = \text{conv}\{Q, v\} \) \((P = Q + \text{conv}\{0, v\} = \{g + \lambda v : q \in Q, \ 0 \leq \lambda \leq 1\})\).

**Proposition 2.3.** Let \( P \) be a \( d \)-prism or a \( d \)-pyramid with basis \( Q \). Then
\[
\ m_P(P) = m_P(Q) + 1.
\]

**Proof.** Since in both cases the \((d-1)\)-polytope \( Q \) is a facet of \( P \) we get from Corollary 2.2 i)
\[
(2.2) \quad m_P(P) \geq m_P(Q) + 1.
\]

In order to show the reverse inequality we start with a \(d\)-dimensional pyramid \( P = \text{conv}\{Q, v\} \) and w.l.o.g. we assume that

\[
(2.3) \quad \begin{aligned}
& i) \ Q \subset \left\{ x \in \mathbb{R}^d : x_d = 0 \text{ and } \sum_{i=1}^{d-1} (x_i)^2 \leq 1 \right\}, \\
& ii) \ v = (0, \ldots, 0, 1)^\top.
\end{aligned}
\]

Let \( l = m_P(Q) \) and \( p_1, \ldots, p_l \in \mathbb{R}[x_1, \ldots, x_{d-1}] \) such that \( Q = \mathcal{P}(p_1, \ldots, p_l) \). Furthermore we denote by \( p \) the maximum of the total degrees of the polynomials \( p_j, \ 1 \leq j \leq l \), and let
\[
\tilde{p}_j(x) = (1 - x_d)^p \cdot p_j \left( \frac{x_1}{1 - x_d}, \ldots, \frac{x_d}{1 - x_d} \right), \quad 1 \leq j \leq l,
\]
\[
p(x) = x_d \left(1 - x_d - x_d \left((x_1)^2 + \cdots + (x_{d-1})^2)\right)\right).
\]

Observe that \( \tilde{p}_j(x) \in \mathbb{R}[x_1, \ldots, x_d],\ 1 \leq j \leq l \). Next we claim that
\[
(2.5) \quad P = \mathcal{P}(\tilde{p}_1, \ldots, \tilde{p}_l, p).
\]

To see this we first note that for \(0 \leq \lambda \leq 1\)
\[
(2.6) \quad P \cap \{x \in \mathbb{R}^d : x_d = \lambda\} = (1 - \lambda)Q + \lambda(0, \ldots, 0, 1)^\top.
\]

A simple calculation shows that, for \(0 \leq \lambda < 1\),
\[
P \cap \{x \in \mathbb{R}^d : x_d = \lambda\}
\]
\[
= \left\{ (x_1, \ldots, x_{d-1}, \lambda)^\top \in \mathbb{R}^d : \tilde{p}_j(x_1, \ldots, x_{d-1}, \lambda) \geq 0, \ 1 \leq j \leq l \right\}.
\]

Next we observe that, for \(x \in P\), we have \(0 \leq x_d \leq 1\). By (2.6) and assumption (2.3) i) we conclude that
\[
(x_1)^2 + \cdots + (x_{d-1})^2 \leq (1 - x_d)^2 \text{ for all } x \in P.
\]

Hence \( p(x) \geq 0 \) for \(x \in P\) and together with (2.7) we get \( P \setminus \{(0, \ldots, 0, 1)^\top\} \subset \mathcal{P}(\tilde{p}_1, \ldots, \tilde{p}_l, p) \) and consequently \( P \subset \mathcal{P}(\tilde{p}_1, \ldots, \tilde{p}_l, p) \).
Corollary 2.4. \([\text{cf. } \cite{Ber98}]\), Proposition 2.3 gives it is easy to check that a vector verified for pyramids.

Therefore, we can assume that the origin is a vertex of \(P\), and we assume that \(0 \in P\). Since for \(d = 1\) the inequality \(p(x) \geq 0\) becomes \((x_1)^2 + \cdots + (x_{d-1})^2 \leq 0\) we conclude that

\[
\mathcal{P}(\tilde{p}_1, \ldots, \tilde{p}_r, p) \cap \{x \in \mathbb{R}^d : x_d = 1\} = \{(0, \ldots, 0, 1)\}.
\]

Hence we also have \(\mathcal{P}(\tilde{p}_1, \ldots, \tilde{p}_r, p) \subset P\). Thus (2.3) is shown and so we have \(m_P(P) \leq m_P(Q) + 1\). Together with (2.2) the statement of the proposition is verified for pyramids.

If \(P = Q + \text{conv}\{0, v\}\) is a \(d\)-prism over the basis \(Q\) and if we assume again that \(v = (0, \ldots, 0, 1)^\top\), \(Q \subset \{x \in \mathbb{R}^d : x_d = 0\}\) and \(Q = \mathcal{P}(p_1, \ldots, p_{m_P(Q)})\) then it is easy to check that

\[
P = \left\{x \in \mathbb{R}^d : p_j(x_1, \ldots, x_{d-1}) \geq 0, 1 \leq j \leq m_P(Q), x_d(1 - x_d) \geq 0\right\}.
\]

Since every 2-dimensional polygon can be described by two polynomials (cf. \cite{Ber98}), Proposition 2.3 gives

\textbf{Corollary 2.4.} Let \(P\) be a 3-dimensional prism or pyramid. Then

\[
m_P(P) = 3.
\]

Next we study the relation between \(m_P(d)\) and \(\overline{m}_P(d)\). Obviously, we have \(m_P(d) \leq \overline{m}_P(d)\). In order to bound \(\overline{m}_P(d)\) in terms of \(m_P(d)\), we apply a standard technique from Discrete Geometry, which “makes an unbounded pointed polyhedron bounded”, namely projective transformations.

