Abstract
We examine the percolation model on $\mathbb{Z}^d$ by an approach involving lattice animals and their surface-area-to-volume ratio. For $\beta \in [0, 2(d - 1))$, let $f(\beta)$ be the asymptotic exponential rate in the number of edges of the number of lattice animals containing the origin which have surface-area-to-volume ratio $\beta$. The function $f$ is bounded above by a function which may be written in an explicit form. For low values of $\beta$ ($\beta \leq 1/p_c - 1$), equality holds, as originally demonstrated by F. Delyon. For higher values ($\beta > 1/p_c - 1$), the inequality is strict.

We introduce two critical exponents, one of which describes how quickly $f$ falls away from the explicit form as $\beta$ rises from $1/p_c - 1$, and the second of which describes how large clusters appear in the marginally subcritical regime of the percolation model. We demonstrate that the pair of exponents must satisfy certain inequalities. Other such inequalities yield sufficient conditions for the absence of an infinite cluster at the critical value (c.f. [4]). The first exponent is related to one of a more conventional nature in the scaling theory of percolation, that of correlation size. In deriving this relation, we find that there are two possible behaviours, depending on the value of the first exponent, for the typical surface-area-to-volume ratio of an unusually large cluster in the marginally subcritical regime.

1 Introduction

We examine the percolation model by an approach involving lattice animals, divided according to their surface-area-to-volume ratio. Throughout, we work with the bond percolation model in $\mathbb{Z}^d$. However, the results apply to the site or bond model on any infinite transitive amenable graph with inessential changes.

For any given $p \in (0, 1)$, two lattice animals with given size are equally likely to arise as the cluster $C(0)$ containing the origin provided that they have the same surface-area-to-volume ratio. For given $\beta \in (0, \infty)$, there is an exponential growth rate in the number of edges for the number of lattice animals up to translation that have surface-area-to-volume ratio very close to $\beta$. This growth rate $f(\beta)$ may be studied as a function of $\beta$. To illustrate the connection

1Research supported by Merton College, Oxford
between the percolation model and the combinatorial question of the behaviour of $f$, note that the probability that the cluster containing the origin contains a large number $n$ of edges is given by
\[
\mathbb{P}_p(|C(0)| = n) = \sum_m \sigma_{n,m} p^n(1-p)^m,
\]
where $\sigma_{n,m}$ is the number of lattice animals that contain the origin, have $n$ edges and $m$ outlying edges. We rewrite the right-hand-side to highlight the role of the surface-area-to-volume ratio, $m/n$:
\[
\mathbb{P}_p(|C(0)| = n) = \sum_m (f_n(m/n)p(1-p)^{m/n})^n.
\]
Here $f_n(\beta) = (\sigma_{n,\beta m})^{1/n}$ is a rescaling that anticipates the exponential growth that occurs. We examine thoroughly the link between percolation and combinatorics provided by (2): how do the quantities $f_n(\beta)$ scale for high $n$, and in which range of values of $m$ is the expression in (2) carrying most of its weight? These questions are hardly new, and the techniques of proof we have employed in seeking answers are not strikingly novel. However, in pursuing answers, we have found two critical exponents that arise naturally in this approach, and some inequalities that this pair must satisfy. Trying to determine the relationships satisfied by such exponents is a central task in understanding a phase transition, and we believe that what is of most interest in this re-examination of the lattice-animal based approach to percolation are these exponents and their relation to those more conventionally defined in percolation theory. We outline the approach in more detail, describing the presentation of the results as we do so. In Section 2, we describe the model, and define notations, before stating the combinatorial results that we will use. Theorem 2.2 asserts the existence of the function $f$ and describes aspects of its behaviour, and is a pretty standard result. The details of its proof are however cumbersome, and are not given here: they appear in [4]. Theorem 2.3 implies that
\[
\log f(\beta) \leq (\beta + 1) \log(\beta + 1) - \beta \log \beta \text{ for } \beta \in (0, 2(d-1)).
\]
F. Delyon [2] showed that equality holds for $\beta \in (0, 1/p_c - 1)$. Theorem 2.3 implies that the inequality is strict for higher values of $\beta$. The marked change, as $\beta$ passes through $1/p_c - 1$, in the structure of large lattice animals of surface-area-to-volume ratio $\beta$ is a combinatorial manifestation of the phase transition in percolation at criticality: a large lattice animal with surface-area-to-volume $\beta < 1/p_c - 1$ presumably has an internal structure resembling a typical portion of the infinite cluster at the supercritical value $p = 1/(1 + \beta)$ that corresponds to $\beta$, whereas, if $\beta > 1/p_c - 1$, there are too few large animals with surface-area-to-volume ratio $\beta$ to enable the formation of infinite structure in the percolation model at this corresponding value of $p$. We mention also that the notion of a collapse transition for animals has been explored in [3].

In Section 3, two scaling hypotheses are introduced, each postulating the existence of a critical exponent. One of the exponents, $\zeta$, describes how quickly $f(\beta)$ drops away from the explicit form given on the right-hand-side of (3) as $\beta$ rises above $1/p_c - 1$. The other, $\lambda$, describes how rapidly decaying in $n$ is the discrepancy between the critical value and that value on the subcritical interval at which the probability of observing an $n$-edged animal as the cluster to which the origin belongs is maximal. The first main result, Theorem 3.4, is then proved: the inequalities $\lambda < 1/2$ and $\zeta \lambda < 1$ cannot both be satisfied. In outline, this is because $\lambda < 1/2$ implies that, for values of $p$ just less than $p_c$, most of the weight of the sum in (2) is carried by terms indexed by $m >> na + n^{1/2}$, while $\zeta < 1/\lambda$ implies that the limiting function $f(\beta)$ has dropped enough in this range of $\beta = m/n$ that the probability of such lattice animals is
decaying quickly: we have reached beyond the low side of the critical scaling window. This
decay rate is quick enough that it implies that the mean cluster size is uniformly bounded on
the subcritical interval, but this contradicts known results. In fact, by a similar approach, it
may be shown that $\zeta < 2$ or $\lambda > 1/2$ provide sufficient conditions for the continuity of the
percolation probability (c.f. [4]).

