1. Introduction

Autism Spectrum Disorders (ASD) is a developmental disorder involving abnormal communication and interaction within society along with other behavioral problems. These are also grouped as Pervasive Developmental Disorder (PDD). Its estimated reported incidence is about 1% of the population. Various kind of disorders are grouped under ASD and include autistic disorders, Asperger’s disorder and PDD not otherwise specified (PDD NOS). Usually diagnosed in early childhood, their presence is well recognized in adults. The bone density in patients affected with ASD has been found to be subnormal and decreased exercise and low vitamin D through diet or sun exposure might be additional causes for it. The decreased bone mass may cause fractures but the literature regarding fracture in these cases is limited. The treatment part is compounded with problems of social and behavioral disorders inherent to ASD.

2. Case Report

A 28 year old female patient was brought to us with history of fall on wet bathroom floor and landing on her right arm. There was pain, deformity and disability in using the affected extremity since the injury. She was carried by her guardians with a sling of ‘dupatta’ (Indian stole). On examination visible deformity and abnormal mobility at middle of right arm was clinically suggestive of fracture. The distal neurovascular status was intact. The injury was closed and no remote or related injuries noted. The radiograph of the arm in orthogonal planes showed a short oblique mid shaft humerus fracture (Figure 1). The lady, according to history given by attendants was diagnosed case of autism and mental retardation. She was diagnosed in early childhood and initial workup and multiple opinions and treatment was taken with little clinical benefit. She is home bound as she has problem with socializing and communication. She was reluctant to visit anywhere for this injury as well and was somehow
carried for treatment. The operative management and
detailed investigation work up, as per standard protocol
in our tertiary care referral centre, was declined by the
patient and parents.

3. Result

The fracture showed signs of union in the follow up
radiograph and united well after two months of treatment.
The union, however, was not anatomical but satisfactory
with minimal shortening or angulations (Figure 3). No
functional limitation was noted after short period of
physiotherapy as patient resumed activities of daily living.
No early or remote complication related to the fracture
and technique was noted.

4. Discussion

Low bone density has been attributed to increased risk
of fractures and associated complications. The ASD cases
have reportedly abnormal bone density thus increased
risk for fractures4. Young and adult cases of ASD have
been found to have an increased odds ratio of fracture
around hip, forearm and spine3,5. Our case reported
trivial fall resulting in a closed short oblique fracture
pattern and that suggests subnormal bone strength6.
Associated disorders related to mood and anxiety in cases
with ASD is also commonly encountered. These coupled
with social interaction issues create problem in the
treatment of fractures7,8. There are ample reasons for non-
compliance or adverse outcome of conservative outcome.
The treatment opted by our case was conservative
and conservative care requires periodic evaluation of radiographs and that of plaster or other splints to ensure adequacy and safety of the treatment. The additional feature of mental retardation in our case demanded cautious treatment option planning and vigilant support of attendants and guardians. With this background, we opted for functional bracing of the fracture right away as it will be least interfering and equally efficacious to the patient. The caution should be exercised to proactively evaluate for unsatisfactory displacement or complication of the conservative care all through the treatment period.

5. Conclusion

The management of fractures in the cases of autism spectrum disorder is challenging in many ways and judicious selection of treatment and supporting gesture of attendants is critical in satisfactory functional outcome.