\textbf{Proposition 2.5.} Let \(d \geq 2\). Then

\[
m_P(d) \leq \overline{m}_P(d) \leq m_P(d) + 1.
\]

\textit{Proof.} In order to prove the upper bound on \(\overline{m}_P(d)\) let \(P\) be a \(d\)-polyhedron such that \(\overline{m}_P(d) = m_P(P)\). Let \(G\) be a non-empty face of minimal dimension of \(P\), and we assume that \(0 \in G\). Suppose that \(\dim(G) > 0\). Then the intersection of \(P\) with the orthogonal complement of \(\text{lin}(G)\), the linear hull of \(G\), is a lower dimensional polyhedron \(Q\), say. Since \(P = Q + \text{lin}(G) = \{q + g : q \in Q, g \in \text{lin}(G)\}\) any \(P\)-representation of \(Q\) can easily be converted to a \(P\)-representation of \(P\) with the same number of polynomials. With the help of Corollary 2.2 ii) we get the contradiction

\[
\overline{m}_P(d) = m_P(P) = m_P(Q) \leq \overline{m}_P(\dim(Q)) < \overline{m}_P(d).
\]

Therefore, we can assume that the origin is a vertex of \(P\). Thus, we can find a vector \(c \in \mathbb{R}^d\) with \(c \cdot x > 0\) for all \(x \in P \setminus \{0\}\). Let \(f : \mathbb{R}^d \rightarrow \mathbb{R}^d\) be the projective map

\[
f(x) = \frac{x}{c \cdot x + 1}.
\]
Then we can describe $f(P)$ by a set of inequalities of the form $f(P) = \{ x \in \mathbb{R}^d : Ax \leq b, c \cdot x < 1 \}$, for a certain matrix $A \in \mathbb{R}^{m \times d}$ and a vector $b \in \mathbb{R}^m$. The inequality $c \cdot x < 1$ corresponds to the points at infinity.

We conclude that the set (the closure of $f(P)$)

$$\text{cl}(f(P)) = \{ x \in \mathbb{R}^d : Ax \leq b, c \cdot x \leq 1 \}$$

is a $d$-dimensional polytope. Hence we get can find a $\mathcal{P}$-representation of $\text{cl}(f(P))$ by polynomials $p_i$, $i \in I$, say, with $|I| \leq m_\mathcal{P}(d)$. So we may write

$$f(P) = \left\{ x \in \mathbb{R}^d : p_i(x) \geq 0, i \in I, c \cdot x < 1 \right\}.$$

Thus

$$P = \left\{ x \in \mathbb{R}^d \setminus \{ x \in \mathbb{R}^d : c \cdot x = -1 \} : p_i(f(x)) \geq 0, i \in I, c \cdot f(x) < 1 \right\}.$$

Since $c \cdot f(x) < 1$ is equivalent to $c \cdot x + 1 > 0$ we may multiply all rational functions $p_i(f(x))$ by suitable powers of $c \cdot x + 1$ and obtain some polynomials $\tilde{p}_i(x)$, say, such that

$$P = \left\{ x \in \mathbb{R}^d : \tilde{p}_i(x) \geq 0, i \in I, c \cdot x + 1 > 0 \right\}.$$

Since $c \cdot x \geq 0$ for all $x \in P$ we may replace the last inequality in this representation by $c \cdot x \geq 0$ and since $|I| \leq m_\mathcal{P}(d)$ the proposition is shown. \hfill \Box

In the next lemma a strictly convex polynomial $p$ is constructed such that

the convex body $K = \{ x \in \mathbb{R}^d : p(x) \leq 1 \}$ is not “too far away” from $P$. Here the distance between convex bodies $K_1, K_2$ will be measured by the Hausdorff distance $\text{dist}(K_1, K_2)$, i.e.,

$$\text{dist}(K_1, K_2) := \max \left\{ \max_{x \in K_1} \min_{y \in K_2} \| x - y \|, \max_{x \in K_2} \min_{y \in K_1} \| x - y \| \right\},$$

where $\| \cdot \|$ denotes the Euclidean norm. Furthermore, for a bounded set $S \subset \mathbb{R}^d$, the diameter is denoted by $\text{diam}(S)$, i.e.,

$$\text{diam}(S) := \max \{ \| x - y \| : x, y \in S \}.$$ 

In order to construct this strictly convex polynomial we follow an approach of Hammer [Ham63], but since we need a slightly different approximation we give the short proof. For similar results see [Fir74] and [Wei75].

**Lemma 2.6.** Let $P = \{ x \in \mathbb{R}^d : a^i \cdot x \leq b_i, 1 \leq i \leq m \}$ be a $d$-dimensional polytope. For $1 \leq i \leq m$ let

$$v_i(x) := \frac{2a^i \cdot x - h(a^i) + h(-a^i)}{h(a^i) + h(-a^i)}.$$

Let $\epsilon > 0$, $p > \ln(m)/(2 \ln(1 + \frac{2^p}{(d+1)\text{diam}(P^2)}))$, and

$$p_\epsilon(x) := \sum_{i=1}^{m} \frac{1}{m} [v_i(x)]^{2p} \quad \text{and} \quad K_\epsilon := \{ x \in \mathbb{R}^d : p_\epsilon(x) \leq 1 \}.$$

Then we have $P \subset K_\epsilon$ and $\text{dist}(P, K_\epsilon) \leq \epsilon$. 