In Section 4, we relate the value of $\zeta$ to an exponent of a more conventional nature in the
scaling theory of percolation, that of correlation size (see Theorem 4.2). Suppose that we
perform an experiment in which the surface-area-to-volume ratio of the cluster to which the
origin belongs is observed, conditional on its having a very large number of edges, for a $p$-value
slightly below $p_c$. How does the typical measurement, $\bar{p}$, in this experiment behave as $p$
tends to $p_c$? The value $\bar{p}$ tends to lie somewhere on the interval $(1/p_c - 1, 1/p - 1)$. In Theorem
4.3, we determine that there are two possible scaling behaviours. The inequality $\zeta < 2$ again
arises, distinguishing the two possibilities. If $\zeta < 2$, then $\bar{p}$ scales much closer to $1/p_c - 1$
while if $\zeta > 2$, it is found to be closer to $1/p - 1$. It would be of much interest further to
understand the relation of $\zeta$ and $\lambda$ to other exponents.

2 Notations and combinatorial results

Throughout, we work with the bond percolation model on $\mathbb{Z}^d$, for any given $d \geq 2$. This model
has a parameter $p$ lying in the interval $[0, 1]$. Nearest neighbour edges of $\mathbb{Z}^d$ are declared to be
open with probability $p$, these choices being made independently between distinct edges. For
any vertex $x \in \mathbb{Z}^d$, there is a cluster $C(x)$ of edges accessible from $x$, namely the collection of
edges that lie in a nearest-neighbour path of open edges one of whose members contains $x$ as
an endpoint.

**Definition 2.1** A lattice animal is the collection of edges of a finite connected subgraph of $\mathbb{Z}^d$.
An edge of $\mathbb{Z}^d$ is said to be outlying to a lattice animal if it is not a member of the animal, and
if there is an edge in the animal sharing an endpoint with this edge. We adopt the notations:

- for $n, m \in \mathbb{N}$, set $\Gamma_{n,m}$ equal to the collection of lattice animals in $\mathbb{Z}^d$ one of whose edges
  contains the origin, having $n$ edges, and $m$ outlying edges. Define $\sigma_{n,m} = |\Gamma_{n,m}|$. The
  surface-area-to-volume ratio of any animal in $\Gamma_{n,m}$ is said to be $m/n$.

- for each $n \in \mathbb{N}$, define the function $f_n : [0, \infty) \to [0, \infty)$ by
  $$f_n(\beta) = (\sigma_{n,\lfloor \beta n \rfloor})^{1/n}$$

On another point of notation, we will sometimes write the index set of a sum in the form $nS$, with $S \subseteq (0, \infty)$, by which is meant $\{m \in \mathbb{N} : m/n \in S\}$.

We require some results about the asymptotic exponential growth rate of the number of lattice
animals as a function of their surface-area-to-volume ratio. We now state these results, noting
that the following theorem appears as Theorem 2.1 in [4], which paper gives its proof.

**Theorem 2.2**

1. For $\beta \in [0, \infty) \setminus \{2(d-1)\}$, $f(\beta)$ exists, being defined as the limit $\lim_{n \to \infty} f_n(\beta)$.
2. For $\beta > 2(d-1)$, $f(\beta) = 0$.
3. For $\beta \in (0, 2(d-1))$, $n \in \mathbb{N}$, $f_n$ satisfies $f_n(\beta) \leq L^{1/n}n^{1/n}f(\beta)$, where the constant $L$
   may be chosen uniformly in $\beta \in (0, 2(d-1))$. 

4. \( f \) is log-concave on the interval \((0, 2(d - 1))\).

**Remark:** The proof involves concatenating two large lattice animals of the same surface-area-to-volume ratio \( \beta \in (0, 2(d - 1)) \) by translating one so that it just touches the other. This operation produces a new lattice animal with roughly this same surface-area-to-volume ratio. In this way, some part of the set \( \Gamma_{2n, [\beta n]} \) is composed of concatenated pairs of animals each lying in \( \Gamma_{n, [\beta n]} \), if we overlook the errors that the joining produces. It would follow that \( \sigma_{2n, [\beta n]} \geq 2n^{-1} \sigma_{n, [\beta n]}^2 \), the factor of \( 2n^{-1} \) occurring because, in performing the argument carefully, we work with the space of lattice animals up to translation rather than those containing the origin, this alteration producing some factors of \( n \). The proof demonstrates that the errors involved in joining are indeed negligible. In this way, we obtain the existence of the limit \( f(\beta) \), and the bound in the third part of the theorem. The proof of the fourth part is a reprisal of the same argument that instead involves concatenating two lattice animals of differing surface-area-to-volume ratio, with their relative sizes chosen to ensure a given surface-area-to-volume ratio for the resulting lattice animal. More specifically, for \( \beta_1, \beta_2 \in (0, 2(d - 1)) \) satisfying \( \beta_1 < \beta_2 \), and for \( \lambda \in (0, 1) \), we would show that
\[
\log f(\lambda \beta_1 + (1 - \lambda) \beta_2) \geq \lambda \log f(\beta_1) + (1 - \lambda) \log f(\beta_2),
\]
by concatenating a pair of animals drawn from the sets \( \Gamma_{[\lambda n], [\beta_1 \lambda n]} \) and \( \Gamma_{[(1 - \lambda) n], [\beta_2 (1 - \lambda) n]} \), the resulting animal lying in \( \Gamma_{n, [(\lambda \beta_1 + (1 - \lambda) \beta_2) n]} \) provided that we again tolerate the slight discrepancy caused by the joining mechanism, as well as some rounding errors.