Proof. Since $|v_i(x)| \leq 1$ for all $x \in P$ we certainly have $P \subseteq K_\epsilon$. W.l.o.g. let
the origin be the center of gravity of $P$ and let $\lambda = \epsilon / \text{diam}(P)$. First we check
that $K_\epsilon \subseteq P_\lambda = \{ x \in \mathbb{R}^d : a^i \cdot x \leq (1 + \lambda) b_i, 1 \leq i \leq m \}$. Let $y \notin P_\lambda$. Then we
may assume $a^1 \cdot y > (1 + \lambda) h(a^1)$ which implies $v_1(y) > 1 + 2 \lambda h(a^1)$
where the last inequality follows from the choice of the origin as the center of
gravity (cf. [BF34], p.52). By the lower bound on $p$ we conclude $(1/m) v_1(y)^{2m} > 1$
and thus $p_\epsilon(y) > 1$, which shows $y \notin K_\epsilon$. Finally we observe that $\text{dist}(P, P_\lambda) \leq \lambda \text{diam}(P)$. $\square$

3. Proof of Theorem 1.2

In the following let

$$P = \left\{ x \in \mathbb{R}^d : a^i \cdot x \leq b_i, 1 \leq i \leq m \right\}$$

be a convex $d$-dimensional simple polytope with $m$ facets. We further assume
that we know all $k$-faces of the polytope as well as the facets containing a given
face. This information can be obtained from the $\mathcal{H}$-representation above by
several (exponential time and space) algorithms (cf. [Sei97]).

We remark that every $k$-face of $P$ is contained in exactly $d-k$ facets. The
set of all $k$-dimensional faces is denoted by $\mathcal{F}_k$, $0 \leq k \leq d - 1$. For a $k$-face $F$
of $P$, let $[F]^1, \ldots, [F]_{d-k}$, $[F]^1 \leq \cdots \leq [F]_{d-k}$, be all indices of vectors $a^i$ such
$a^i \cdot x = b_i$, for all $x \in \text{aff}(F)$. In other words, these are the ordered indices of
all facets containing $F$.

Next, for a $k$-face $F$ and a positive integral vector $w \in \mathbb{N}^{d-k}$, we define

$$a(F, w) := \sum_{j=1}^{d-k} w_j [a[F]^j].$$

Observe that $a(F, w)$ is a support vector of $F$, i.e.,

$$F = P \cap \left\{ x \in \mathbb{R}^d : a(F, w) \cdot x = h(a(F, w)) \right\}.$$

Moreover, since $F$ is contained in all the facets corresponding to the vectors
$a[F]^j$ we note that

$$h(a(F, w)) = \sum_{j=1}^{d-k} w_j h(a[F]^j).$$

With $w \in \mathbb{N}^{d-k}$ and the set $\mathcal{F}_k$ of all $k$-faces we associate the polynomial

$$p_{k, w}(x) := \prod_{F \in \mathcal{F}_k} [h(a(F, w)) - a(F, w) \cdot x].$$

So, for a fixed $w$ the polynomial $p_{k, w}(x)$ is the product of all those supporting
hyperplanes of all $k$-faces of $P$ which can be written as in (3.1). Since we are
only interested in finitely many different support vectors of the type \( a(F,w) \) at a given face \( F \) we define certain sets of integral vectors:

\[
W_{d-1} := \{(1)\}, \quad W_{d-k} := \{(2^{k_1}, \ldots, 2^{k_k})^\tau : 0 \leq l_i \leq k - 2\}, \quad 2 \leq k \leq d.
\]

In particular we have \( W_{d-2} = \{(1, 1)\} \) and

\[
(3.4) \quad \#W_k = (d - k - 1)^{d-k}.
\]

The meaning of these sets \( W_k \) will be explained in the next lemma.

**Lemma 3.1.** Let \( P \) be a simple \( d \)-dimensional polytope. Let \( k \geq 1, \ F, G \in \mathcal{F}_k \) with \( F \cap G \neq \emptyset \) and let \( w \in W_k, \ y \in \mathbb{R}^d \) such that

\[
(3.5) \quad h(a(F,w)) - a(F,w) \cdot y < 0 \quad \text{and} \quad h(a(G,w)) - a(G,w) \cdot y \leq 0.
\]

Then there exists an \( \tilde{w} \in W_{\dim(F \cap G)} \) such that

\[
(3.6) \quad h(a(F \cap G, \tilde{w})) - a(F \cap G, \tilde{w}) \cdot y < 0.
\]

**Proof.** In view of \( (3.2) \) we conclude from \( (3.5) \) that

\[
\sum_{j=1}^{d-k} w_j \left( h(a[F]_j) - a[F]_j \cdot y \right) < 0,
\]

\[
\sum_{j=1}^{d-k} w_j \left( h(a[G]_j) - a[G]_j \cdot y \right) \leq 0.
\]

Let \( I_1 = \{[F]_1, \ldots, [F]_{d-k}\}, \ I_2 = \{[G]_j : h(a[G]_j) - a[G]_j \cdot y \leq 0\}, \ I_3 = \{[G]_j : h(a[G]_j) - a[G]_j \cdot y > 0\} \) and let \( I = I_1 \cup I_2 \cup I_3 \).

Further, we need a map \( \tau \) that gives, for a \( k \)-face \( F \) and a number \( q \in \{[F]_1, \ldots, [F]_{d-k}\} \), the position of \( q \) with respect to the ordered list \( [F]_1, \ldots, [F]_{d-k} \). In particular we have \( \tau(F, [F]_j) = j \). Now we merge the two normal vectors \( a(F,w), a(G,w) \) in the following way: Let

\[
a = \sum_{j \in I_1 \cap I_2} 2 \max\{w_{\tau(F,j)}, w_{\tau(G,j)}\} a^j + \sum_{j \in I_1 \cap I_3} a^j + \sum_{j \in (I_2 \cup I_3) \setminus I_1} w_{\tau(G,j)} a^j + \sum_{j \in I_1 \setminus (I_2 \cup I_3)} w_{\tau(F,j)} a^j.
\]

On account of \( (3.6) \) we have

\[
h(a) - a \cdot y < 0.
\]

Since the polytope is simple, the assumption \( F \cap G \neq \emptyset \), implies that the vectors \( \{a^j : j \in I\} \) are the vectors of all facets containing the face \( F \cap G \) and by construction we may write \( a = \sum_{j \in I} \tilde{w}_j a^j \) for some numbers \( \tilde{w}_j = 2^{l_j} \) with \( 0 \leq l_j \leq d - k - 1 \).

Thus we have \( a = a(F \cap G, \tilde{w}) \) for a certain vector \( \tilde{w} \in W_{\dim(F \cap G)} \). \( \square \)
Finally let
\[ \varepsilon \geq (3.11) \]
\[ \varepsilon \leq 0 \]
\[ \varepsilon (3.10) \]
We note that for different vertices \( P \) we have (cf. (3.4))
\[ \varepsilon (3.9) \]
Here for a set of polynomials \( P \) we associate the following sets of polynomials:
\[ \varepsilon (3.8) \]
\[ \varepsilon (3.7) \]
\[ \varepsilon (3.6) \]
\[ \varepsilon (3.5) \]
\[ \varepsilon (3.4) \]
\[ \varepsilon (3.3) \]
\[ \varepsilon (3.2) \]
\[ \varepsilon (3.1) \]
\[ \varepsilon (2.6) \]
\[ \varepsilon (2.5) \]
\[ \varepsilon (2.4) \]
\[ \varepsilon (2.3) \]
\[ \varepsilon (2.2) \]
\[ \varepsilon (2.1) \]
We need one more polynomial. To this end we set for two vectors \( a, b \in \mathbb{R}^d \backslash \{0\} \)
\[ U(a, b) = \left\{ x \in \mathbb{R}^d : a \cdot x \geq h(a) \text{ and } b \cdot x \geq h(b) \right\} . \]
\[ U(a, b) \] is a closed set and so we can define
\[ \epsilon(a, b) = \min \{ \|x - y\| : x \in P, y \in U(a, b) \} . \]
Since \( P \subset \left\{ x \in \mathbb{R}^d : a \cdot x \leq h(a), b \cdot x \leq h(b) \right\} \) and both planes \( \left\{ x \in \mathbb{R}^d : a \cdot x = h(a) \right\}, \left\{ x \in \mathbb{R}^d : b \cdot x = h(b) \right\} \) are supporting hyperplanes we have
\[ \epsilon(a, b) = 0 \iff \left\{ x \in \mathbb{R}^d : a \cdot x = h(a) \text{ and } b \cdot x = h(b) \right\} \cap F_0 \neq \emptyset . \]
For \( 0 \leq k \leq d - 1 \) we set
\[ \epsilon_k = \min \left\{ \epsilon \left( a(F, w), a(\tilde{F}, w) \right) : F \neq \tilde{F} \in \mathcal{F}_k, w \in \mathcal{W}_k \right\} . \]
We note that for different vertices \( v, \tilde{v} \in \mathcal{F}_0, w \in \mathcal{W}_0 \), we always have (cf. (3.10))
\[ \epsilon(a(v, w), a(\tilde{v}, w)) > 0 . \]
Finally let \( \tau \) satisfying
\[ 0 < \tau < \min \{ \epsilon_k : 0 \leq k \leq d - 1 \} . \]
With respect to \( \tau \) let \( \mathcal{P} \) \( \mathcal{P} \) be the polynomial according to Lemma 2.6 and let
\[ \mathcal{V}_1(P) = \left\{ x \in \mathbb{R}^d : \mathcal{P}_k(x) \geq 0, 1 \leq k \leq d - 1, \mathcal{P}(x) \leq 1 \right\} , \]
\[ \mathcal{V}_2(P) = \left\{ x \in \mathbb{R}^d : \mathcal{P}_0(x) \geq 0 \right\} . \]
Here for a set of polynomials \( \mathcal{P} \), say, \( \mathcal{P}(x) \geq 0 \) means \( \mathcal{P}(x) \geq 0 \) for all \( \mathcal{P}(x) \in \mathcal{P} \).
Before giving the last piece of the proof of Theorem 1.2 we remark that in order to find a number \( \tau \) satisfying (3.13) we have to calculate several distances \( \epsilon(a, b) \). In general, \( \epsilon(a, b) \) can be calculated (or sufficiently well approximated) by several LP-based methods (cf. [MSW96]). In particular, depending on the input size of the polytope and the vectors \( a, b \) one can give a lower bound on
this distance if it is positive. Thus for a given polytope we can calculate such an \( \tau \) and hence the polynomial \( p_\tau(x) \).