The second part of the theorem follows from the fact, easily proved by an induction on \( n \), that a lattice animal in \( \mathbb{Z}^d \) of size \( n \) may have at most \( 2(d - 1)n + 2d \) outlying edges.

**Theorem 2.3** Introducing \( g : [0, 2(d - 1)] \to [0, \infty) \) by means of the formula
\[
f(\beta) = g(\beta) \frac{(\beta + 1)\beta^{\beta + 1}}{\beta^\beta},
\]
we have that
\[
g(\beta) \begin{cases} 1 & \text{on } (0, \alpha], \\ < 1 & \text{on } (\alpha, 2(d - 1)), \end{cases}
\]
where throughout \( \alpha = 1/p_c - 1 \), \( p_c \) being the critical value of the model.

**Remark:** The assertion that \( g = 1 \) on \( (0, \alpha] \) was originally proved by Delyon [2]. For the sake of completeness, however, we will give a proof of this result.

We will make use of the following weaker result in the proof of Theorem 2.3.

**Lemma 2.4** The function \( f : (0, 2(d - 1)) \to [0, \infty) \) satisfies
\[
\log f(\beta) \leq (\beta + 1) \log(\beta + 1) - \beta \log \beta
\]

**Proof:** We give a probabilistic proof, that uses the percolation model. The link between the random and combinatorial models is provided by (1), which we restate for convenience:
\[
\mathbb{P}_p(|C(0)| = n) = \sum m \sigma_{n,m} p^n (1 - p)^m
\]
Let \( \beta \in (0, 2(d - 1)) \). Choosing \( p = 1/(1 + \beta) \), and noting that the right-hand-side of the above equation is bounded above by one, yields
\[
\sigma_{n, [\beta n]} \leq \left( \frac{(\beta + 1)\beta^{\beta + 1}}{\beta^\beta} \right)^n \max \{1, \beta\},
\]
which may be rewritten
\[ f_n(\beta) \leq \frac{(\beta + 1)^{\beta + 1}}{\beta^\beta} \max \{1, \beta^{\frac{1}{2}}\}. \]

Taking the limit as \( n \to \infty \) gives that
\[ f(\beta) \leq \frac{(\beta + 1)^{\beta + 1}}{\beta^\beta}, \]
as required. □

We will also require the following lemma, to handle some expressions corresponding to a few miscellaneous lattice animals whose surface-area-to-volume ratio is almost maximal.

**Lemma 2.5** There exists \( r \in (0, 1) \) such that, for \( n \) sufficiently large and for \( m \in \{2(d - 1)n, \ldots, 2(d - 1)n + 2d\} \), we have that
\[ \sigma_{n,m} \leq \left(\frac{1 + \frac{m}{n}}{\frac{m}{n}}\right)^{n+m} r^n. \]

**Proof:** The inequality \( p_c > 1/(2d - 1) \) is known, a proof is supplied on [4, page 13]. There is an exponential decay rate in \( n \) for the probability of observing an \( n \)-edged cluster containing the origin in the subcritical phase [1]. Hence, for some \( r_j \in (0, 1) \) and for \( n \) sufficiently large, we have that
\[ \sigma_{n,2(d-1)n+j} \leq \left(\frac{(2d-1)n+j}{n}\right)^n \left(\frac{2d-1}{2d-1}n+j\right)^{2(d-1)n+j} r_j^n. \]

Setting \( r = \max_{j \in \{0, \ldots, 2d\}} r_j \) gives the result. □

**Proof of Theorem 2.3:** We firstly prove Delyon’s result, that \( g(\beta) = 1 \) for \( \beta \in [0, \alpha] \). By Theorem 2.2, we know that \( f \) is log-concave on \((0, \alpha)\) and, by Lemma 2.4, that on that interval, it satisfies
\[ f(\beta) \leq \frac{(\beta + 1)^{\beta + 1}}{\beta^\beta}. \]

From these statements and the assumption that Delyon’s result fails, it follows that there exist \( \beta_0 \in (0, \alpha) \) and \( \epsilon > 0 \) such that
\[ f(\beta) \leq \frac{(\beta + 1)^{\beta + 1}}{\beta^\beta} - \epsilon \quad \text{on} \quad (\beta_0 - \epsilon, \beta_0 + \epsilon). \] (4)

Set \( p = 1/(1 + \beta_0) \), and note that \( p > p_c \). We rewrite the right-hand-side of (1) as follows:
\[ \sum_m \sigma_{n,m} p^n (1 - p)^m = \sum_m \left( f_n(m/n) \frac{\beta_0^{\frac{m}{n}}}{1 + \beta_0^{1 + \frac{m}{n}}} \right)^n. \]

It follows that
\[ \mathbb{P}_p(|C(0)| = n) = \sum_{m \in nS_1} \left( f_n(m/n) \frac{\beta_0^{\frac{m}{n}}}{1 + \beta_0^{1 + \frac{m}{n}}} \right)^n + \sum_{m \in nS_2} \left( f_n(m/n) \frac{\beta_0^{\frac{m}{n}}}{1 + \beta_0^{1 + \frac{m}{n}}} \right)^{2(d-1)n+2d} + \sum_{m=2(d-1)n} \left( f_n(m/n) \frac{\beta_0^{\frac{m}{n}}}{1 + \beta_0^{1 + \frac{m}{n}}} \right)^n. \]
where

\[ S_1 = (\beta_0 - \epsilon, \beta_0 + \epsilon) \quad \text{and} \quad S_2 = \left( 0, 2(d - 1) \right) \setminus (\beta_0 - \epsilon, \beta_0 + \epsilon). \]

The behaviour of the three sums above will now be analysed, under the assumption that Delyon’s result is false. Firstly, we need a definition.