**Proof of Theorem 1.2.** On account of (3.3) and (3.7) the theorem will follow from the identity

\[
(3.14) \quad P = V_1(P) \cap V_2(P).
\]

Obviously, by the definition of all these polynomials via support vectors and by Lemma 2.6 we know that \( P \) is contained in the set on the right hand side. In order to prove the reverse inclusion we first claim

**Claim 3.2.** Let \( y \notin P \), but \( y \in V_1(P) \). Then there exists a vertex \( v \) of \( P \) and an \( w \in W_0 \) such that \( h(a(v, w)) - a(v, w) \cdot y < 0 \).

Since \( y \notin P \) at least one of the inequalities \( a^i \cdot x \leq b_i, \ i \in \{1, \ldots, m\} \), is violated and so we may define \( k \) as the smallest dimension such that there exists a face \( F \in F_k \) and an \( w \in W_k \) with \( h(a(F, w)) - a(F, w) \cdot y < 0 \). Suppose \( k > 0 \). Since \( y \in V_1(P) \) we have \( p_{k, w}(y) \geq 0 \) and so there must exist another \( k \)-face \( G \) with \( h(a(G, w)) - a(G, w) \cdot y \leq 0 \). Hence we have

\[
y \in U(a(F, w), a(G, w)).
\]

If \( e(a(F, w), a(G, w)) > 0 \) then we get from the definition of \( \tau \) and the approximating property of the polynomial \( p_\tau(x) \) (cf. Lemma 2.6) that \( p_\tau(y) > 1 \). Thus we can assume that \( e(a(F, w), a(G, w)) = 0 \) and from (3.10) we get \( F \cap G \neq \emptyset \).

Therefore we may apply Lemma 3.1 and we get a contradiction of the minimality of \( k \). This shows Claim 3.2.

Now let \( y \notin P \). We want to show that \( y \) is not contained in the set \( V_1(P) \cap V_2(P) \). Suppose that \( y \in V_1(P) \cap V_2(P) \). By Claim 3.2 we may assume that there exists a vertex \( v \in F_0 \) and an \( w \in W_0 \) such that \( h(a(v, w)) - a(v, w) \cdot y < 0 \). However, \( y \in V_2(P) \) implies \( p_{0, w}(y) \geq 0 \) and thus there exists another vertex \( \tilde{v} \) with \( h(a(\tilde{v}, w)) - a(\tilde{v}, w) \cdot y \leq 0 \). Therefore we have

\[
y \in W(a(v, w), a(\tilde{v}, w)).
\]

Next we observe that \( e(a(v, w), a(\tilde{v}, w)) > 0 \) (cf. (3.12)) and by the definition of \( \tau \) we conclude \( p_\tau(y) > 1 \), which gives the contradiction \( y \notin V_1(P) \).

\( \square \)

4. Remarks

First we want to generalize Theorem 1.2 to the class of strongly simple polyhedra. As in the case of polytopes, a \( \mathcal{H} \)-representation of a polyhedron \( P \) is a description of \( P \) by linear inequalities of the form \( \{1\} \).

**Corollary 4.1.** Let \( P \subset \mathbb{R}^d \) be a \( d \)-dimensional strongly simple polyhedron given by a \( \mathcal{H} \)-representation. Then \( \mu(d) \leq d^2 \) polynomials \( p_i \in \mathbb{R}[x_1, \ldots, x_d] \) can be constructed such that

\[
P = \left\{ x \in \mathbb{R}^d : p_i(x) \geq 0, \ 1 \leq i \leq \mu(d) \right\}.
\]
Proof. The proof is just a combination of the proofs of Proposition 2.3 and Theorem 1.2. As in the proof of Proposition 2.3 we first note that we can assume that $P$ has a vertex. Next we apply a projective transformation $f(x) = x/(c \cdot x + 1)$ such that $\text{cl}(f(P))$ becomes a polytope. By the definition of strongly simple polyhedra, $\text{cl}(f(P))$ is a $d$-dimensional simple polytope. Hence, from Theorem 1.2, we get a representation of the type

$$ f(P) = \{ x \in \mathbb{R}^d : p_i(x) \geq 0, i \in I, c \cdot x < 1 \} $$

with certain polynomials $p_i(x)$, $i \in I$, $\#I \leq \mu(d)$. Now we can proceed as in the proof of Proposition 2.3 in order to get a $\mathcal{P}$-representation of $P$ with $\mu(d) + 1$ polynomials. A closer look on the number $\mu(d)$ shows that $\mu(d) < d^d$ for $d \geq 2$ (cf. (1.3)) and so the assertion is proved.

We remark that the proofs of Theorem 1.2 and of Corollary 4.4 can be adapted such that for arbitrary polyhedra a representation by polynomials is obtained where the number of polynomials depends exponentially on the dimension and the maximal degree of a vertex of the polytope. In other words, degeneracy in the sense of linear programming leads to additional difficulties. Since, however, the main problem is to find a representation of a polytope by a few polynomials we omit a proof of this statement.

In the 2-dimensional case the meaning of the polynomials $p_1(x)$, $p_0(x)$ and $p_{-1}(x)$ can easily be illustrated. Suppose the polygon is the 7-gon depicted in these pictures. Then the shaded region on the left hand side of Figure 4 shows

$$ \{ x \in \mathbb{R}^d : p_1(x) \geq 0 \} $$

all points in the plane that satisfy the inequality $p_1(x) \geq 0$, whereas the shaded regions on the right hand side correspond to the points $p_0(x) \geq 0$. If we intersect the shaded regions of both pictures we get the points satisfying both inequalities (see Figure 4).
We see that all the shaded points that do not belong to the polygon are “far away” from the polygon and thus we can cut them off with the inequality $p_\tau(x) \leq 1$.

Now let $P = \{x \in \mathbb{R}^3 : a^i \cdot x \leq b_i, 1 \leq i \leq m\}$ be a simple 3-dimensional convex polytope. With the notation from section 3 we get the following polynomials (cf. (3.7))

\[
p_2(x) = \prod_{i=1}^{m} [b_i - a^i \cdot x],
\]
\[
p_1(x) = \prod_{F \in \mathcal{F}} \left[ (b_{[F]_1} + b_{[F]_2}) - (a^{[F]_1} + a^{[F]_2}) \cdot x \right],
\]
\[
p_{0,(1,1,2)}(x) = \prod_{v \in \mathcal{V}_0} \left[ (b_{[v]_1} + b_{[v]_2} + 2 b_{[v]_3}) - (a^{[v]_1} + a^{[v]_2} + 2 a^{[v]_3}) \cdot x \right],
\]
\[
p_{0,(1,2,1)}(x) = \prod_{v \in \mathcal{V}_0} \left[ (b_{[v]_1} + 2 b_{[v]_2} + b_{[v]_3}) - (a^{[v]_1} + 2 a^{[v]_2} + a^{[v]_3}) \cdot x \right],
\]
\[
p_{0,(2,1,1)}(x) = \prod_{v \in \mathcal{V}_0} \left[ (2 b_{[v]_1} + b_{[v]_2} + b_{[v]_3}) - (2 a^{[v]_1} + a^{[v]_2} + a^{[v]_3}) \cdot x \right],
\]
\[
p_\tau(x) = \sum_{i=1}^{m} \frac{1}{m} \left[ 2a^i \cdot x - b_i + h(-a^i) \right]^{2p},
\]

where $\tau$ has to be chosen such that (3.13) is satisfied, and $p$ is given by Lemma 2.6. Let us consider a “real” 3-dimensional polytope $P = \{x \in \mathbb{R}^d : Ax \leq b\},$
with

\[
A = \begin{pmatrix}
0 & 3 & 2 \\
0 & -3 & 2 \\
2 & 0 & 3 \\
2 & 0 & -3 \\
3 & 2 & 0 \\
-3 & 2 & 0 \\
0 & -3 & -2 \\
0 & 3 & -2 \\
-2 & 0 & -3 \\
-2 & 0 & 3 \\
-3 & -2 & 0 \\
3 & -2 & 0
\end{pmatrix}, \quad b = \begin{pmatrix}
5 \\
6 \\
5 \\
4 \\
5 \\
5 \\
6 \\
5 \\
6 \\
5 \\
4 \\
6
\end{pmatrix}.
\]

\(P\) is a simple polytope with 12 facets, all of them pentagons, 30 edges, 20 vertices, and it may be described as a “skew” dodecahedron (see Figure 3).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{dodecahedron.png}
\caption{(produced using polymake \cite{GJ01} and javaview \cite{PKPE02})}
\end{figure}

With respect to the facets we get the polynomial

\[
p_2(x) = (5 - 3x_2 - 2x_3)(6 + 3x_2 - 2x_3)(5 - 2x_1 - 3x_3)(4 - 2x_1 + 3x_3)
\]

\[
(5 - 3x_1 - 2x_2)(5 + 3x_1 - 2x_2)(6 + 3x_2 + 2x_3)(5 - 3x_2 + 2x_3)
\]

\[
(6 + 2x_1 + 3x_3)(5 + 2x_1 - 3x_3)(4 + 3x_1 + 2x_2)(6 - 3x_1 + 2x_2).
\]

For the 30 edges we obtain

\[
p_1(x) = (10 - 2x_1 - 3x_2 - 5x_3)(10 + 2x_1 - 3x_2 - 5x_3)(10 + 3x_1 + -5x_2 - 2x_3)
\]

\[
(10 - 6x_2)(10 - 3x_1 - 5x_2 - 2x_3)(11 - 2x_1 + 3x_2 - 5x_3)
\]

\[
(12 - 3x_1 + 5x_2 - 2x_3)(12 + 6x_2)(10 + 3x_1 + 5x_2 - 2x_3)
\]

\[
(11 + 2x_1 + 3x_2 - 5x_3)(10 - 6x_3)(11 - 5x_1 + 2x_2 - 3x_3)
\]

\[
(10 - 5x_1 + 2x_2 - 3x_3)(9 - 5x_1 - 2x_2 + 3x_3)(10 - 5x_1 + 2x_2 + 3x_3)
\]

\[
(10 - 2x_1 + 3x_2 + 5x_3)(10 + 6x_3)(9 - 2x_1 - 3x_2 + 5x_3)
\]