**Definition 2.6** Let the function \( \phi : (0, \infty) \to \mathbb{R} \) be given by

\[ \phi(\alpha, \beta) = (\beta + 1) \log(\beta + 1) - \beta \log \beta + \beta \log \alpha - (\beta + 1) \log(\alpha + 1). \]

**Remark.** That \( \phi \leq 0 \) is straightforward.

- The sum indexed by \( nS_1 \)
  
  We estimate
  
  \[
  \sum_{m \in nS_1} \left( f_n(m/n) \frac{\beta_0^{m/n}}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \sum_{m \in nS_1} \frac{f(m/n)}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \left( \frac{1 + m/n}{m/n} \right)^{1 + m/n} - \epsilon \right) \left( \frac{\beta_0^{m/n}}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \sum_{m \in nS_1} \exp \left( n [\phi(\beta_0, m/n) + \log(1 - c\epsilon)] \right) \right) \leq Ln(2en + 1)(1 - c\epsilon)^n,
  \]

  where the third part of Theorem 2.2 was applied in the first inequality, with (4) being used in the second. The constant \( c > 0 \) is chosen to satisfy \( \log c < (\beta_0 + \epsilon) \log(\beta_0 + \epsilon) - (\beta_0 + 1 + \epsilon) \log(\beta_0 + 1 + \epsilon) \).

- The sum indexed by \( nS_2 \)
  
  In this case, note that
  
  \[
  \sum_{m \in nS_2} \left( f_n(m/n) \frac{\beta_0^{m/n}}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \sum_{m \in nS_2} \frac{f(m/n)}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \left( \frac{1 + m/n}{m/n} \right)^{1 + m/n} \right) \left( \frac{\beta_0^{m/n}}{(1 + \beta_0)^{1 + m/n}} \right)^n \leq \left( \sum_{m \in nS_2} \exp \left( n\phi(\beta_0, m/n) \right) \right),
  \]

  where Lemma 2.4 was applied in the second inequality. The fact that

  \[
  \frac{d}{d\gamma} \phi(\beta_0, \gamma) = \log(1 + 1/\gamma) - \log(1 + 1/\beta_0)
  \]
implies that there exists $\delta > 0$ such that $\phi(\beta_0, \gamma) < -\delta$ for $\gamma \in S_2$. Hence
\[
\sum_{m \in nS_2} \left( f_n(m/n) \frac{\beta_0 n}{(1 + \beta_0)^{1+\frac{n}{\beta_0}}} \right)^n \leq 2(d-1)\text{L}n^2 \exp(-n\delta).
\]

- The sum indexed by $\{2(d-1)n, \ldots, 2(d-1)n + 2d\}$

Note that Lemma 2.5 implies that, for $n$ sufficiently large,
\[
\sum_{m=2(d-1)n}^{2(d-1)n+2d} \left( f_n(m/n) \frac{\beta_0 n}{(1 + \beta_0)^{1+\frac{n}{\beta_0}}} \right)^n \leq \sum_{m=2(d-1)n}^{2(d-1)n+2d} \left( (1 + \frac{m}{n})^{1+\frac{n}{\beta_0}} \left( \frac{\beta_0 n}{(1 + \beta_0)^{1+\frac{n}{\beta_0}}} \right) \right)^n r^n = \sum_{m=2(d-1)n}^{2(d-1)n+2d} r^n \exp(n(\phi(\beta_0, m/n)).
\]

We have demonstrated that if Delyon’s result fails, then
\[
\liminf_{n \to \infty} -\log P_p(|C(0)| = n) > 0.
\] (5)

The sharp first-order asymptotics in large size for the probability of observing a finite cluster in the supercritical phase of the percolation model were derived in [5]. This probability certainly decays at a subexponential rate. Since $p > p_c$ is in the supercritical phase, we find that the left-hand-side of (5) is zero. This contradiction completes the proof of Delyon’s result.

We must also show that, for $\beta \in (\alpha, 2(d-1))$, $g(\beta)$ is strictly less than one. For such $\beta$, let $p = 1/(1 + \beta)$. Note that $p < p_c$, and that
\[
P_p(|C(0)| = n) \geq P_p(C(0) \in \Gamma_{n, [\beta n]}) = |\Gamma_{n, [\beta n]}| \frac{\beta n}{(1 + \beta)^{n + [\beta n]}} = (f_n(\beta))^n \left( \frac{\beta n}{(1 + \beta)^{n + [\beta n]}} \right),
\]

Taking logarithms yields
\[
\frac{\log P_p(|C(0)| = n)}{n} \geq \log f_n(\beta) + \frac{\beta n}{n} \log \beta - (1 + \frac{\beta n}{n}) \log(1 + \beta),
\]
from which it follows that
\[
\liminf_{n \to \infty} \frac{\log P_p(|C(0)| = n)}{n} \geq \log f(\beta) + \beta \log \beta - (1 + \beta) \log(1 + \beta).
\] (6)

The right-hand-side of (6) is equal to $\log g(\beta)$, by definition. The exponential decay rate for the probability of observing a large cluster in the subcritical phase was established in [1]. Since $p < p_c$, this means the left-hand-side of (6) is negative. This implies that $g(\beta) < 1$, as required.

$\Box$
3 Critical exponents and inequalities

We introduce two scaling hypotheses, each of which postulates the existence of a critical exponent. We then state and prove the first main theorem, which demonstrates that a pair of inequalities involving the two exponents cannot both be satisfied.

3.1 Hypothesis (λ)

Definition 3.1 For each \( n \in \mathbb{N} \), let \( t_n \in (0, p_c) \) denote the least value satisfying the condition

\[
\sum_m \sigma_{n,m} t_n^n (1 - t_n)^m = \sup_{p \in (0, p_c]} \sum_m \sigma_{n,m} p^n (1 - p)^m.
\] (7)

That is, \( t_n \) is some point at or below the critical value at which the probability of observing an \( n \)-edged animal as the cluster to which the origin belongs is maximal. It is reasonable to suppose that \( t_n \) is slightly less than \( p_c \), and that the difference decays polynomially in \( n \) as \( n \) tends to infinity.