\[
(10 - 3x_1 - 5x_2 + 2x_3)(11 - 6x_3)(11 + 5x_1 - 2x_2 - 3x_3)
\]

\[
(9 + 6x_1)(11 + 5x_1 - 2x_2 + 3x_3)(10 + 3x_1 - 5x_2 + 2x_3)
\]

\[
(12 - 3x_1 + 5x_2 + 2x_3)(12 + 2x_1 + 3x_2 + 5x_3)(10 + 3x_1 + 5x_2 + 2x_3)
\]

\[
(11 + 2x_1 + -3x_2 + 5x_3)(10 + 5x_1 + 2x_2 + 3x_3)(9 + 5x_1 + 2x_2 - 3x_3).
\]
With respect to the 20 vertices we get 3 polynomials depending on the weights \( w \in W_0 = \{(1, 1, 2), (1, 2, 1), (2, 1, 1)\} \).

\[ p_{0,(1,1,2)}(x) = (20 - 8x_1 - 7x_2 - 5x_3)(20 + 2x_1 - 3x_2 - 11x_3)(20 + 3x_1 - 11x_2 - 2x_3) \]
\[ = (20 + 3x_1 - 11x_2 - 2x_3)(20 + 7x_1 - 5x_2 - 8x_3)(21 + 2x_1 + 3x_2 - 11x_3) \]
\[ = (23 + 8x_1 + 7x_2 - 5x_3)(20 + 6x_1 + 10x_2)(24 - 6x_1 + 10x_2) \]
\[ = (19 + 8x_1 + 7x_2 - 5x_3)(22 - 11x_1 + 2x_2 - 3x_3)(19 - 5x_1 - 8x_2 + 7x_3) \]
\[ = (21 + 11x_1 + 2x_2 + 3x_3)(22 + 2x_1 + 3x_2 + 11x_3)(22 - 8x_1 + 7x_2 + 5x_3) \]
\[ = (21 + 2x_1 - 3x_2 + 11x_3)(22 + 7x_1 - 5x_2 + 8x_3)(19 + 11x_1 + 2x_2 + 3x_3) \]
\[ = (18 + 11x_1 + 2x_2 - 3x_3)(20 + 8x_1 + 7x_2 + 5x_3), \]

\[ p_{0,(1,2,1)}(x) = (20 - 7x_1 - 5x_2 - 8x_3)(20 - 2x_1 - 3x_2 - 11x_3)(20 - 6x_1 - 10x_2) \]
\[ = (20 + 6x_1 - 10x_2)(20 + 8x_1 - 7x_2 - 5x_3)(21 - 2x_1 + 3x_2 - 11x_3) \]
\[ = (22 - 7x_1 + 5x_2 - 8x_3)(22 + 3x_1 + 11x_2 + 2x_3)(24 - 3x_1 + 11x_2 + 2x_3) \]
\[ = (20 + 7x_1 + 5x_2 - 8x_3)(21 - 11x_1 - 2x_2 - 3x_3)(19 - 8x_1 - 7x_2 + 5x_3) \]
\[ = (20 - 11x_1 - 2x_2 + 3x_3)(22 + 6x_2 + 10x_3)(22 - 5x_1 + 8x_2 + 7x_3) \]
\[ = (20 - 6x_2 + 10x_3)(21 + 5x_1 - 8x_2 + 7x_3)(21 + 10x_1 + 6x_3) \]
\[ = (19 + 10x_1 - 6x_3)(22 + 7x_1 + 5x_2 + 8x_3), \]

\[ p_{0,(2,1,1)}(x) = (20 - 5x_1 - 8x_2 - 7x_3)(20 - 6x_2 - 10x_3)(20 - 3x_1 - 11x_2 - 2x_3) \]
\[ = (20 + 3x_1 - 11x_2 - 2x_3)(20 + 5x_1 - 8x_2 - 7x_3)(22 + 6x_2 - 10x_3) \]
\[ = (23 - 5x_1 + 8x_2 - 7x_3)(22 + 3x_1 + 11x_2 - 2x_3)(24 - 3x_1 + 11x_2 - 2x_3) \]
\[ = (21 + 5x_1 + 8x_2 - 7x_3)(21 - 10x_1 - 6x_3)(18 - 7x_1 - 5x_2 + 8x_3) \]
\[ = (19 - 10x_1 + 6x_3)(20 - 2x_1 + 3x_2 + 11x_3)(20 - 7x_1 + 5x_2 + 8x_3) \]
\[ = (19 - 2x_1 - 3x_2 + 11x_3)(21 + 8x_1 - 7x_2 + 5x_3)(20 + 11x_1 - 2x_2 + 3x_3) \]
\[ = (19 + 11x_1 - 2x_2 - 3x_3)(22 + 5x_1 + 8x_2 + 7x_3). \]

Next we have to determine an \( \tau \) as defined in (3.13). To this end we have estimated all the needed distances \( \epsilon_k \) (cf. (3.11)) by a rather ad hoc method and found

\[ \epsilon_2 > 1/10, \quad \epsilon_1 > 3/50, \quad \epsilon_0 > 3/100. \]

Hence we may set \( \tau = 3/100 \) and since \( \text{diam}(P) \leq 4 \) we may choose for the exponent \( p \) of Lemma 2.6 \( p = 332 \). With these values we get from Lemma 2.6 the following polynomial \( p(x) \)

\[ p(x) = \frac{1}{12} \left[ \frac{6x_2 + 4x_3 + 1}{11} \right]^{664} + \frac{1}{12} \left[ \frac{-6x_2 + 4x_3 - 1}{11} \right]^{664} + \frac{1}{12} \left[ \frac{4x_1 + 6x_3 + 1}{11} \right]^{664} \]
\[ + \frac{1}{12} \left[ \frac{4x_1 - 6x_3 + 1}{9} \right]^{664} + \frac{1}{12} \left[ \frac{-6x_2 + 4x_3 - 1}{9} \right]^{664} + \frac{1}{12} \left[ \frac{4x_1 - 6x_3 + 1}{11} \right]^{664} \]
\[ + \frac{1}{12} \left[ \frac{4x_1 + 6x_3 - 1}{9} \right]^{664} + \frac{1}{12} \left[ \frac{-6x_2 - 4x_3 - 1}{11} \right]^{664} + \frac{1}{12} \left[ \frac{4x_1 + 6x_3 - 1}{9} \right]^{664} \]
\[ + \frac{1}{12} \left[ \frac{-6x_2 - 4x_3 - 1}{9} \right]^{664} + \frac{1}{12} \left[ \frac{4x_1 + 6x_3 - 1}{11} \right]^{664} \]

5. Outlook

Why should anyone care about the representation of polyhedra by exponentially many polynomial inequalities, given that one knows that quadratically many suffice? Our answer is that the latter result is of pure existential nature, while we can construct such inequalities. We admit that the representations we found do not form an achievement of concrete practical value. That is why we did not state them in an algorithmic fashion. We see our paper just as a small step towards a development of real algebraic geometry in a constructive
direction. There are a number of possible routes. We want to mention briefly what we are interested in and what might be achievable.

It would be nice to have efficient (in a sense that can be made precise) algorithms that provide, e.g., for polytopes $P$ given in the form of a $V$- or $H$-representation, a $P$-representation $P = \mathcal{P}(p_1, \ldots, p_l)$ with a number $l$ of polynomials that is polynomially bounded in the dimension of the polytope. It may also be useful to be able to construct a small number of “simple” polynomials $p_1, \ldots, p_k$ such that $\mathcal{P}(p_1, \ldots, p_k)$ approximates $P$ well. Of course, one can study similar problems concerning the representation of arbitrary semi-algebraic sets. E.g., given a semi-algebraic set $S$, can it be represented by a system of polynomials with total degree at most $k$, say? Can such a system be constructed efficiently? How well can $S$ be approximated by polynomials of degree $k$? For polyhedra $P$ we know that there exists a representation by polynomials of total degree 1, but what can we say about the minimum number of polynomials of degree $k$ representing $P$?

To indicate possible outcomes that may result from such a change of representation, let us look at the very successful polyhedral approach to combinatorial optimization. The basic idea here is to represent combinatorial objects (such as the tours of a travelling salesman, the independent sets of a matroid, or the stable sets in a graph) as the vertices of a polytope. This way one arrives at an (implicit) $V$-representation of classes of polytopes such as travelling salesman or stable set polytopes. If one can find complete or tight partial representations of polytopes of this type by linear equations and inequalities (i.e., $H$-representations), linear programming (LP) techniques can be employed to solve the associated combinatorial optimization problem, see [GLS88].

This approach provides a general machinery to establish the polynomial time solvability of combinatorial problems theoretically. In particular, it is often employed to identify easy special cases of generally hard problems. One such example is the stable set problem that is $NP$-hard for general graphs but solvable in polynomial time for perfect (and other classes of) graphs, see [GLS88], Chapter 9.

The LP approach provides more. Even in the case where only partial $H$-representations of the polyhedra associated with combinatorial problems are known, LP techniques (such as cutting planes and column generation) have resulted in very successful exact or approximate solution methods. One prime example for this methodology is the travelling salesman problem, see [ABCC98] and the corresponding web page at [http://www.math.princeton.edu/tsp/](http://www.math.princeton.edu/tsp/), which includes an annotated bibliography with remarks about the historical development of this area.

Progress of the type may also be possible via the “$P$-representation approach”. Let us discuss this by means of the stable set problem.

Although complexity theory suggests that it is inconceivable that one can find an explicit $P$-representation of all members of the class of stable set polytopes, i.e., the convex hull of all incidence vectors of stable sets, it might be possible to find, for every graph $G$, a ”small” number $l(G)$ of not too ”ugly” polynomials
such that \( P(p_1, \ldots, p_{l(G)}) \) approximates the stable set polytope \( \text{STAB}(G) \) well, and such that \( P(p_1, \ldots, p_{l(G)}) \) equals \( \text{STAB}(G) \) for a special class of graphs.

It is also conceivable that, for such particular systems \( p_1, \ldots, p_{l(G)} \) of polynomials, special nonlinear programming algorithms can be designed that solve optimization problems over \( P(p_1, \ldots, p_{l(G)}) \) efficient in practice or theory.

We do know, of course, that these indications of possible future results are mere speculation. Visions of this type, however, were the starting point of the results presented in this paper. And we do hope that there will be progress in some of the directions mentioned.

Acknowledgment. We would like to thank Monika Ludwig and Günter M. Ziegler for helpful discussions, and Michael Joswig for pointing out a mistake in a previous version of Corollary 4.1 and for giving suggestions for improvements. We are grateful to the anonymous referees for their helpful comments.