Definition 3.2 Define \( \Omega_+^{(\lambda)} = \{ \mu \geq 0 : \liminf_{n \to \infty} (p_c - t_n)/n^{-\mu} = \infty \} \), and \( \Omega_-^{(\lambda)} = \{ \mu \geq 0 : \limsup_{n \to \infty} (p_c - t_n)/n^{-\mu} = 0 \} \).

If \( \sup \Omega_-^{(\lambda)} = \inf \Omega_+^{(\lambda)} \), then hypothesis (λ) is said to hold, and \( \lambda \) is defined to be equal to the common value.

So, if hypothesis (λ) holds, then \( p_c - t_n \) behaves like \( n^{-\lambda} \), for large \( n \). We remark that it would be consistent with the notion of a scaling window about criticality that the probability of observing the cluster \( C(0) \) with \( n \)-edges achieves its maximum on the subcritical interval on a short plateau whose right-hand endpoint is the critical value. If this is the case, then \( t_n \) should lie at the left-hand endpoint of the plateau. To be confident that \( p_c - t_n \) is of the same order as the length of this plateau, the definition of the quantities \( t_n \) could be changed, in such a way that a small and fixed constant multiplies the right-hand-side of (7). In this paper, any proof of a statement involving the exponent \( \lambda \) is valid if it is defined in terms of this altered version of the quantities \( t_n \).

3.2 Hypothesis (ς)

This hypothesis is introduced to describe the behaviour of \( f \) for values of the argument just greater than \( \alpha \). Theorem 2.3 asserts that the value \( \alpha \) is the greatest for which \( \log f(\beta) = (\beta + 1) \log(\beta + 1) - \beta \log \beta \); the function \( g \) was introduced to describe how \( \log f \) falls away from this function as \( \beta \) increases from \( \alpha \). Thus, we phrase hypothesis (ς) in terms of \( g \).

Definition 3.3 Set \( \Omega_-^{(\varsigma)} = \{ \mu \geq 0 : \liminf_{\beta \to 0} (g(\alpha + \delta) - g(\alpha))/\delta^\mu = 0 \} \), and \( \Omega_+^{(\varsigma)} = \{ \mu \geq 0 : \limsup_{\beta \to 0} (g(\alpha + \delta) - g(\alpha))/\delta^\mu = -\infty \} \).

If \( \sup \Omega_-^{(\varsigma)} = \inf \Omega_+^{(\varsigma)} \), then hypothesis (ς) is said to hold, and \( \varsigma \) is defined to be equal to the common value.

If hypothesis (ς) holds, then greater values of \( \varsigma \) correspond to a smoother behaviour of \( f \) at \( \alpha \). For example, if \( \varsigma \) exceeds \( N \) for \( N \in \mathbb{N} \), then \( f \) is \( N \)-times differentiable at \( \alpha \).
3.3 Relation between $\lambda$ and $\zeta$

**Theorem 3.4** Suppose that hypotheses ($\zeta$) and ($\lambda$) hold. If $\lambda < 1/2$, then $\zeta \lambda \geq 1$.

**Proof:** We prove the theorem by contradiction, assuming that the two hypotheses hold, and that $\lambda < 1/2$, $\zeta \lambda < 1$. We will arrive at the conclusion that the mean cluster size, given by $\sum_n n \mathbb{P}_p(|C(0)| = n)$, is bounded above, uniformly for $p \in (0, p_c)$. That this is not so is proved in [1]. Note that

$$\sup_{p \in (0, p_c)} \sum_n n \mathbb{P}_p(|C(0)| = n) \leq \sum_n n \mathbb{P}_{t_n}(|C(0)| = n).$$

We write

$$\mathbb{P}_{t_n}(|C(0)| = n) = \sum_m \sigma_{n,m} t_n^n (1 - t_n)^m,$$

and split the sum in (8). To do so, we use the following definition.

**Definition 3.5** For $n \in \mathbb{N}$, let $\alpha_n$ be given by $t_n = 1/(1 + \alpha_n)$. For $G \in \mathbb{N}$, let $D_n = D_n(G)$ denote the interval

$$D_n = \left(\alpha_n - G\left(\log(n)/n\right)^{1/2}, \alpha_n + G\left(\log(n)/n\right)^{1/2}\right).$$

Now,

$$\sum_m \sigma_{n,m} t_n^n (1 - t_n)^m = C_1(n) + C_2(n) + C_3(n),$$

where the terms on the right-hand-side are given by

$$C_1(n) = \sum_{m \in D_n} \sigma_{n,m} t_n^n (1 - t_n)^m,$$

$$C_2(n) = \sum_{m \in (0,2(d-1)) - D_n} \sigma_{n,m} t_n^n (1 - t_n)^m$$

and

$$C_3(n) = \sum_{m \in \{2(d-1),\ldots,2(d-1)n+2d\}} \sigma_{n,m} t_n^n (1 - t_n)^m.$$ 

**Lemma 3.6** The function $\phi$ specified in Definition 2.6 satisfies

$$\phi(\alpha, \alpha + \gamma) = -\frac{\gamma^2}{2\alpha(\alpha + 1)} + O(\gamma^3).$$

**Proof:** We compute

$$\phi(\alpha, \alpha + \gamma) = -(\alpha + \gamma) \log(\alpha + \gamma) + (\alpha + 1 + \gamma) \log(\alpha + 1 + \gamma) - (\alpha + 1 + \gamma) \log(\alpha + 1) + (\alpha + \gamma) \log \alpha$$

$$= -(\alpha + \gamma) \log(1 + \gamma /\alpha) + (\alpha + 1 + \gamma) \log(1 + \gamma / (\alpha + 1))$$

$$= -(\alpha + \gamma) [\gamma /\alpha - \gamma^2 /2\alpha^2]
+ (\alpha + 1 + \gamma) \left[\gamma / (\alpha + 1) - \gamma^2 /2(\alpha + 1)^2\right] + O(\gamma^3)$$

$$= -\gamma^2 /[2\alpha(\alpha + 1)] + O(\gamma^3).$$
giving the result. □.

We have that
\[ X_n \mathbb{C}_2(n) = \sum_{m \in n((\alpha,2(d-1)) - D_n)} \left( \sum_{m \in n((\alpha,2(d-1)) - D_n)} (f_n(m/n) \frac{\alpha_{m/n}^{m/n}}{(1 + \alpha_n)^{1+m/n}})^n \right) \]
\[ \leq L \sum_{m \in n((\alpha,2(d-1)) - D_n)} \exp \left( n\phi_{\alpha_n,m/n} \right), \]
where the inequality is valid by virtue of Theorem 2.2 and the fact that \( g \leq 1 \). Lemma 3.6 implies that
\[ \sum_{m \in n((\alpha,2(d-1)) - D_n)} \exp \left( n\phi_{\alpha_n,m/n} \right) \leq (2(d - 1) - \alpha)n^{-K}, \]
where \( K \) may be chosen to be arbitrarily large by an appropriate choice of \( G \). It is this consideration that determines the choice of \( G \). The miscellaneous term \( C_3 \) is treated by Lemma 2.5. We find that the \( m \)-indexed summand in \( C_3(n) \) is at most
\[ r_n \exp \left( -n\phi_{\alpha_n,m/n} \right) \]
where the inequality is a consequence of Theorems 2.2 and 2.3. The fact that the function \( \phi \) is nowhere positive implies that
\[ C_1(n) \leq Ln \sum_{m \in nD_n} g(m/n)^n \]
Hence the desired contradiction will be reached if we can show that
\[ \sum_{n} \sum_{m \in nD_n} g(m/n)^n \]
is finite. As such, the proof is completed by the following lemma.

**Lemma 3.7** Assume hypotheses (c) and (\( \lambda \)). Suppose that \( \lambda < 1/2 \) and that \( \zeta \lambda < 1 \). Then, for \( \epsilon \in (0,1 - \zeta \lambda) \) and \( n \in \mathbb{N} \) sufficiently large,
\[ \sum_{m \in nD_n} g(m/n)^n \leq \exp \left( -n^{1-\zeta \lambda - \epsilon} \right). \]

**Proof:** Let \( \zeta^* > \zeta \) and \( \lambda^* > \lambda \) be such that \( \lambda^* < 1/2 \) and \( \zeta^* \lambda^* < \zeta \lambda + \epsilon \). By hypothesis (c), there exists \( \epsilon' > 0 \) such that
\[ \delta \in (0, \epsilon') \text{ implies } g(\alpha + \delta) - g(\alpha) < -\delta^{\epsilon^*}. \]
From Theorems 2.2 and 2.3, it follows that \( \sup_{\beta \in [\alpha + \epsilon', 2(d-1)]} g(\beta) < 1 \), which shows that the contribution to the sum in (10) from all those terms indexed by \( m \) for which \( m/n > \alpha + \epsilon' \) is exponentially decaying in \( n \). Thus, we may assume that there exists \( N_1 \) such that for \( n \geq N_1 \),
if \( m \in D_n^* \) then \( m/n - \alpha < \epsilon' \). Note that, by hypothesis (\( \lambda \)), \( \alpha_n - \alpha \geq n^{-\lambda^*} \) for sufficiently large. Hence, there exists \( N_2 \) such that, for \( n \geq N_2 \),

\[
\alpha_n - G(\log(n)/n)^{1/2} \geq \alpha + n^{-\lambda^*} - G(\log(n)/n)^{1/2} \geq \alpha + (1/2)n^{-\lambda^*}.
\]

For \( n \geq \max\{N_1, N_2\} \) and \( m \in nD_n^* \),

\[
g(m/n) \leq 1 - (m/n - \alpha)^{\xi^*} \leq 1 - (\alpha_n - G(\log(n)/n)^{1/2} - \alpha)^{\xi^*} \leq 1 - ((1/2)n^{-\lambda^*})^{\xi^*}.
\]

So, for \( n \geq \max(N_1, N_2) \),

\[
\sum_{m \in nD_n^*} g(m/n)^n \leq (2G(n\log(n))^{1/2})[1 - C'n^{-\lambda^*}\xi^*]^n,
\]

for some constant \( C' > 0 \). There exists \( g \in (0, 1) \), such that for large \( n \),

\[
[1 - C'n^{-\lambda^*}\xi^*]^n \leq g^{n^{-\lambda^*}\xi^*}.
\]

This implies that

\[
\sum_{m \in nD_n^*} g(m/n)^n \leq h^{n^{-\lambda^*}\xi^*} \text{ for large } n \text{ and } h \in (g, 1).
\]

From \( \xi^*\lambda^* < \xi\lambda + \epsilon \), we find that

\[
\sum_{m \in nD_n^*} g(m/n)^n \leq \exp n^{-\xi\lambda^* - \epsilon} \text{ for large } n,
\]

as required. \( \Box \)

**Remark:** It may be similarly shown that \( \xi < 2 \) or \( \lambda > 1/2 \) are sufficient conditions for the absence of infinite open clusters at the critical value \( p_c \). Except for some borderline cases, this leaves the region of the \( (\lambda, \xi) \)-plane specified by \( \xi > 2 \) and \( \xi\lambda > 1 \). Here, such a sufficient condition may be phrased in terms of the extent to which \( f_n(\beta) \) underestimates \( f(\beta) \) for a restricted range of values of \( \beta \), namely those that are roughly of the size \( \alpha + n^\lambda \). In this regard, bounds on the entropic exponent are relevant (see [6]). These results are stated and proved as [4, Theorems 4.1 and 4.3].

### 4 Scaling law

In this section, we examine the exponential decay rate in \( n \) for the probability of the event \( \{C(0) = n\} \) for \( p \) slightly less than \( p_c \) by our combinatorial approach. In doing so, we relate the quantity \( \xi \) to the exponent for correlation size, and see how the scaling behaviour for the typical surface-area-to-volume ratio of unusually large clusters in the marginally subcritical regime depends on the value of \( \xi \).

**Definition 4.1** Let \( q : (0, p_c) \rightarrow [0, \infty) \) be given by

\[
q(p) = \lim_{n \to \infty} \frac{-\log \mathbb{P}_p(|C(0)| = n)}{n}.
\]
Define $\Omega^{(\varrho)}_+ = \{ \gamma \geq 0 : \liminf_{p\downarrow p_c} \frac{q(p)}{p(p_c-p)} = \infty \}$ and $\Omega^{(\varrho)}_- = \{ \gamma \geq 0 : \limsup_{p\downarrow p_c} \frac{q(p)}{p(p_c-p)} = 0 \}$. If $\sup \Omega^{(\varrho)}_- = \inf \Omega^{(\varrho)}_+$, then hypothesis $(\varrho)$ is said to hold, and $\varrho$ is defined to be equal to the common value.

**Remark:** The existence of $\varrho$ follows from a standard subadditivity argument. The quantity $\varrho$ might reasonably be called the exponent for ‘correlation size’.

**Theorem 4.2** There exists $\delta' > 0$ and $p_0 \in (0, p_c)$ such that $p \in (p_0, p_c)$ implies that $q(p)$ is given by

$$q(p) = \inf_{\beta \in (\alpha, \alpha + \delta')} \left( - \log g(\beta) - \phi(1/p - 1, \beta) \right),$$

where the function $\phi : (0, \infty)^2 \to \mathbb{R}$ was specified in Definition 2.6. Recall also that $\alpha = 1/p_c - 1$.

**Proof:** We may write $\mathbb{P}_p(|C(0)| = n) = H_1 + H_2$, where

$$H_1 = \sum_{m=0}^{2(d-1)n-1} \sigma_{n,m} p^n (1-p)^m$$

and $H_2 = \sum_{m=2(d-1)n}^{2(d-1)n+d} \sigma_{n,m} p^n (1-p)^m$. \hfill (11)

Note that, by Lemma 2.5, there exists $r \in (0, 1)$ such that, for all $p \in (0, 1)$, $H_2 \leq (2d+1)r^n$. To treat the quantity $H_1$, note that

$$H_1 = \sum_{m = 0}^{2(d-1)n-1} a_n(m/n) \exp \left( n \left( \log g(m/n) + \phi(1/p - 1, m/n) \right) \right), \hfill (12)$$

where the quantity $a_n(\beta)$ for $\beta \in (0, 2(d-1))$ is given by the relation

$$\sigma_{n,|\beta n|} = a_n(\beta) f(\beta)^n.$$

Note that, by the third part of Theorem 2.2, $a_n(\beta) \leq Ln$ for such values of $\beta$. From this bound, and (12), it follows that

$$H_1 \leq 2(d-1)Ln^2 \exp \left( -n \gamma_p \right),$$

where $\gamma_p$ is given by

$$\gamma_p = \inf_{\beta \in (0, 2(d-1))} \left( - \log g(\beta) - \phi(1/p - 1, \beta) \right). \hfill (13)$$

From Theorem 2.3, we see that the function $\beta \to - \log g(\beta) - \phi(1/p - 1, \beta)$ is continuous on $(0, 2(d-1))$. Allied with the fact that for $\beta \in (0, 2(d-1))$, $\limsup_{n \to \infty} \frac{-\log a_n(\beta)}{n} \leq 0$, it follows that, for $\epsilon > 0$, and for $n$ sufficiently large, $H_1 \geq \exp \left( -n(\gamma_p + \epsilon) \right)$. Hence,

$$\lim_{n \to \infty} \frac{-\log H_1}{n} = \gamma_p. \hfill (14)$$
We now make the claim that there exists \( p_0 \in (0, p_c) \) and \( \delta' > 0 \) such that, for \( p \in (p_0, p_c) \), \( \gamma_p \) is given by

\[
\gamma_p = \inf_{\beta \in [\alpha, \alpha + \delta']} \left( - \log g(\beta) - \phi(1/p - 1, \beta) \right).
\]

(15)

Note that from

\[
-\frac{d}{d\beta} \phi(1/p - 1, \beta) = \log \left( 1 - 1/(1 + \beta) \right) - \log(1 - p),
\]

and \( p_c = 1/(1 + \alpha) \), it follows that the expression \( -\phi(1/p - 1, \beta) \) is decreasing in \( \beta \) on \( [0, \alpha] \), for \( p \in (0, p_c) \). Recalling from Theorem 2.3 that \( g(\beta) = 1 \) for each \( \beta \in [0, \alpha] \), it follows that, for \( p \in (0, p_c) \),

\[
-\log g(\alpha) - \phi(1/p - 1, \alpha) \leq -\log g(\beta) - \phi(1/p - 1, \beta).
\]

(16)

The fourth part of Theorem 2.2 implies that \( g : (0, 2(d - 1)] \rightarrow [0, \infty) \) is continuous. Using this fact and Theorem 2.3, we may, for a given \( \epsilon > 0 \), find \( \delta' > 0 \) such that

\[
\beta \in (\alpha + \delta', 2(d - 1)) \quad \text{implies that} \quad g(\beta) < 1 - \epsilon.
\]

(17)

Using \( g(\alpha) = 1 \), we may similarly choose \( \delta \in (0, \delta') \) such that

\[
\beta \in (\alpha, \alpha + \delta) \quad \text{implies that} \quad g(\beta) > 1 - \epsilon/2.
\]

Let \( p_0 = 1/(\alpha + 1 + \delta) \). For \( p \in (p_0, p_c) \),

\[
-\log g(1/p - 1) - \phi(1/p - 1, 1/p - 1) < -\log(1 - \epsilon/2),
\]

(18)

the second term on the left-hand-side being zero. From (17), we have that, for \( \beta \in (\alpha + \delta', 2(d - 1)) \),

\[
-\log g(\beta) - \phi(1/p - 1, \beta) \geq -\log(1 - \epsilon),
\]

(19)

since \( \phi \) is nowhere positive. We learn from (13), (16), (18) and (19) that, for \( p \in (p_0, p_c) \), (15) holds, as claimed. Note that

\[
\liminf_{n \to \infty} \frac{-\log H_2}{n} \geq -\log r,
\]

whereas, for \( p \in (p_0, p_c) \), it follows from (14), (15) and (18) that

\[
\limsup_{n \to \infty} \frac{-\log H_1}{n} < -\log(1 - \epsilon/2).
\]

By choosing \( \epsilon < 2(1 - r) \), we obtain for such values of \( p \),

\[
\lim_{n \to \infty} \frac{-\log P_p(|C(0)| = n)}{n} = \inf_{\beta \in [\alpha, \alpha + \delta']} \left( - \log g(\beta) - \phi(1/p - 1, \beta) \right),
\]

as required. \( \square \)

Theorem 4.2 allows us to deduce a scaling law that relates the combinatorially defined exponent \( \varsigma \) to one which is defined directly from the percolation model.

**Theorem 4.3** Assume hypothesis \((\varsigma)\).

- Suppose that \( \varsigma \in (1, 2) \). Then hypothesis \((\rho)\) holds and \( \rho = 2 \).
- Suppose that \( \varsigma \in (2, \infty) \). Then hypothesis \((\rho)\) holds and \( \rho = \varsigma \).
**Proof:** Suppose that $\xi \in (1, 2)$. Choose $\epsilon > 0$ so that $1 < \xi - \epsilon < \xi + \epsilon < 2$. There exists constants $C_1, C_2 > 0$ such that, for $p \in (p_0, p_c)$ and $\beta \in (\alpha, \alpha + \delta')$,

$$
(\beta - \alpha)^{\xi+\epsilon} + C_1(\beta - (1/p - 1))^2 \leq -\log g(\beta) + -\phi(1/p - 1, \beta) \leq (\beta - \alpha)^{\xi-\epsilon} + C_2(\beta - (1/p - 1))^2.
$$

(20)

Applying Theorem 4.2, we find that

$$
(\beta_p - \alpha)^{\xi+\epsilon} + C_1(\beta_p - (1/p - 1))^2 \leq q(p),
$$

(21)

where $\beta_p \in [\alpha, \alpha + \delta']$ denotes a value at which the infimum in the interval $[\alpha, \alpha + \delta']$ of the first term in (20) is attained. Let $y_p = 1/p - 1 - \alpha$, and let $\sigma_p$ satisfy $\beta_p = \alpha + y_p^{\sigma_p}$. Then $\beta_p$ and $\sigma_p$ satisfy

$$
(\xi + \epsilon)(\beta_p - \alpha)^{\xi+\epsilon-1} = -2C_1(\beta_p - (1/p - 1))
$$

(22)

$$
(\xi + \epsilon)y_p^{\sigma_p(\xi+\epsilon-1)} = 2C_1(y_p - y_p^{\sigma_p}).
$$

Since $\beta_p \leq 1/p - 1, \sigma_p \geq 1$. From this and (22) follows $\liminf_{p \uparrow \sigma_p \geq 1/(\xi + \epsilon - 1)}$. Applying (22) again, we deduce that $\lim_{p \uparrow \sigma_p = 1/(\xi + \epsilon - 1)}$. Substituting $\sigma_p$ in (21) yields

$$
y_p^{\sigma_p(\xi+\epsilon)} + C_1(y_p - y_p^{\sigma_p})^2 \leq q(p).
$$

The facts that $\lim_{p \uparrow \sigma_p > 1}$ and $\lim_{p \uparrow \sigma_p(\xi+\epsilon)} = (\xi + \epsilon)/(\xi + \epsilon - 1) > 2$ imply that, for a small constant $c, c(p_c - p)^2 \leq q(p)$ for values of $p$ just less than $p_c$. A similar analysis in which $q(p)$ is bounded below by the infimum on the interval $[\alpha, \alpha + \delta']$ of the third expression in (20) implies that for large $C, q(p) \leq C(p_c - p)^2$, in a similar range of values of $p$. Thus hypothesis (a) holds, and $q = 2$.

In the case where $\xi > 2, \epsilon > 0$ be such that $\xi > 2 + \epsilon$. Defining $\sigma_p'$ by $\beta_p = 1/p - 1 - y_p^{\sigma_p'}$, we find that

$$
(\xi + \epsilon)(y_p - y_p^{\sigma_p'})^{\xi+\epsilon-1} = 2C_1y_p^{\sigma_p'}.
$$

(23)

Note that $\beta_p \geq \alpha$ implies that $\sigma_p' \geq 1$. From (23), it follows that $\liminf_{p \uparrow \sigma_p'} \geq \xi + \epsilon - 1$. Since $\xi + \epsilon - 1 > 1$, applying (23) again shows that the limit $\lim_{p \uparrow \sigma_p'} \sigma_p'$ exists and infact equals $\xi + \epsilon - 1$. Substituting $\sigma_p'$ in (20) yields

$$
(y_p - y_p^{\sigma_p'})^{\xi+\epsilon} + C_1y_p^{2\sigma_p'} \leq q(p).
$$

The fact that $\liminf_{p \uparrow \sigma_p'} > 1$ implies that $c(p_c - p)^{\xi+\epsilon} \leq q(p)$ for values of $p$ just less than $p_c$. Making use of the inequality $\xi > 2 + \epsilon$ in considering the infimum of the third term appearing in (20) yields in this case $q(p) \leq C(p_c - p)^{\xi-\epsilon}$ for similar values of $p$. Thus, since $\epsilon$ may be chosen to be arbitrarily small, we find that, if $\xi > 2$, then hypothesis (a) holds, and that $q = \xi$. \qed
